1908

U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus.

Weather Bureau—Willis L. Moore, *Chief.*
Bureau of Animal Industry—A. D. Melvin, *Chief.*
Bureau of Plant Industry—B. T. Galloway, *Chief.*
Forest Service—Gifford Pinchot, *Forester.*
Bureau of Soils—Milton Whitney, *Chief.*
Bureau of Chemistry—H. W. Wiley, *Chemist.*
Bureau of Statistics—V. H. Olmsted, *Statistician.*
Bureau of Entomology—L. O. Howard, *Entomologist.*
Bureau of Biological Survey—C. Hart Merriam, *Chief.*
Office of Public Roads—L. W. Page, *Director.*

Office of Experiment Stations—A. C. True, *Director.*

THE AGRICULTURAL EXPERIMENT STATIONS.

Alabama—
  College Station: *Auburn;* J. F. Duggar.[a]
  Canebrake Station: *Uniontown;* F. D. Stevens.[a]
  Tuskegee Station: *Tuskegee Institute;* G. W. Carver.[a]
Alaska—*Sitka:* C. C. Georgeson.[b]
Arizona—*Tucson:* R. H. Forbes.[a]
Arkansas—*Fayetteville:* W. G. Vincenheller.[a]
California—*Berkeley:* E. J. Wickson.[a]
Colorado—*Fort Collins:* L. G. Carpenter.[a]
Connecticut—
  State Station: *New Haven;* E. H. Jenkins.[a]
  Storrs Station: *Storrs;* L. A. Clinton.[a]
Delaware—*Newark:* H. Hayward.[a]
Florida—*Gainesville:* P. H. Rolfs.[a]
Georgia—*Experiment:* Martin V. Calvin.[a]
Hawaii—
  Federal Station: *Honolulu;* E. V. Wilcox.[b]
  Sugar Planters' Station: *Honolulu;* C. F. Eckart.[a]
Idaho—*Moscow:* H. T. French.[a]
Illinois—*Urbana:* E. Davenport.[a]
Indiana—*Lafayette:* A. Goss.[a]
Iowa—*Ames:* C. F. Curtiss.[a]
Kansas—*Manhattan:* C. W. Burkett.[a]
Kentucky—*Lexington:* M. A. Scovell.[a]
Louisiana—
  State Station: *Baton Rouge;*
  Sugar Station: *Audubon Park, New Orleans;*
  North La. Station: *Calhoun;*
  W. R. Dodson.[a]
Maine—*Orono:* C. D. Woods.[a]
Maryland—*College Park:* H. J. Patterson.[a]
Massachusetts—*Amherst:* W. P. Brooks.[a]
Michigan—*East Lansing:* R. S. Shaw.[a]
Minnesota—*St. Anthony Park, St. Paul:* E. W. Randall.[a]
Mississippi—*Agricultural College:* W. L. Hutchinson.[a]
Missouri—
  College Station: *Columbia;* H. J. Waters.[a]
  Fruit Station: *Mountain Grove;* Paul Evans.[a]
Montana—*Bozeman:* F. B. Linfield.[a]
Nebraska—*Lincoln:* E. A. Burnett.[a]
Nevada—*Reno:* J. E. Stubbs.[a]
New Hampshire—*Durham:* E. D. Sanderson.[a]
New Jersey—*New Brunswick:* E. B. Voorhees.[a]
New Mexico—*Agricultural College:* Luther Foster.[a]
New York—
  State Station: *Geneva;* W. H. Jordan.[a]
  Cornell Station: *Ithaca;* L. H. Bailey.[a]
North Carolina—
  College Station: *West Raleigh;* C. B. Williams.[a]
  State Station: *Raleigh;* B. W. Kilgore.[a]
North Dakota—*Agricultural College;* J. H. Worst.[a]
Ohio—*Wooster:* C. E. Thorne.[a]
Oklahoma—*Stillwater:* W. L. English.[a]
Oregon—*Corvallis:* J. Withycombe.[a]
Pennsylvania—
  State College: T. F. Hunt.[a]
  State College: Institute of Animal Nutrition, H. P. Armsby.[a]
Porto Rico—*Mayaguez:* D. W. May.[b]
Rhode Island—*Kingston:* H. J. Wheeler.[a]
South Carolina—*Clemson College:* J. N. Harper.[a]
South Dakota—*Brookings:* J. W. Wilson.[a]
Tennessee—*Knoxville:* H. A. Morgan.[a]
Texas—*College Station:* H. H. Harrington.[a]
Utah—*Logan:* E. D. Ball.[a]
Vermont—*Burlington:* J. L. Hills.[a]
Virginia—*Blacksburg:* S. W. Fletcher.[a]
Washington—*Pullman:* R. W. Thatcher.[a]
West Virginia—*Morgantown:* J. H. Stewart.[a]
Wisconsin—*Madison:* H. L. Russell.[a]
Wyoming—*Laramie:* J. D. Towar.[a]

[a] Director.

[b] Special agent in charge.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

Meteorology, Soils, and Fertilizers—W. H. BEAL.
Agricultural Botany and Vegetable Pathology—W. H. EVANS, Ph. D.
Field Crops—J. I. SCHULTE.
Horticulture and Forestry—E. J. GLASSON.
Zootechny and Human Nutrition—C. F. LANGWORTHY, Ph. D.
Agrotechny, Dairy Farming, and Dairying—R. D. MILNER
Agricultural Chemistry—W. H. BEAL, C. F. LANGWORTHY, and R D. MILNER.
Economic Zoology, Entomology, and Veterinary Medicine—E. V. WILCOX, Ph. D.
Rural Engineering—
Rural Economics—J. B. MORMAN.
Agricultural Education—D. J. CROSBY.

EDITORIAL NOTES.

	Page.
Quarter centennial of the New York State Station	1
Dr. G. C. Caldwell, deceased	4
Prof. W. O. Atwater, deceased	101
The Massachusetts conference on rural progress	106
Greater regularity in the management of station business	201
The enlarged duties and responsibilities of the station director	202
System *v.* red tape	204
Reorganization of the irrigation and drainage work	206
The oral instruction of the farmer	301
Aid to new settlers	303
The experiment stations and extension work	304
The position of agricultural chemistry in German universities	401
Agricultural instruction on the basis of the pure sciences	402
The modern basis of courses in agriculture	405
International Institute of Agriculture	501
Organ for the publication of agricultural research	503
Moral support for agricultural investigation	504
Changes in location of station men	601
Factors which contribute to desirability of position	603
Necessity for permanency in the human equipment	606
Carl von Voit, deceased	607
Agriculture in the National Education Association	701
Importance of investigations on the ash of feeding stuffs	801
The editing of station publications	805
Conference on the conservation of national resources	901
The agricultural appropriation act, 1908–9	905
Specialization in agricultural science	1001
Some noteworthy progress in physiological chemistry	1003
Third session of the Graduate School of Agriculture	1101

EXPERIMENT STATION RECORD.

VOL. XIX. SEPTEMBER, 1907. NO. 1.

Seven years ago the quarter centennial of the first experiment station established in this country was celebrated at New Haven, in connection with the annual convention of the Association of American Agricultural Colleges and Experiment Stations. It commemorated the beginning of an epoch-making public policy which has already resulted in quite as important advancement as science has ever wrought in any industry. This year is the twenty-fifth anniversary of four other stations—Massachusetts, New York, Ohio, and Tennessee—which, taken with the fact that three others had been established between 1875 and 1882, shows how steady was the growth of the experiment station idea.

The New York State Station observed its anniversary in field day exercises held on its grounds August 29. An attendance of over 3,000 filled to overflowing the large tent which had been erected for the occasion. The governor of the State lent encouragement by his presence and his words, giving public recognition of the significance of the anniversary to the State. The programme also included addresses by local members of Congress and the State legislature; representatives of the State department of agriculture and the State grange; President W. O. Thompson, of Ohio State University; and Dean Bailey, of Cornell University; together with an introductory address by the director, and remarks of a reminiscent nature by the sole surviving member of the board of control.

Following so closely upon the celebration of the fiftieth anniversary of the first agriculture college in this country, the exercises at Geneva were likewise of more than local significance. Popular attention was again forcefully directed to the substantial nature of agricultural progress during the last generation, and especially was opportunity afforded for emphasizing the influence of agricultural research in this development.

How great have been the advances in agricultural practice may be realized, in part, by reference to a brief summary appearing in the first report of the station and dealing with the conditions prevailing in New York at the time of its establishment. Agriculturally, as Doctor Jordan expressed it in his remarks, the period was one of transition from the sway of tradition and superstition to the domain of exact knowledge. During the seventies the work of the farm had become unexpectedly complex, and hindrances unknown to the earlier husbandry had increased the hazards attending farm practice. Many sections were suffering seriously from an exhaustion of the soil; new and unknown insects appeared in great numbers; noxious weeds multiplied with extreme rapidity, and unfamiliar diseases worked havoc in flocks and herds. The futility of individual experiment and the inadequacy of existing agencies in combating such conditions were in due season appreciated, and led to a demand for the State to cope with the problem. The result was the provision, in 1880, for an agricultural experiment station as a State institution, for the purpose of "promoting agriculture in its various branches by scientific investigation and experiment," and its actual commencement of work in the spring of 1882.

Although experiment stations were already in existence in California, Connecticut, New Jersey, and North Carolina, and agricultural experimentation was slowly taking concrete form at a number of the agricultural colleges, the institution at Geneva found itself in many respects a pioneer. The prevailing model of the time was the German experiment station, in which a characteristic feature was the control work; and in the existing stations the inspection of fertilizers had usually been a prominent function from the start. At Geneva, however, such duties were not imposed until 1894, and by that time a spirit of strict adherence to the work of investigation, unhampered by routine analysis, had become well established.

A second divergence from the prevailing type was as to the form of organization. Instead of affiliation with an existing college or university as its research department, the institution was established, and has since been maintained, on an entirely independent basis, a circumstance insuring to its personnel exemption from the exactions of an undue amount of teaching and thereby favorable to concentration of effort.

A third distinctive feature was the liberal financial support accorded it at the outset. Instead of starting with an initial appropriation of $5,000 a year, as did its predecessors, much of which was of necessity expended for equipment, the Geneva Station received a maintenance appropriation of $20,000 a year, together with $30,000 for buildings and grounds, a substantial recognition of its needs and of the service expected of it. This gave it a distinct advantage in planning and organizing its work, and the continuance of this generous support as the needs and activities of the station have grown has been no small factor in its consistent development. To-day its annual income aggregates over $90,000, of which but $2,400 is obtained from Federal sources, making it still, as in the beginning, the most liberally supported by the State of any of these institutions.

Still another important element which has made for prosperity at the station has been the character of its personnel. During the twenty-five years the position of director has changed but twice, and other positions in the station have enjoyed unusual freedom from change. From the time when Babcock, Goff, and Wing formed with the director its entire scientific staff, there has been maintained not merely a high degree of efficiency, but also a spirit of fidelity to high ideals of research. Not the least of the services of the station has been as a training ground for investigators, through whom its influence has been potent and widespread.

A comparison of the station of 1907 with that of 1882 exemplifies the remarkable expansion of activities which has characterized our progress during that time. From a scientific staff of four, representing the basal departments of agriculture, chemistry, and horticulture, the number of scientific and clerical workers has increased to thirty-one, with the establishment of new departments of animal industry, bacteriology, botany, dairying, and entomology. In addition, special officers are now necessary for exclusive attention to the general supervision of the work, the editing and mailing of the publications, and similar lines. Fifteen laboratory and other buildings are in use, with five more to be added in the near future. A few short articles sent out to newspapers of the State and a brief annual report of small circulation sufficed in the earlier days for the dissemination of the results of the station's work. At present the publications number about fifteen each year, most of which are reprinted in condensed popular form in editions of forty-five thousand copies.

With these improved facilities for service on the part of the station has developed a steadily increasing appreciation from the general public. The newly organized institution faced a constituency which, while hopeful, was none the less to a degree apprehensive that the new effort might be fanciful and visionary in its origin and would be impractical in its results. To-day, to quote again from Doctor Jordan, "the agricultural scientist feels that his right to live and labor is recognized. Members of our staff are listened to with respect and confidence, . . . and their advice is freely sought concerning troublesome farm problems." During the first year of the station's existence about 500 letters of inquiry were received. At present the number of replies sent out aggregates from 10,000 to 15,000 each year.

In fact, to such an extent has public interest developed that Doctor Jordan deemed necessary a word of warning. "It is," said he, "a real menace to research work that the worth to agriculture of the men of the colleges and stations is so largely judged by popular efforts. . . . If the members of this station staff were to meet all the calls they have for speaking and for visitation to different localities in the State, dust would settle on the crucible and the microscope." He took occasion to emphasize the importance of close adherence to thorough and scientific investigations as indispensable to the most satisfactory and permanent results.

A reason for the need of this careful concentration of activity in research was indicated by Governor Hughes in a speech warmly commendatory of the twenty-five years of patient, quiet, and effective effort of the station. In his opinion the scientific method, of which the station was to be regarded as an exponent, is to be defined as a patient, careful, persistent pursuit of truth—a fundamental principle which he declared of general application in all human affairs. "What we want," he went on to say, "is reason in agriculture. It is what we want in connection with every other field of noble effort. We want training, we want intelligence, we want scientific method, we want direction, we want the way shown, and then the man, in a way, can walk in it."

In an address on Lessons of the Day, Dean Bailey declared the fundamental purpose of the stations to be to increase the fertility and productiveness of the land. In his opinion a practical problem confronting them was the reclamation of the "abandoned farm," the economic aspects of which he discussed at length. A broad conception of the function of the stations was also shown in the address of President Thompson on National and State Aid to Investigation, who believed the principles underlying Federal legislation in their behalf to be based on the "general-welfare" clause of the Constitution.

Such evidence of progress in development, in our thinking and our ideals, and in public appreciation are gratifying to the stations as a whole and reflect credit on the efficiency and fruitfulness of our national system. Not until 1918 will its youngest member reach its twenty-fifth anniversary. Who would attempt to predict the development in the meantime?

Dr. George Chapman Caldwell, emeritus professor of chemistry in Cornell University and for many years prominently identified with the progress of agricultural chemistry in this country, died in a sanitarium September 5, at the age of 73 years. Doctor Caldwell was one of the early workers in agricultural experimentation in this country, a writer and lecturer upon various phases of agricultural science, and a specialist in the development and perfection of methods for agricultural analysis. His book entitled "Agricultural Chemical Analysis," issued in 1869, was a pioneer and long remained the standard work in English upon that subject.

Doctor Caldwell brought to his life work a broad and thorough training, gained at the Lawrence Scientific School of Harvard and the universities of Göttingen and Heidelberg. He received his doctor's degree from the former institution in 1857, being a student of the famous Wöhler at the time when the latter was at the height of his career. Returning to this country he was for a year assistant in chemistry at Columbia, professor of chemistry, physics, and botany at Antioch College, in Ohio, from 1859 to '62, and professor of chemistry in the Pennsylvania Agricultural College from '64 to '68. The interval between '62 and '64 was spent in the service of the United States Sanitary Commission. He was called to Cornell in 1868, being the first professor appointed in that institution, and remaining in active service for thirty-five years.

When the Cornell University Agricultural Experiment Station was organized in 1879 he was elected director, and the three reports published by the station contained many papers by him upon the results of fertilizer experiments, feeding experiments with cows and on maintenance rations for steers, the influence of feed on the composition of milk, sugar-beet culture, and methods of agricultural analysis. When the station was reorganized in 1887 he became chemist, and continued in that office until his retirement in 1902.

It was as a teacher quite as much as an investigator that Doctor Caldwell contributed to the advancement of agricultural science and practice. To a large number of students he opened up the needs and possibilities of agricultural investigation and gave an inspiration to enter that field in the search for truth. Upon these he impressed an intelligent appreciation of the requirements of that work, especially the necessity for thoroughness and exactness in plan and method at every stage of the undertaking. Although not active for several years past, owing to failing health, his work has been continued in the students who have gone out from his instruction into experiment station work, and who have carried to it the zeal and the love for truth which he imparted.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Chemical method for the determination of the available phosphoric acid in soils, A. DE 'SIGMOND (*Jour. Amer. Chem. Soc., 29 (1907), No. 6, pp. 929-936, fig. 1*).—The author here briefly describes the method which he has used for the determination of the available phosphoric acid in soils in connection with an elaborate study of the fertilizer requirements of Hungarian soils for which he was awarded a prize by the Hungarian Academy of Sciences. The method is as follows:

"1. *The determination of the basicity of the soil.*—Titrating 25 gm. of soil with a standard solution of nitric acid, containing 100 mg. N_2O_5 per liter, and boiling the soil, to drive out all the carbonic acid, we get at the basicity of the soil, that is the amount of nitric acid neutralized by the soil. The author uses the term basicity for the number of milligrams N_2O_5 for complete neutralization of 25 gm. of the soil.

"Weigh 25 gm. air-dried soil in a beaker, add a small amount of water and 10 cc. of the standard nitric-acid solution. Then boil the solution until the carbonic acid escapes, test with litmus paper, and if the reaction is not distinctly acid, add again 10 cc. of nitric acid, boil, and test again with litmus paper. Repeat this until there is a distinct excess of acid. Then pour the whole contents of the beaker into a standard flask of 500 cc., fill up, shake, filter, and determine in 50 cc. the excess of acid with a standard solution of potassium hydroxid such that 1 cc. neutralizes 10 mg. N_2O_5. Use methyl orange as indicator. By calculating the number of milligrams of N_2O_5 neutralized by 25 gm. of soil, we get the basicity of the soil.

"With soils which on adding some acid effervesce distinctly, the author has found it better to use only 5 gm. instead of 25 gm

"2. *Making of the soil solution.*—In making the soil solution, we wish to get a solution with an end acidity ranging 200 to 1,000 mg. N_2O_5 per liter of the soil solution. The end acidity means the acidity of the soil solution after the solution is ready for the determination of phosphoric acid.

"From the basicity of the soil we can nearly calculate the amount of standard acid wanted for the soil solution, namely:

"(1) If the soil contains practically no traces of carbonates, or the basicity runs below the value of 1,000 mg. N_2O_5, use but 10 cc. of the standard nitric acid solution to 25 gm. of soil.

"(2) If the soil contains carbonates, but the basicity ranges but 1,000 to 4,000 mg. N_2O_5, use just as many cubic centimeters of the standard acid as are required for the full neutralization of the basicity of the soil to 25 gm. of soil.

"(3) If the soil is very much loaded with carbonates or the basicity runs above 4,000 mg. N_2O_5, and the soil is almost loamy or clay, use 5 to 10 cc. less of the standard acid than would be required for the complete neutralization of the basicity. But in the case of sandy and loose peaty soils the author has found it best to use the amount of acid according to (2).

"Now for making the soil solution weigh 25 gm. of air-dried soil in a standard flask of one liter, add about 100 cc. distilled water and standard nitric acid according to the above-detailed rules. With soils rich in carbonates, take care of the effervescence; then fill up to 1,000 cc., close the flask, and put it in a rotary apparatus. After half an hour of slow rotation (one rotation lasting about one-half minute) take out the flask, carefully remove the stopper, and allow the solution to stand at room temperature (12 to 23°) for about 16 hours. Then put the flask again in the apparatus and rotate one-half of an hour again. Now filter the solution and take 25 cc. for the determination of the end acidity of the solution.

"This is done by titrating it with the above-mentioned standard potash solution, using methyl orange as indicator. If the end acidity would not fall between the 200 and 1,000 mg. N_2O_5 as wanted, repeat the preparation of the solution according to the results of the end acidity. If the end acidity is right, the solution is ready for the determination of the phosphoric acid.

"3. *The determination of phosphoric acid in the solution.*—Evaporate 800 cc. of the filtered solution to about 50 cc., using a small amount of a 20 per cent ammonium nitrate solution, for the precipitation of silicic acid. When the solution is evaporated as far as about 100 cc., filter, add 50 to 100 cc. ammonium molybdate solution, heat gently until the precipitation is complete, filter the solution, wash the precipitate with some nitric acid of 5 per cent, dissolve the molybdate precipitate with ammonia, add hydrochloric acid in excess, and again ammonia in excess, and precipitate with the usual magnesia mixture. The small amount of magnesium phosphate precipitates sometimes very slowly and 48 hours should be allowed for complete precipitation. Dry and burn the filter paper in a platinum crucible, ignite, and weigh the magnesium pyrophosphate as usual. The amount of P_2O_5 found, multiplied by 5, gives the per cent in the soil."

A comparison of the results obtained by this method and in fertilizer experiments on 94 Hungarian soils shows a very satisfactory agreement and indicates that the method furnishes a reliable index of the available phosphoric acid in the soil.

On the determination of potash in potash salts and mixed fertilizers by the modified Finkener method, H. NEUBAUER (*Ztschr. Analyt. Chem., 46 (1907), No. 5, pp. 311–314; abs. in Chem. Zentbl., 1907, II, No. 2, p. 182; Analyst, 32 (1907), No. 376, p. 273*).—A recent report by Kling and Engels on tests of the author's modification of this method (E. S. R., 18, p. 108) is referred to and certain improvements of the method, particularly for the determination of potash in mixed fertilizers, are described.

The present form of the author's method for the determination of potash in mixed fertilizers is as follows: Boil 10 gm. of the substance in a 500 cc. flask with about 300 cc. of water, then add a drop of phenolphthalein and sufficient dilute milk of lime to produce a decided red color. After a few minutes add enough oxalic acid to destroy the red color. Cool, fill the flask to the mark, mix, and filter. Evaporate 25 cc. of the filtrate corresponding to 0.5 gm. of substance to dryness in a platinum dish and heat almost to glowing to remove ammonium salts. Take up the residue in water, add a little hydrochloric acid and digest on the water bath with trituration until any floccules of calcium sulphate or silica which may be present are dissolved. Pass through a small filter into a porcelain dish and evaporate with platinum chlorid for determination of potash in the usual way, the reduced platinum being purified by washing with hot 10 per cent nitric acid.

The determination of water in proteids, F. G. BENEDICT and CHARLOTTE R. MANNING (*Amer. Jour. Physiol., 18 (1907), No. 3, pp. 213–221*).—Animal and vegetable proteids are hygroscopic, so it is almost impossible to use anhydrous material for analytical purposes. Accurate determinations of the water content are therefore essential in reporting analyses.

"The usual custom of investigators has been to determine the moisture by heating in an air bath at 110° C., and as the results in this paper show, the determinations thus made may readily be subject to an error of 1 per cent. Obviously an error of 1 per cent or more in the water determinations would result in an error of one-half of 1 per cent in the carbon determinations, and a measurable error in the determination of nitrogen. It can only be said that in the majority of researches on the animal or vegetable proteins, the carbon and nitrogen determinations are in large measure only used for comparative observations, and hence the absolute nitrogen or carbon content is not of as great importance. It is clear, however, that at least so far as the materials used in these investigations are concerned, it is impossible to determine the moisture content in them by drying in hot air at a temperature of 100 to 110°.

"The removal of the final traces of moisture which are persistently retained by the proteins when dried in an air bath at a temperature of 110° can be effected by subsequent desiccation in a high vacuum for 2 weeks."

The detection and estimation of reducing sugars, S. R. Benedict (*Jour. Biol. Chem., 3 (1907), No. 2, pp. 101–117*).—From a study of methods of estimating sugar, the author recommends a copper-carbonate solution and gives directions for its preparation. For delicate work in sugar detection, either in pure solutions or in urine, the reagent should be freshly mixed and diluted.

The method outlined for the volumetric estimation of sugar requires a solution of crystallized copper sulphate in water, a solution of crystallized Rochelle salt with pure anhydrous sodium carbonate, and a solution of potassium sulphocyanid. "For use these solutions are mixed in equal proportions in the order indicated. To every 30 cc. of the solution thus obtained are added from 2.5 to 5 gm. of pure anhydrous sodium carbonate. The amount of this substance added should roughly correspond to the dilution to which the solution will be subjected during the titration, i. e., for titrating dilute sugar solutions add greater quantity of carbonate and vice versa. The solutions are mixed in a beaker of suitable capacity, the requisite quantity of carbonate added, and the mixture heated to boiling over a gauze until the carbonate completely dissolves. Thirty cc. of this mixture (equivalent to 10 cc. copper sulphate solution) are equal to approximately 0.073 gm. of pure dextrose.

"The titration is carried out as follows: The sugar solution is run in from a burette rather rapidly (not so rapidly as to interfere markedly with continuous vigorous boiling) until a heavy, chalk-white precipitate is formed and the color of the fluid begins to lessen perceptibly. The last portions should be run in in quantities of from 2 to 10 drops (depending on depth of color remaining and the relative strength of the sugar solution), with a vigorous boiling of about one-fourth minute between each addition. The end point of the reaction is the complete disappearance of the blue color. This point is sharp and satisfactory. The precipitate obtained is chalk-white and is rather an aid than a hindrance to the determination of the end point."

Separating starch and glycogen, E. Baur and E. Polenske (*Arb. K. Gsndht-samt., 24 (1906), No. 3, pp. 576–580; abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 2 (1907), No. 2, p. 79*).—In the examination of sausage a method of separating starch and glycogen is desirable, and that elaborated by the author depends upon the fact that glycogen is soluble in a saturated solution of ammonium sulphate, while starch is not. After filtration and dilution the glycogen is precipitated with alcohol. Comparative tests showed that the method gave satisfactory results.

The separation of carbohydrates by means of pure yeasts, J. König and P. Hörmann (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 3, pp. 113–132*).—A summary and discussion of experimental and other data regarding the use of yeast as a means for separating carbohydrates of different sorts. This method is most applicable, according to the authors, when a yeast can be found which has no action upon a given sugar, but attacks other sorts. Since estimating the amount of fermented sugars from loss of weight, as shown by carbon dioxid formed, does not furnish very accurate data, yeasts are especially satisfactory for the separation of glucose and maltose.

The determination of the sugar content of dried beet chips and sugar chips, F. Strohmer and O. Fallada (*Wchnschr. Cent. Ver. Rübenz. Indus. [Vienna], 45 (1907), No. 13, pp. 163, 164*).—A study of the comparative value of methods.

The Polenske number, M. Siegfeld (*Chem. Ztg., 31 (1907), No. 40, pp. 511–513*).—The author has studied the Polenske method of determining the presence of cocoanut oil in butter for a period of 2½ years, and in this article has summarized his results along with those of other investigators.

The Polenske number of the butter fat was increased to some extent by feeding cocoanut cake to cows and to a much greater degree by feeding beet tops and leaves. The author's compilation of 354 determinations of the Polenske number shows variations ranging from 1.20 to 5.30. The addition of considerable cocoanut oil would be required to raise the lowest number to the highest mentioned. It is therefore not believed by the author that the addition of small quantities of cocoanut oil, say 10 per cent, can be detected with certainty in this way. The method, nevertheless, is considered of great practical value.

Distillation device especially for nitrogen determination, C. Block (*Ztschr. Chem. Apparatenkunde, 2 [1907], pp. 46, 47, fig. 1; abs. in Chem. Zentbl., 1907, I, No. 11, p. 781*).—A check bulb through which runs the stem of a thistle tube for introducing alkali for neutralizing the acid in Kjeldahl determinations without danger of loss of ammonia, is described.

METEOROLOGY—WATER.

Treatise on the weather for farmers, P. Holdefleiss (*Witterungskunde für Landwirte. Stuttgart: Eugen Ulmer, 1907, pp. VII+84, figs. 14, charts 6*).—Among the topics discussed in this treatise are the importance of meteorology in agriculture, climate, the importance of weather predictions for the farmer, the making of meteorological observations in agriculture, including observations on rainfall, temperature of the air and of the soil, humidity of the air, winds, clouds, sunshine, atmospheric pressure, weather changes, and phenological studies.

Collected contributions from the field of meteorology and terrestrial magnetism, W. von Bezold and A. Coym (*Gesammelte Abhandlungen aus den Gebieten der Meteorologie und des Erdmagnetismus. Brunswick: F. Vieweg & Son, 1906, pp. VIII+448; rev. in Nature [London], 76 (1907), No. 1958, pp. 28, 29*).—These are the collected works of the eminent late head of the Prussian Meteorological Institute. The subjects treated include the phenomena visible after sunset (*Purpurlicht*); thunderstorms and sunspots; thermodynamics of the atmosphere; temperature and moisture conditions in cyclonic and anticyclonic weather; temperature, pressure, rainfall, cloud and magnetic potential around parallels of the earth; and the Gaussian theory.

Monthly Weather Review (*Mo. Weather Rev., 35 (1907), Nos. 3, pp. 103–154, figs. 10, charts 10; 4 pp. 155–205, figs. 31, charts 9*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of March and April, 1907, progress of climatology throughout the world, recent papers bearing on meteorology, recent addition to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 3.—Rainfall and Run-off of the Catskill Mountain Region (illus.), by T. Merriman (see p. 11); Variation of Precipitation in the Adirondack Region, by A. J. Henry; The Temperature in the Front and in the Rear of Anticyclones, up to an Altitude of 12 Kilometers, Compared with the Temperature in the Central Area (illus.), by H. H. Clayton; Bright Meteors; International and Local Organizations for the Promotion of Seismology; The Meteor of March 14, 1906, over Central New York, by H. A. Peck; Cooling by Expansion and Warming by Compression, by C. E. Peet; Espy's Nepheloscope; Meteorological Stations in Southern Rhodesia (illus.); A Cloud Bank at Sea; Normals in Weather Bureau Records; A Plea for the Teaching of Meteorology, by R. H. Curtis; On "Absolute" Values; Adam Paulsen (1833–1907); Weather Bureau Men as Educators; and Bells as Barometers.

No. 4.—The Mexican Earthquake of April 15, 1907, with Notes on the Nature of Movements Induced by Earthquakes, by C. F. Marvin; New Japanese Seismological Publications, by C. F. Marvin; Tornado of April 5, 1907, in Escambia County, Fla. (illus.), by W. F. Reed, jr.; A Proposed New Method of Weather Forecasting by Analysis of Atmospheric Conditions into Waves of Different Lengths (illus.), by H. H. Clayton (see p. —); Meteorology in the Physical Laboratory; Action of a Horizontal Air Current upon a Vertical Whirlwind, by B. Brunhes; Characteristics of the Intertropical Atmospheric Circulation; The Velocity of Centers of High and Low Pressure in the United States, by C. F. von Herrmann; A Course in Dynamic Meteorology; Weight of Sleet on Telegraph Wires and Trees; On the Depression in the Value of the Total Intensity of the Solar Radiation in 1903, According to Measurements made at the Central Station of the Polish Meteorological Service at Warsaw (illus.), by L. Gorczynski; The "Southwest" or "Wet" Chinook, by H. Buckingham, sr.; The "Dry" Chinook in British Columbia, by R. T. Grassham; The Wet and Dry Chinooks; The Hurricane of 1867 in the Bahamas; Notes for Teachers; Educational Notes; Weather Bureau Men as Educators; The International Aeronautical Conference of October, 1906, at Milan, by A. L. Rotch; and The Seismological Society of America.

Meteorological observations (*Alaska Stas. Rpt. 1906, pp. 68–75*).—Observations on temperature, precipitation, and cloudiness at Sitka, Kenai, Copper Center, Rampart, and other points in Alaska, are summarized for the latter part of 1905 and most of 1906.

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Met. Buls. 221, 222, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1907. The data are briefly discussed in general notes on the weather of each month.

Weather report for 1906, W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 29–31*).—Summaries of observations on temperature, precipitation, and frosts are given for Guelph and other stations in Ontario.

The climate of Calvert County [Md.], C. F. VON HERRMANN (*Baltimore: Johns Hopkins Press, 1907, pp. 167–206, figs. 4*).—The available meteorological data for this county are summarized and discussed.

A proposed new method of weather forecasting by analysis of atmospheric conditions into waves of different lengths, H. H. CLAYTON (*Mo.*

Weather Rev., 35 (1907), No. 4, pp. 161–168, figs. 28).—The more important conclusions reached by the author, after a study of this subject, are as follows:

"(1) That every meteorological element at any given place may be analyzed into a definite number of oscillations or waves differing in length, each of which appears to have a physical existence distinct from that of the others.

"(2) When analyzed in the same way for any given time, the data at widely separated stations near the same latitude show analogous waves, except that the maxima and minima differ somewhat in the time of occurrence at the different stations.

"(3) The waves, at least in temperate latitudes, drift generally from west to east—that is, the maxima and minima occur at eastern stations later than at western stations.

"(4) The velocity of drift is inversely proportional to the wave length. Fluctuations, or oscillations, completed in a short period of time, drift rapidly, while longer fluctuations drift more and more slowly in proportion as the time of oscillation is longer.

"(5) The speed of travel appears to be fairly constant from year to year for waves of the same length of oscillation measured in time.

"The discovery of these facts not merely opens the way to a great improvement in the forecasting of weather from day to day, but also, I believe, furnishes a scientific basis for long-range forecasting. The application of this knowledge to practical work is, however, not easy, because of the difficulty of analyzing and separating the different classes of waves. As a result of working at the matter for a number of years and carefully developing and testing methods of analysis and charting, I believe it is possible to improve the present forecasts and to make forecasts longer in advance, which would be of enormous advantage to agriculture and commerce."

Rainfall and run-off of the Catskill Mountain region, T. Merriman (*Mo. Weather Rev., 35 (1907), No. 3, pp. 109–118, figs. 6*).—This article summarizes the available rainfall data of the region covered by the 4 watersheds proposed to be used as an additional supply for the city of New York, and gives estimates of the probable mean annual rainfall of the watersheds as follows: "Esopus, 44 in.; Schoharie, 41 in.; Rondout, 48 in.; Catskill, 38 in."

Evaporation, W. H. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 31, 32*).—This is a continuation of the previous year's work on transpiration (E. S. R., 17, p. 841), and includes a further study of an instrument devised by the author for measuring evaporation. The data reported include observations in the thermometer shelter and at the surface of a reservoir. During the 6 months from June to November, the evaporation from the reservoir was 37.69 in., which is slightly over 10 in. in excess of the mean annual rainfall for the same place.

Damage by lightning in 1906, W. H. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 38–40*).—The usual summary of statistics on this subject is given.

Where the wind does the work, C. Cobb (*Nat. Geogr. Mag., 17 (1906), No. 6, pp. 310–317, figs. 10*).—The work of the wind on the low-lying islands and sand reefs of the coast of North Carolina is described, and means of checking the shifting of the sands are discussed.

Analyses of irrigation waters, A. L. Knisely (*Oregon Sta. Rpt. 1905, p. 67*).—Analyses of 5 samples of water used in irrigation experiments reported in Bulletin 86 of the station (E. S. R., 17, p. 90) are given.

Water for various crops, W. H. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), p. 33*).—The results of a continuation of measurements of the amount of water required by crops of wheat, barley, oats, and peas are reported.

Underground waters of coastal plain of Texas, T. U. TAYLOR (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 190, pp. 73, pls. 3*).—The region covered by this report, which is based upon data collected by personal visits and correspondence, includes the greater part of the coastal plain of Texas, comprising an area about 150 miles wide bordering the coast and extending across the entire State. Ground water is usually abundant throughout the district, and within recent years artesian wells have been obtained in various parts of the region, some of them furnishing sufficient flow for considerable irrigation. The depth at which artesian water can be obtained varies from a few feet to over 2,000 ft., averaging about 600 ft. The amount of flow varies from 20 to 1,600 gal. per minute.

The geology and water resources of the western portion of the Panhandle of Texas, C. N. GOULD (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 191, pp. 70, pls. 7, figs. 3*).—This report summarizes the results of a geologic and hydrographic reconnaissance made during 1903 and 1905 over a region of approximately 9,360 sq. miles in the western part of the Panhandle of Texas, including Sherman, Moore, Potter, Randall, Dallam, Hartley, Oldham, and Deaf Smith counties. Most of the underground water of this region is derived from the Tertiary deposits. It is almost uniformly soft and relatively pure and suitable for all domestic uses. The local precipitation is apparently the only source of the underground water. It is estimated that only about one-third of the rain sinks into the soil, adding about 18 in. to the ground water each year.

The Potomac River basin, H. N. PARKER ET AL. (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 192, pp. VI+364, pls. 10*).—This report describes all the conditions that affect the economic utilization of the water resources of this basin, dealing with the geographic history, rainfall and stream flow, pollution, occurrence of typhoid fever, character of the water, relation of soils and forest cover to the quality and quantity of the surface water, and the effect of industrial wastes on fishes.

The real cause of the drying up of springs in the basin of the Somme, HOUILLIER (*Ann. Dir. Hydraul. et Amélior. Agr., Min. Agr. [France], 1906, No. 31, pp. 238–243*).—The various causes which have been observed to contribute to the drying up of springs are briefly discussed, but it is maintained that in the particular case here reported it is not due primarily to diminution of rainfall, destruction of forests, or internal erosion of the soil, but to more complete utilization of the soil for agricultural purposes, resulting in greatly increased evaporation and transpiration through plants.

On the sinking of subterranean waters and the disappearance of springs, E. A. MARTEL (*Ann. Dir. Hydraul. et Amélior. Agr., Min. Agr. [France], 1906, No. 31, pp. 244–246*).—Brief notes are given on the causes of these phenomena.

The pollution and self-purification of ice (*Mo. Bul. N. Y. Dept. Health, 23 (1907), No. 2, pp. 2–6; abs. in Engin. News, 57 (1907), No. 17, pp. 454–456*).—This article reviews the various causes of pollution and discusses the agencies of self-purification—subsidence and oxidation (destroying 50 to 75 per cent of the bacteria); removal of suspended and dissolved matter by freezing (10 to 40 per cent); freezing (destroying 5 per cent of the bacteria in 1 hour, 90 in 24 hours, and practically all in 2 to 3 weeks); destruction of pathogenic germs when distributed through a large body of water (90 per cent in 30 to 60 days).

"It is thus evident why . . . ice pollution has been robbed of its apparent dangers and why the records show so few, if any, cases of epidemics of typhoid fever due to this mode of transmission. These facts, while emphasizing the great immunity bestowed by nature, point, however, to the real dangers of ice infection with renewed force. There still remains, for instance, the infection due to handling and distribution; to surface pollution due to the pernicious practice of flooding ice to get a thicker crop; to surface pollution due to rains and melting snow washing pollution from side slopes on to ice that has already formed; and, finally, to the dangers of artificial ice when this has been manufactured from contaminated water and delivered to consumers before the natural processes of purification have had an opportunity to become active or effective."

The prevention of stream pollution by strawboard waste, E. B. Phelps (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 189, pp. 29, pls. 2, figs. 2*).—This bulletin describes briefly the manufacture of strawboard and the methods of disposal of the waste liquor from this manufacture, and reports laboratory and field investigations in connection with a manufacturing plant at Urbana, Ohio, on methods of treatment of the waste to prevent pollution of streams.

The results of the experiments show that mechanical filtration through sand without coagulation and a short period of sedimentation remove over 90 per cent of suspended matter and yield an effluent which can be discharged into an equal volume of reasonably pure water without creating a nuisance.

"The sludge resulting from the sedimentation tanks, after pressing or spontaneous drying, is innocuous and makes good soil. It has some value as a fertilizer and is particularly valuable to mix with the clay soils of the Middle West to render them more porous." It is stated that the material contains a considerable proportion of calcium carbonate and 0.34 per cent of available phosphoric acid. "Other uses for this material are suggested, but they require further study."

Report of the commission on sewage irrigation of the city of Paris, Bourneville et al. (*Ann. Dir. Hydraul. et Amélior. Agr., Min. Agr.* [*France*], *1906, No. 31, pp. 173–180*).—The status in 1905 of the utilization of Paris sewage in irrigation on farms near the city, especially at Gennevilliers, with reference to pollution of the Seine, is briefly reported upon. It is made clear that the constantly increasing volume of sewage can not be cared for by irrigation alone.

Sewage and the bacterial purification of sewage, S. Rideal (*London: The Sanitary Publishing Co., Ltd.; New York: John Wiley & Sons, 1906, 3. ed., pp. XII+355, figs. 58*).—The revision of this third edition consists mainly in the incorporation of recent progress in bacterial methods of sewage disposal and the conclusions of the Royal Commission of Great Britain as far as they have been published (E. S. R., 16, p. 1032).

SOILS—FERTILIZERS.

Further studies on the properties of unproductive soils, B. E. Livingston et al. (*U. S. Dept. Agr., Bur. Soils Bul. 36, pp. 71, pls. 7*).—In continuation of previous investigations (E. S. R., 17, p. 340), studies of the occurrence in unproductive soils of substances deleterious to plant growth have been extended to a number of different soils, and observations have been made upon the effect of organic fertilizers on the toxic properties of soils and on the toxicity of ordinary distilled water.

The soils investigated in addition to the Takoma lawn soil used in previous experiments included a brownish yellow sandy loam subsoil from the Department grounds, Miami silt loam from the Rhode Island Experiment Station farm, and Volusia silt loam from the Ohio Station farm. The methods of investigation were substantially the same as those described in the previous bulletin. The main conclusions drawn from the results of this investigation are summarized as follows: "That toxic substances exist in these soils is apparent from several different lines of evidence. (1) Pure water is uniformly better suited to growing wheat seedlings for short periods than is the soil extract from the poor soils. It is also better suited to the preparation of a nutrient solution. (2) Finely divided, insoluble solids, when shaken with these extracts and then removed by filtering, generally produce a great improvement. Since the only conceivable way in which these can act is through their absorbing action, it is to be supposed that they owe their effect to the fact that they absorb, and thus remove from solution the toxic bodies existing in the extract. (3) The extracts of these soils are benefited by nutrient salts, especially sodium nitrate, but it is pointed out that these may be effective through some other means than the phenomena of nutrition. Certain nonnutrients, such as sodium chlorid, pyrogallol, and tannic acid, produce marked beneficial results. Since these can not act directly through nutrition, they must have some action either upon the toxic bodies, making them nontoxic, or upon the plant, causing it to become more or less immune to the toxic bodies. (4) The same chemicals have similar effects when added to the soil itself. Here the action is more difficult of analysis, but it seems probable that the chemicals act in the same general way as in the aqueous extract.

"The toxic substances here considered appear to be but slightly soluble in water; they are sometimes volatile with steam and sometimes not; the soil extracts containing them are usually more or less acid in reaction, but the acidity is not in itself the cause of their deleterious action; they are probably organic and are absorbed by finely divided solids.

"Evidence is presented to the effect that injurious materials similar to the ones existing in the soils are produced by the growth of wheat in water or sand cultures. Bodies of similar toxic action are also exuded from soaking wheat seeds, and, in some cases at least, may be washed from the bark and leaves of trees."

The experiments on the effect of stable manure and green manure on the toxicity of soils were made on the Takoma lawn soil and on the subsoil from the Department grounds. The results indicate that the beneficial effects obtained from the use of stable manure and green manure "are probably, in large part, due to the organic matters therein contained rather than to the salts carried into the soil by such treatments. That the organic matter is directly of use to plants as nutrient material is not probable; it appears to be beneficial largely through some action upon the soil constituents." It is suggested that the beneficial effects are due to action of the organic matter of the manures in so altering the toxic substances as to render them harmless.

In the course of the experiments referred to above it was found that distilled water, as ordinarily prepared and stored in the laboratory, has a decided toxic action on young plants. Simple redistillation in glass is not sufficient to correct this toxicity. It was found, however, that by shaking the water with finely divided and thoroughly clean carbon black of precipitated ferric hydrate and filtering, the quality of the water in this respect was very greatly improved.

The paraffined wire basket method of soil investigation of the Bureau of Soils, United States Department of Agriculture, C. E. Thorne (*Ohio Sta. Circ. 70, pp. 7*).—The attitude of the Ohio Experiment Station toward conclusions drawn by the Bureau of Soils from work in cooperation with that station by this method is defined in this circular.

Suggestions regarding the examination of lands, E. W. Hilgard (*California Sta. Circ. 25, pp. 7*).—The purpose of this circular is stated to be "to formulate some general explanations on the subject, which may in many cases enable the farmer to come to a definite forecast or conclusion, without individual consultation and advice; or, when this is not attainable, may so instruct him that he can forward to the station such definite statements of facts, and samples properly taken, as will convey the data needful for a full understanding of the situation."

Illinois soils in relation to systems of permanent agriculture, C. G. Hopkins (*Illinois Sta. Circ. 108, pp. 26*).—In this circular the author amplifies his well-known views regarding the maintenance of soil fertility by utilization of the nitrogen of the air through leguminous crops, the liberation of potassium from the soil supply, and the return to the soil of the phosphorus removed by crops, preferably in the form of insoluble phosphates, and explains in some detail the systems of soil management and cropping most likely to secure these results.

Soil surveys, F. B. Guthrie (*Agr. Gaz. N. S. Wales, 18 (1907), No. 5, pp. 438–443*).—This paper discusses briefly the use of soil analysis and more fully "the best means for carrying out a systematic examination of the soils of Australasia, on the lines on which such work is being carried out in other countries, or with such modifications as may be found most suitable to our conditions."

Particular emphasis is laid upon the importance of determining those properties which depend upon the physical character and texture of the soil. The purely chemical analysis is assigned a subordinate position and is limited to determinations of humus, total nitrogen, and of lime, potash, and phosphoric acid soluble in hydrochloric acid, and in special cases in other solvents. It is held that a determination of the rate of nitrification is of the greatest importance, and the method worked out by Ashby (E. S. R., 16, p. 452) and the oxidation method by Russell (E. S. R., 17, p. 536) are suggested for trial in the absence of any well-established method for this purpose.

Agricultural charts and the analysis of soils, A. Grégoire (*Bul. Soc. Chim. Belg., 21 (1907), No. 4, pp. 153–166*).—The author lays great stress upon the importance of the study of geological conditions and processes, and much less upon chemical analysis.

The agricultural value of the soils of central and western Africa, A. Hébert (*Quinz. Colon., 11 (1907), No. 4, pp. 131–135*).—The soils of this region are described on the basis of data secured by examinations of representative samples collected by Chevalier in his expeditions to the Lake Tchad region, French Guiana (E. S. R., 18, p. 426), the Island of St. Thomas, and the Gold Coast (E. S. R., 18, p. 532).

The soils of the Lake Tchad region are shown to be in general very sandy, very poor in phosphoric acid and potash, and particularly deficient in lime, but rich in sodium salts. The similarity in essential characteristics of the soils from different parts of the region indicates that they are of common origin and that the region was originally the bed of an inland sea, all of which, except Lake Tchad, has disappeared by evaporation.

The soils of the other regions show the same deficiencies as those of the Lake Tchad region.

In spite of the great deficiency, and in some cases almost total lack of potash, phosphoric acid, and lime in the soils of central and western Africa, the indigenous plants, including among others coffee (*Coffea excelsa*), cotton (*Gossypium anomalum*), and cacao, are able to assimilate the considerable amounts of these constituents needful for their vigorous growth. A direct connection between the deficiency of lime and the characteristic desert conditions of Sahara is traced.

The fertility of some colonial soils, as influenced by geological conditions, C. F. Juritz (*Agr. Jour. Cape Good Hope, 30 (1907), No. 4, pp. 454–476*).—Studies which have been carried on during the past 7 years in the government analytical laboratory of the Cape of Good Hope on soils from the southwestern districts of the colony are summarized. The averages for the various soil types are given in the following table:

Average results of chemical analyses of Cape of Good Hope soils.

Geological formation.	Number of soils analyzed.	Water.	Lime.	Potash.	Phosphoric acid.
Pre-cape rocks:		*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*

On the alkali soils of Middle Hungary, A. von Sigmond (*Wiener Landw. Ztg., 55 (1905), pp. 628, 629; abs. in Zentbl. Agr. Chem., 36 (1907), No. 2, pp. 133, 134*).—The origin and character of these soils are discussed.

Notes on some Java soils, W. Detmer and H. Immendorff (*Botanische und landwirtschaftliche Studien auf Java. Jena: Gustav Fischer, 1907, pp. 26–36*).—Chemical analyses and clay content of samples of soil and subsoil from cacao, cinchona, and tea plantations are compared with analyses of representative German soils. The most notable feature of these analyses is the high percentage of fertilizing constituents in the (good) tea soil (0.56 per cent of nitrogen, 0.16 per cent of phosphoric acid, 0.24 per cent of potash, and 0.66 per cent of lime).

Soils of Cambridgeshire, F. W. Foreman (*Jour. Agr. Sci., 2 (1907), No. 2, pp. 161–182*).—Physical and chemical analyses of typical soils of this district are reported. These analyses show in general a close relation between the mechanical and chemical character of the soils and the underlying formations.

Analyses of soils from old apple orchards, A. L. Knisely (*Oregon Sta. Rpt. 1905, pp. 65, 66*).—Analyses of samples of soil from old orchards and from adjacent fields, made with a view to determining whether the failure of such orchards is due to exhaustion of potash, are reported. The results show that the average potash content of the orchard soils (0.22 per cent) was not materially different from that of the adjacent fields (0.23 per cent). The author, therefore, concludes that "the stunted growth, lack of vigor, etc., are due much more to neglect than to a deficiency of plant food in the soil."

Soils of the Abitibi district, R. Harcourt (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 58–62*).—Analyses are reported of 18 samples of soil from this region, which occupies that part of the districts of Algoma and Nipissing lying between latitudes 49 and 51° N.

The results show that none of the soils are likely to be deficient in lime and most of them are abundantly supplied with it. The larger proportion of the soils is well supplied with potash and phosphoric acid. The nitrogen content is, as a rule, very low for soils which have never been cropped. The humus content is generally large, but it is evident that the decomposition of the organic matter has not yet proceeded very far.

From the results as a whole the general conclusion is drawn that "where drainage and cultivation receive due attention, much of the soil in the Abitibi district possesses sufficient plant food to grow many remunerative crops."

Soil analysis, W. H. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 35, 36*).—Mechanical analyses of 20 samples of soil from one farm are reported.

Soil acidity in its relation to lack of available phosphates, A. R. Whitson and C. W. Stoddart (*Jour. Amer. Chem. Soc., 29 (1907), No. 5, pp. 757–759*).—This is a preliminary report on investigations more fully presented elsewhere (E. S. R., 18, p. 1024).

Some mutual effects of tree-roots and grasses on soils, C. A. Jensen (*Science, n. ser., 25 (1907), No. 648, pp. 871–874*).—Data are presented which lead to the conclusion "that seedling trees of tulip, dogwood, maple, cherry, and pine retard growth of wheat when the latter is grown under conditions making it necessary for the wheat roots to be in close physical relation with the tree roots; that this retarding effect differs with different species of tree seedlings; that the checking of wheat growth is greatest during the season when the tree seedlings are most active physiologically, and this checking effect becomes less as the season of physiological inactivity of the trees is approached. That in the case of pine, at least, the live pine is much more detrimental to wheat growth than the dead pine.

"This injurious effect of trees on wheat appears to be due to the excretion of substances by the trees toxic to wheat growth."

Marly subsoils and the chlorosis or yellowing of citrus trees, E. W. Hilgard (*California Sta. Circ. 27, pp. 4*).—Cases of injury to citrus trees from calcareous subsoils are cited as an illustration of the necessity of carefully studying subsoils before planting orchards, and attention is called to the relation between native vegetation and the character of soil and subsoil as furnishing a practical means of judging soil conditions.

Treatment of peat soils, W. H. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 33–35*).—In continuation of experiments of the previous year (E. S. R., 17, p. 841), the effect of mixing various proportions of loam, lime, sand, and marl with peat was studied. It was found that peat treated with a moderate application of loam gave the best yield in both grain and straw of oats. Marl and lime were also beneficial, but sand was not.

Aeration of soils, W. H. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 36, 37*).—The effect of forcing air once a day through 4-gal. crocks of peat soil, in which wheat, barley, oats, peas, alfalfa, and soy beans were grown, are reported. The aerated wheat and barley did not seem to do quite as well as the unaerated. The other crops were, as a rule, benefited by aeration.

Soil temperatures (*Alaska Stas. Rpt. 1906, pp. 67, 68*).—Daily observations of temperature at 6 in. and 2 ft. below the surface of the ground and at 6 in. above, at Sitka, from May 20 to October 12 and at Kenai from May 17 to September 30, 1906, are recorded.

Seed inoculation, D. Finlayson (*Country Life [London], 21 (1907), No. 529, pp. 257–259, figs. 8*).—The history of investigation on this subject is briefly reviewed and experiments by Professor Bottomley, of Kings College, are reported. It is stated that 90 per cent of the 200 tests made with Professor Bottomley's cultures in different parts of Great Britain were successful. Some of the causes of failure are explained.

Commercial cultures of Pseudomonas radicicola, H. A. Harding and M. J. Prucha (*Abs. in Science, n. ser., 25 (1907), No. 647, p. 818*).—This is an abstract of a paper presented at the eighth annual meeting of the Society of American Bacteriologists, giving results of further tests by the New York State and other stations of commercial cultures of this organism dried on cotton, which have generally given unsatisfactory results. The use of metal containers to preserve the vitality of the cultures has been found ineffective.

On changes in a light sandy soil by sterilization, A. Koch and G. Lüken (*Jour. Landw., 55 (1907), No. 1, pp. 161–172*).—Observing that oats made much better growth on a sandy soil which had been sterilized than on one which had not been so treated, the authors made a study of the soil to determine the cause of the increased productiveness of the sterilized soil. It was found that the sterilized soil contained much more water-soluble organic matter and nitrogen than the unsterilized soil, while hydrochloric acid of 1.026 specific gravity dissolved 10 per cent of the total nitrogen of the sterilized soil as against 5 per cent of that of the unsterilized soil.

The authors, like other investigators, observed an injurious effect during the early periods of growth on the sterilized soil. These effects were observed first in zinc pots, but were afterwards noted in case of clay pots, especially when experiments were started in the spring. When the planting was done in early summer the higher temperatures apparently overcame any such injurious effects. The addition of calcium carbonate did not prevent injurious effects.

On new principles in soil studies, H. R. Christensen (*Tidsskr. Landbr. Planteavl, 13 (1906), pp. 145–198*).—A lecture delivered in the Royal Danish Agricultural Society, March 28, 1906, containing also a report on investigations on the occurrence and distribution of *Azobacter chroococcum* in Danish soils.—F. W. Woll.

Movements of certain bacteria in soils, K. F. Kellerman and Edna H. Fawcett (*Abs. in Science, n. ser., 25 (1907), No. 647, p. 806*).—The following abstract is given of a paper presented at the eighth annual meeting of the Society of American Bacteriologists:

"Two organisms have been studied in connection with *Pseudomonas radicicola, Bacillus ochraceous* and a form resembling *Bacillus coli*. The latter kills *Pseudomonas radicicola* when in synthetic nitrogen-poor sugar bouillon, but not in soil extracts of favorable soils; *Bacillus ochraceus* has little effect upon *Pseudomonas radicicola* under either condition.

"In sterilized favorable soils saturated with water *Bacillus ochraceus*, *Pseudomonas radicicola*, and the paracolon organism grow with almost equal speed, progressing about 1 inch in 48 hours. In soils barely moist *Pseudomonas radicicola* progresses at the rate of about 1 inch in 72 hours, while the two other forms are reduced to a rate of about 1 inch in 8 days. These experiments were all conducted at a temperature of 25° C. At a temperature of 10° C. the rate of *Pseudomonas radicicola* was reduced to 1 inch in 3 days in saturated soil; the two other organisms had made practically no growth at the end of 30 days.

"Under none of the conditions of these experiments did there seem to be any antagonism in the soil between *Pseudomonas radicicola* and *Bacillus ochraceus* or the paracolon organism."

The electro-chemical and electro-metallurgical industries in 1906, J. B. C. Kershaw (*Sci. Amer. Sup., 63 (1907), No. 1629, pp. 26098, 26099*).—This is a reprint of an article giving a brief review of the progress in these lines during the year. The part of particular interest from an agricultural standpoint is that relating to the development of processes for the manufacture of nitrogen compounds. The establishment of factories in Norway, Germany, Switzerland, France, and Italy for the manufacture of nitrogen compounds by either the Birkeland and Eyde or the Frank and Caro method is noted.

The utilization of atmospheric nitrogen for industrial purposes, P. F. FRANKLAND (*Jour. Soc. Chem. Indus., 26 (1907), No. 5, pp. 175–180, figs. 3*).—Various processes which have been proposed for this purpose are described.

Experiments with lime nitrogen, nitrate of soda, and sulphate of ammonia, E. WEIN (*Mitt. Deut. Landw. Gesell., 22 (1907), No. 13, pp. 128–134*).—Comparative tests of these fertilizers on barley, oats, and potatoes.

The movement of ammoniacal nitrogen in nature, P. EHRENBERG (*Mitt. Landw. Inst. Breslau, 4 (1907), No. 1–2, pp. 47–300, pls. 2, figs. 3*).—This is a critical monograph on this subject, including a very complete review of literature. It deals with the evaporation of ammonia from water, decomposing organic solutions and solids, soils, and ammoniacal substances spread on soils; the leaching out of ammonia; the transformation of ammonia into free nitrogen and nitric acid (nitrification); the chemical fixation of ammonia in soils and outside of them; the physical fixation of ammonia; the fixation of ammonia by lower plants; the taking up of ammonium compounds by higher plants; and the fixation of ammoniacal nitrogen by animals.

A series of experiments made with specially constructed apparatus to measure the amount of ammonia given off by soils with and without addition of ammoniacal compounds when a current of air is swept over them at uniform normal temperature (19–20°) is reported.

The conclusion is reached that only in case of sandy soils rich in calcium carbonate and poor in zeolithic compounds and humus is loss of ammonia by evaporation to be feared. Even in this case such loss occurs only when the summer temperature is very high, the soil dry, and the soil content of ammonia large, as in case of heavy applications of nitrogenous fertilizers. Practically, therefore, the loss from this source is insignificant.

In a series of pot experiments to study the question of assimilation of ammoniacal nitrogen by higher plants, the conclusion was reached that only nitric nitrogen is suited to the needs and will insure a normal development of the ordinarily cultivated higher plants. The assimilation of ammoniacal nitrogen assumes appreciable importance only in case of acid-soil and swamp-land plants.

Nitrogenous fertilizers, L. H. MANSHOLT (*Cultura, 19 (1907), No. 224, pp. 260–266*).—Comparative pot tests on oats of nitrate of soda, lime niter, and nitrogen-lime are reported.

Phosphates and phosphorus (*U. S. Geol. Survey Bul. 315, pp. 449–484, figs. 3, map 1; Amer. Fert., 26 (1907), Nos. 3, p. 21; 5, p. 17; Engin. and Min. Jour., 83 (1907), No. 25, p. 1191*).—The following papers on this subject are given in Contributions to Economic Geology, 1906, part 1, the first two being briefly noted in the other references given:

Phosphate deposits in Western United States, F. B. Weeks and W. F. Ferrier (pp. 449–462, figs. 3, map 1).—An account is given of the discovery, extent, and character of important oolitic deposits of phosphate in southeastern Idaho, southwestern Wyoming, and northeastern Utah. The deposits consist of alternating layers of black or brown phosphate, shale, and hard blue or gray compact limestone, mainly fossiliferous. The main bed so far developed is from 5 to 6 ft. thick and contains on an average 32 per cent of phosphoric acid.

Developed phosphate deposits of northern Arkansas, A. H. Purdue (pp. 463–473).—This is a brief account of the discovery, location and development, and character and extent of these deposits, a report on which by the Arkansas Station has already been noted (E. S. R., 14, p. 430). "While it is known that there is a phosphatic horizon of wide extent in northern Arkansas, the deposits have been developed at only one place, viz, on Lafferty Creek, in the western part of Independence County. . . . The developed deposits occur between the Polk Bayou Limestone and the St. Clair marble. . . . The phosphate rock is of sedimentary origin, and where developed is light-gray, homogeneous, and conglomeratic, the pebbles being the size of peas and smaller." Analyses are reported which show that the better specimens of the phosphate contain as high as 32 per cent of phosphoric acid.

Phosphorus ore at Mt. Holly Springs, Pa., G. W. Stose (pp. 474–483).—A deposit of wavellite (aluminium phosphate) at this place is described and its use for the manufacture of phosphorus is discussed.

Geological Survey publications on phosphates and other mineral fertilizers (p. 484).—A list of 20 publications on this subject is given.

On the changes which acid phosphates undergo under pressure or mechanical deformation, W. Spring (*Bul. Soc. Chim. Belg., 21 (1907), No. 3, pp. 91–103; Acad. Roy. Belg., Bul. Cl. Sci., 1907, No. 3, pp. 193–211*).—It was observed that the primary phosphates undergo a certain amount of decomposition under pressure or mechanical deformation, resulting, first, in the elimination of water of hydration and, finally, in the liberation of a certain quantity of phosphoric acid. The general effect is to facilitate reversion in certain phosphates. The primary phosphates of calcium, sodium, and probably lithium form molecular combinations with their respective sulphates. In the case of calcium compounds this molecular combination is apparently insoluble in water and its formation, therefore, contributes to the reversion of the acid phosphates of calcium.

The influence of phosphates on the circulation of potash in soils, C. Schreiber (*Rev. Gén. Agron., n. ser., 2 (1907), No. 3, pp. 97–110*).—Pot experiments with monocalcium phosphate and phosphatic slag on oats are reported from which the conclusions are drawn that both monocalcium phosphate and Thomas slag convert insoluble compounds of potash in the soil into soluble forms, the action of the Thomas slag in this respect being somewhat inferior to that of monocalcium phosphate. While the amount of potash thus set free in these experiments was considerable, it was not sufficient to render the use of potassic fertilizers unnecessary. It was found also that small applications of lime by setting free potash in the soil increased the effect of the phosphate. In large applications, however, lime rendered the phosphoric acid insoluble and depressed the yield in case of both monocalcium phosphate and slag, but less in case of slag than of superphosphate.

Algerian and Tunisian phosphates in 1906, Maizières (*Engrais, 22 (1907), No. 9, pp. 205–207*).—Statistics of the exploitation of these phosphate deposits are given.

Researches on glauconite, L. W. Collet and G. W. Lee (*Proc. Roy. Soc. Edin., 26 (1905–6), No. 4, pp. 238–278, pls. 12, map 1*).—This is a very complete study of the mineralogical character, physical properties, chemical composition, formation, association with phosphoric concretions, and distribution of this potassic silicate, which is of considerable agricultural importance in connection with deposits of phosphates and green sand marl. The article is in French.

A bibliography of 43 references to literature on the subject is given.

The use of potash salts on different soils and crops, Densch (*Illus. Landw. Ztg., 27 (1907), No. 11, pp. 83–85*).—This is a brief discussion of the adaptability of potash salts to different soils and crops.

Commercial fertilizers, W. J. Jones and O. C. Haworth (*Indiana Sta. Bul. 121, pp. 463–538, map 1*).—This bulletin summarizes the main provisions of the Indiana fertilizer law, discusses briefly the results of inspection, and gives in tabular form the analyses of 879 samples of fertilizers inspected during 1906. The large percentage of samples examined which were below the guarantee in composition indicates "a condition as regards mixing and composition which is far from what it should be."

Analyses of commercial fertilizers (*Kentucky Sta. Bul. 128, pp. 173–258*).—Analyses and valuations of 651 samples of fertilizers collected during 1906 are reported in tabular form, with brief explanatory notes.

Trade values and fertilizer and soil analyses, C. A. GOESSMANN and H. D. HASKINS (*Massachusetts Sta. Bul. 117, pp. 22*).—This contains a statement of trade values for 1906 and 1907, instructions regarding sampling, and analyses of miscellaneous samples of fertilizers, soils, etc., sent to the station for examination.

Inspection of fertilizers in 1906, F. W. MORSE (*New Hampshire Sta. Bul. 130, pp. 8*).—This bulletin reports the results of analysis of 114 samples of fertilizing materials inspected during the year.

[**Analyses of garbage ashes**], R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), p. 56*).—An analysis is reported of a sample of ashes from the garbage disposal plant of Toronto, which contained 6.5 per cent of lime, 1.9 per cent of potash, and 2.7 per cent of phosphoric acid.

Odorless fish fertilizer (*Amer. Fert., 26 (1907), No. 5, p. 13*).—It is stated that H. G. Deming, of the State University of Washington, has devised a process for preparing such a fertilizer, thus offering a means of saving the large amount of fish refuse which now goes to waste.

Mineral resources of the United States, calendar year 1905, D. T. DAY (*U. S. Geol. Survey, 1906, pp. 1403, fig. 1*).—Among the materials of special agricultural interest of which statistics of production and consumption are given as usual are lime, gypsum, marl, phosphate, potassium salts, and peat.

The fertilizers and feeding stuffs act of Great Britain (*Mark Lane Express, 96 (1907), Nos. 3928, p. 2; 3929, pp. 27, 28; 3930, p. 51; 3931, p. 85*).—The more important features of this act and of the rules and regulations adopted by the board of agriculture are summarized and explained.

The act requires the dealer to give the purchaser an invoice showing the percentages of nitrogen, soluble phosphates, insoluble phosphates, and potash in fertilizers. Cattle or poultry foods must be properly described by invoice according as they are prepared from one or more than one substance or seed, and if the food is artificial, percentages of oil and albuminoids must be stated. Such invoices are to be regarded as warranties, and advertisements and circulars containing statements regarding the character of the fertilizers or feeding stuffs are also to have the effect of warranties. Penalties for violations of the act are fines of from $50 to $250. The board of agriculture will have charge of the administration of the act through a chief agricultural analyst. (E. S. R., 18, p. 433.)

The fertilizers and feeding stuffs regulations, 1906 (*Jour. Bd. Agr. [London], 13 (1907), No. 10, pp. 604–615*).—The general regulations and those regarding sampling and limits of error agreed upon by the board of agriculture under the new fertilizer and feeding stuffs act are given.

The fertilizers and feeding stuffs act, J. A. VOELCKER (*Mark Lane Express, 96 (1907), Nos. 3935, p. 210; 3936, p. 241*).—The act is explained.

AGRICULTURAL BOTANY.

A contribution to the knowledge of correlation in plant metabolism, B. HANSTEEN (*Landw. Jahrb., 36 (1907), No. 2, pp. 267–308*).—The author has sought to ascertain the correlation between the phosphoric acid, magnesia, and potash taken up by plants at different stages of growth. About a dozen species of plants representing 5 different orders were studied and the phosphoric acid, magnesia, and potash content of roots, stems, cotyledons, endosperm, etc., were determined. The results of the analyses were discussed at length, the analytical data being given in detail.

The influence of light during germination on the assimilation of organic reserve material in seeds and bulbs, W. Lubimenko (*Compt. Rend. Acad. Sci.* [*Paris*], *144* (*1907*), *No. 19, pp. 1060–1063, dgm. 1*).—Wheat, oats, peas, white lupines, maize, and onions were grown under bell jars and the amount of light was regulated by covering the glass with varying thicknesses of white or black paper. The total growth, length, fresh and dry weight, etc., of the plants in each series was ascertained. The weight for the dry plants, grown under the different lights and intensities, is shown by curves from which it appears that while the water content varied but slightly, the dry weight of the different plants varied widely, depending upon the amounts of illumination.

The wheat, maize, pea, and onion plants increased in dry weight with increased illumination up to a maximum which about corresponded with the amount of light necessary for the beginning of chlorophyll formation. The dry weight of the wheat, peas, and onions grown in diffused light was greater than when grown in partial shade, but with maize, white lupines, and oats the dry weight was greatest for those plants grown under less light, and for lupines and oats the maximum dry weight was correlated with a minimum of light. The author concludes that the assimilation of reserve material stored in seeds and bulbs is influenced by the amount of light and that assimilation attains its maximum at about the amount of illumination required for the formation of chlorophyll. An increased illumination beyond this optimum is followed by diminished assimilation.

The development of chlorophyllous plants in the absence of carbon dioxid but with nontoxic quantities of amids, J. Lefèvre (*Rev. Gén. Bot.*, *18* (*1906*), *Nos. 208, pp. 145–163, fig. 1; 209, pp. 205–219; 210, pp. 258–280, figs. 4; 211, pp. 302–310*).—A series of experiments was conducted with cress and sweet basil grown in pots under bell jars without carbon dioxid but in the presence of a number of amids. The plants were supplied with chemical fertilizers to which was added a mixture of tyrosin, oxamid, glycocoll, alanin, and leucin at the rate of 1.1 gm. for every 500 gm. of soil.

The plants were observed under conditions of light and darkness, and it was found that in the presence of sunlight they were able to make considerable growth, attaining in 6 weeks a size fully 10 times that of the original, and with well-developed foliage and flower buds. As this growth took place in the entire absence of carbon dioxid, the carbon required must have come from the amids and was taken up by the roots. That the transfer was not simply osmotic, but true synthesis, is shown by the absence of all, or nearly all, growth when the plants were kept in the dark. Apparently photosynthesis took place in almost normal amount.

Carbonic acid assimilation and chlorophyll function, F. G. Kohl (*Ber. Deut. Bot. Gesell.*, *24* (*1906*), *Generalversammlungs-Heft, pp. 39–54*).—A résumé is given showing the present status of our knowledge relating to the assimilation of carbon dioxid and the chlorophyll function of plants.

The function of invertase in the formation of cane and invert sugar dates, A. E. Vinson (*Bot. Gaz.*, *43* (*1907*), *No. 6, pp. 393–407*).—In the studies made at the Arizona Experiment Station on the ripening of dates, the author has found that different varieties of these fruits have decidedly different chemical composition and that there appear to be well-established chemical mutants among date palms. These mutants originated long ago and are perpetuated by suckers. Whether they will transmit their differences through seedlings remains to be demonstrated.

In addition to the physical classification into hard and soft dates they may also be grouped into cane and invert sugar dates, the lines of the latter crossing those of the former, as the Deglet Noor is a typical cane sugar date, yet decidedly a soft one. The M'Kentichi Degla is a cane sugar date of the hard class. On the other hand, Saffraia, a typical hard date, is also an invert sugar date, and Halloui is a hard but only a partial cane sugar date.

Detailed studies were made of the variety Deglet Noor, a cane sugar date and a seedling invert sugar variety. It was found that the Deglet Noor shows an inclination toward cane sugar even in early stages, but from this point on it gains chiefly in cane sugar until ripeness is approached, when invert sugar takes its place. The amount of inversion seems to be influenced by the temperature to which the ripening date is subjected. The invert sugar date shows an increase parallel to the increase in dry matter. During the period of maximum ripening, when dry matter is accumulating very rapidly, cane sugar appears in considerable quantities. This is attributed to the formation of cane sugar at a greater rate than the invertase is capable of inverting it. Many varieties of dates have been examined and cane sugar is found to accumulate just before the softening of the fruit. At this time the invertase is readily extracted by solvents. The difference in behavior of the 2 classes of dates during ripening is believed to be due to the presence or absence of invertase.

The influence of tension on the formation of mechanical tissue in plants, R. P. Hibbard (*Bot. Gaz., 43 (1907), No. 6, pp. 361–382*).—The author conducted a series of experiments with sunflowers, beans, castor beans, cabbage, coleus, fuchsia, and vinca, subjecting the plants to tension and compression to determine the effect of these stimulants on the mechanical tissue. Contrary to the results by other investigators, but slight effects were noticed.

Of the stems tested for the increase of mechanical tissue under the influence of longitudinal pull, only that of vinca showed a response, and in this the increase was not great. Pull in the direction of the longitudinal axis of the plant caused a small increase in the tissue of the main and lateral roots of sunflowers and castor beans. Compression tension brought small increases of the mechanical tissue in the stems of fuchsia, vinca, and helianthus, but coleus gave no response.

Selection breeding of self-fertile plants, C. Fruwirth (*Arch. Rassen u. Gesell. Biol., 4 (1907), Nos. 2, pp. 145–170; 3, pp. 281–313*).—After describing various methods of breeding agricultural plants, their variability and powers of transmission of characters, the author reviews the results obtained by a number of investigators in selection and breeding. This is followed with detailed accounts of experiments conducted on the selection, breeding of peas, barley, oats, etc.

Concerning the self-sterility of some flowers, L. Jost (*Bot. Ztg., 1. Abt., 65 (1907), No. 5–6, pp. 77–117, pl. 1*).—Studies were made of a number of species of plants, among them *Corydalis cava*, *C. lutea*, *Secale cereale*, *Lilium bulbiferum*, *Hemerocallis flava*, *Cardamine pratensis*, *Cytisus* sp., and *Lupinus albus*, to determine the causes of the sterility of the flowers to their own pollen. The investigations included studies of pollen, structure of styles and stigmas, growth of pollen tubes in artificial solutions, in styles, etc.

A list of titles to the more important literature of the subject is given.

Notes on xenia, E. A. Bunyard (*Report of the Third International Conference, 1906, on Genetics. London: Roy. Hort. Soc., 1907, pp. 297–300*).—The author reports observations on xenia, or the influence of foreign pollen upon the maternal structure, and gives an account of experiments with maize, beans, peas, peaches, apples, etc. So far as his experience goes, he says that the occurrence of xenia as an influence of the pericarp is very rare, and that considerably more experimentation is needed to establish the phenomena on a firm basis of positive fact.

The occurrence of formaldehyde in plants, S. Nizza (*Malpighia, 20 (1906), No. 8–9, pp. 395–405*).—A considerable number of herbaceous and ligneous plants were tested by different methods to determine the presence of formaldehyde. It is claimed that Pollacci in 1899 showed that the presence of formaldehyde in plants was not due to the chlorophyll activity of the plant and was independent of solar energy. As a result of his studies, the author concludes that formaldehyde exists in the woody part of plants and its abundance is in proportion to the development of ligneous tissue. It is not found in the green parts of the plant, and its formation is independent of the presence of light or of the assimilatory processes of the plant. Formaldehyde is considered by the author to be an integral part of the woody tissues of plants and it is believed to originate in those tissues.

The recognition of glucosids in plants by means of emulsin, E. Bourquelot (*Arch. Pharm., 245 (1907), No. 3, pp. 172–180*).—A report is given of the examination of about 50 species representing 7 or 8 families of plants, to determine the presence of glucosids. Fresh and dried portions of plants were used. By the addition of emulsin to the macerated material and examination with the polariscope, the occurrence of glucosids was determined.

Linamarin, a cyanogenetic glucosid of flax, A. Jorissen (*Acad. Roy. Belg., Bul. Cl. Sci., 1907, No. 1, pp. 12–17*).—In this communication the author calls attention to a publication in which he announced in 1884 the presence of a cyanogenetic glucosid in flax to which he gave the name linamarin.

FIELD CROPS.

Annual report of Alaska Agricultural Experiment Stations for 1906 [Field crops], C. C. Georgeson (*Alaska Stas. Rpt. 1906, pp. 38–50, pl. 1*).—Brief notes are given on the crops grown at the various stations during the year.

Work at the Copper Center Station, J. W. Neal.—This station has now about 40 acres under cultivation and 80 acres of fenced pasture land. Alsike clover, alfalfa, *Agropyron tenerum*, *Festuca elatior*, *Holcus lanatus*, redtop, orchard grass, timothy, Essex rape, and *Bromus inermis* were grown in 20 by 60 ft. plats on a tract of heavy moist soil. Alsike clover and alfalfa did not give good results. *Agropyron tenerum* made a growth of 20 in. during the season and seemed very promising. Timothy also made a good growth and a yield of hay, amounting to 6,114 lbs. per acre, was secured. *Bromus inermis* was found valuable for spring pasture, but not profitable as a hay crop.

None of the different varieties of wheat grown matured seed. A better growth was secured on new ground summer-fallowed and fertilized with guano at the rate of about 400 lbs. per acre than on old ground cropped the year before without the use of fertilizer. In many instances the crop reached a height of 50 to 52 in.

Barley also grew best on the fertilized plat summer-fallowed. Grain was matured on only one well-protected plat. On other plats the crop was killed by frost August 24. Chevalier, Champion, Mansbury, and Odessa were apparently earlier than other varieties. On the best plats the crop stood from 40 to 45 in. high.

On light, dry soil in a protected location a small amount of oats matured. Finnish Black, Banner, Burt Extra Early, and Swedish Select were ripe enough to cut September 5 and 290 lbs. of seed were secured. Burt was the latest of these varieties, and Sixty-Day, which was still later, was nearly all killed by frost. Finnish Black on the summer-fallowed plat reached a height of from 50 to 58 in.

S. P. I. No. 11268 rye made a fine crop of hay from spring seeding, but did not proved to be a winter variety as is claimed. A fair stand of Amber rye lived through the winter and a few heads matured seed. Several varieties of winter wheat and rye were winterkilled.

Work at the Rampart Station, F. E. Rader.—At this station rye has never failed to winter successfully since 1900. This year Amber winter rye grew to an average height of 48 in. and produced short but well-filled heads, with plump grain. Giant French and Excelsior winter rye also gave good results. Kharkov winter wheat did much better than the year before and seemed more promising. Part of it was cut September 5 and the rest September 10.

The spring grains grown were barley, wheat, oats, rye, and buckwheat. These were sown the last days of May. Mansbury barley produced fine large heads and was harvested September 15. Lapland also grew well and ripened a little earlier than Mansbury. Two-rowed barley was ripe for cutting September 12. Saskatchewan Fife wheat did not develop further than the dough stage, and spring rye also failed to mature. Burt Extra Early oats ripened from September 1 to 15, when it was harvested, but the variety is not considered very desirable on account of its short, fine straw and small heads. Finnish Black oats is a tall variety with a large head and considered very desirable for that latitude if it can be made to mature earlier. Russian buckwheat was killed by frost August 25, when one-fourth of the crop was ripe. Early Rose potatoes, planted with the sprouts on the tubers, produced the largest tops and the most matured potatoes and yielded nearly twice as much as ordinary planting. Burbank from Rampart-grown seed grew well and produced good-sized tubers, the average yield being altogether about tenfold, and the quality good.

Of the different grasses under test, redtop, orchard grass, timothy, and velvet grass made the best growth.

Work at the Kenai Station, P. H. Ross.—Oats were grown for stock feed and made into hay when the grain was in the milk. A rank heavy growth was secured on an area treated with barnyard manure the year before, while on ground not so fertilized the growth was much lighter and thinner. Tall fescue, redtop, timothy, and meadow foxtail seeded in 1903 were cut for hay August 24, but no seed had ripened. Of the grasses seeded in 1904, tall fescue and tall oat grass were 40 in. high and blue grass 36 in. high on August 15. Smooth brome grass, hitherto one of the most thrifty grasses, did not grow well on account of the wet season. Of the grasses seeded in 1905, bluetop was from 48 to 60 in. high on August 15, bunch grass 30 in., timothy 40 to 60 in., and tall fescue 36 in. Bluetop, timothy, and bunch grass matured seed on soil well fertilized with barnyard manure. It was found that timothy needs barnyard manure as a soil dressing to make a good growth.

[Report of the] professor of field husbandry and experimentalist, J. BUCHANAN (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 164–176, 178–192*).—After giving a general outline of the work in his department, the author reports the results of experiments with a large number of different field crops. Practically all of the work reported is in continuation of previous investigations (E. S. R., 17, p. 851).

A comparison of different grain crops in progress for the past 5 years shows that the greatest yield of grain per acre, 2,739 lbs., was produced by barley, being followed by emmer with 2,714 lbs. In this same test the smallest yields by weight were produced by grass peas and spring vetches, the yields per acre amounting to 814 and 713 lbs., respectively.

A comparison of large, medium, and small-sized seeds of cereals, roots, and rape show that the large seeds surpassed the small seeds by 19.1 per cent for the cereal crops, 60.1 per cent for the root crops, and 40.3 per cent for the rape. The average of all results with plump and shrunken seeds of barley, spring wheat, and winter wheat show that the plump seed gave a yield of 20.2 per cent more than the shrunken seed.

Six-year tests with sound and broken seed of barley, winter wheat, and peas gave the following results: Barley, sound seed 53.8 bu., broken seed 46 bu.; winter wheat, sound seed 46.9 bu., broken seed 9.3 bu.; and peas, sound seed 29.2 bu., broken seed 10.2 bu.

Emmer and spelt were sown as early as the land could be cultivated in the spring and at intervals of 1 week afterwards until 8 different seedings had been made. In every instance emmer gave better results than spelt. Emmer produced the largest crop from its second seeding and spelt from its first. There was but little difference in the yields from the first 7 seedings of emmer, showing that this crop may be sown late in the season, while spelt must be sown as early as possible in the spring in order to get the best results.

In growing a mixture of grains for feeding purposes the largest yield of grain, 2,612 lbs. per acre, was obtained from a mixture containing 1 bu. of oats and 1½ bu. of barley. For an early ripening crop it was found that Daubeney oats and Mandscheuri barley made an excellent combination, while with Siberian or Banner oats, the later 2-rowed barleys, as Chevalier or Canadian, are to be preferred.

An experiment to ascertain the relative value of different kinds of grain when in a mixture, in comparison with the same grains when grown separately, showed that barley and oats produced the largest percentage of grains in the resulting crop, while emmer produced but a small percentage, showing that while it is a heavy yielder when grown alone it is not so well suited for growing in combination with other crops.

During the past 18 years 287 varieties of oats have been tested at the college, and among the 53 varieties which have been grown for the last 5 years 15 have given average yields of more than 100 bu. per acre, Banner standing first with 109 bu. Among the early varieties Daubeney is perhaps the most promising in yield and quality, while other good sorts are Prosperity, Alaska, and Early White Pearl.

Four standard varieties of 6-rowed varieties have now been tested for 17 years in succession, with the following results: Mandscheuri 70.6 bu., Oderbruck 64.2 bu., Common 6-rowed 61.9 bu., and Mensury 60.2 bu. per acre. California Brewing gave a somewhat larger yield than Mandscheuri in the average of the last 5 years, but its weight per measured bushel was only 46 lbs., as compared with 50 and 52.6 lbs. for most of the other varieties. The beardless varieties have given much lower yields of grain than the others and their grain is decidedly light in weight. Five of the best varieties of 2-rowed barley grown for 5 years gave the following yields: Iowa No. 5590, 72.3 bu.; Iowa No. 5591, 71.2 bu.; Jarman Selected, 71.2 bu.; and Selected Canadian Thorpe, 68.5 bu. per acre. Among the varieties of hulless barley tested for 5 years, Guy Mayle stood first with a yield of 53.2 bu. per acre, followed by Hungarian with 50.3 bu., and Black Hulless with 49.1 bu. The yields of hulless barley are reckoned at the rate of 60 lbs. per bushel. In 9 out of the past 14 years fair yields of winter barley have been secured at the station, but in the other 5 years the crop was almost completely winterkilled.

Among 61 varieties of winter wheat grown in 1906, Abundance stood first in yield with 50.4 bu., and Prize Taker second with 50.2 bu. These 2 varieties are both white wheats, very closely resembling the Dawson Golden Chaff. Russian

Amber and Imperial Amber, 2 comparatively hard red wheats, came up to third and fourth places in yield of grain with 49.8 and 49.4 bu. per acre, respectively. All 4 varieties were over the standard in weight. The varieties giving the highest weight per measured bushel in 1906 were Northwester, Geneva, McPherson, Economy, and Auburn, but most of these excepting Auburn were rather low in yield. In general the white wheats yield more grain, possess stronger straw, weigh a little less per measured bushel, and are slightly softer in the grain than the red varieties. Of 20 varieties of spring wheat grown in succession for 5 years, Red Fife ranked first with a yield of 33.5 bu. per acre, Pringle Champion second with 33.1 bu., and Saxonka third with 33 bu. In average yields for 14 years of macaroni wheats it was found that Wild Goose stood first with 39.7 bu., Medeah second with 35.4 bu., and Bart Tremenia third with 34.8 bu. per acre.

The leading varieties and their yields of rye, buckwheat, field beans, soy beans, cowpeas, flax, swedes, mangels, sugar beets, carrots, corn, millet, rape, kale, cabbage, etc., are also noted.

Cereal crop experiments, J. H. SHEPPERD and O. O. CHURCHILL (*North Dakota Sta. Bul. 75, pp. 283–336*).—The varietal study of grains in continuous progress since 1892 at this station, together with the plats on which the work was carried on, is described, and the results for the year 1906 are reported in tables and discussed.

Forty-five varieties of wheat were grown in 1906. With the exception of 1 variety there was only 3 days' difference between the maturity of the earliest and latest sorts. No. 1718, a new selection from the breeding nursery, was grown for the first time, and the fact that it lodged less than the rest, the straw being stiffer, is taken as showing the results of careful selection in the nursery. The varieties of different classes of wheat giving the highest average yields for 4 years were as follows: Blue stem, Select Blue Stem, 28.9 bu.; fife, Select Powers, 26.8 bu.; and durum, Black Don, 31.7 bu. per acre. Fourteen out of the 15 varieties of fife and blue stem giving the highest yields in 1906 came from the plant nursery of the station, and when the averages for 3 years are considered, 9 out of the 10 varieties giving the highest yields came from this nursery. The average for 7 years gives the durum wheats an advantage of 4.47 bu. per acre, as compared with the fife and blue stem varieties.

The following varieties of durum wheat have given the best results in the station trials and are recommended for North Dakota: Gharnovka U. S. No. 5646, Yellow Gharnovka U. S. No. 5642, Aronautka, Black Don U. S. No. 5645, Kubanka U. S. No. 5639, and Velvet Don U. S. No. 5644. The average yields of these varieties varied from 29.4 to 31.1 bu. per acre.

Fertilizer tests with wheat were made on land cropped for 20 years without fertilizing. The years 1903 to 1905, inclusive, showed a maximum increase in yield of 2.3 bu. of wheat per acre as apparently due to the applications. The most effective commercial fertilizer application gave only ½ bu. greater yield of wheat per acre than the use of well-rotted stable manure.

Different methods of soil preparation showed that spring disked corn ground gave as an average for 3 years 1.4 bu. more per acre than fall plowing. Fall plowed land gave 2.6 bu. more than spring plowing.

Wheat was drilled at the rate of 5 pk. per acre and 2 lbs. of rape was sown in addition. The rape did not interfere with harvesting, but sometimes delayed the curing of the bundles. The rape plants were strong and healthy, and when the wheat was cut and conditions were favorable a large quantity of good fall pasturage was produced.

The average comparative yields of different grains for 8 years were as follows: Oats 1,969 lbs., emmer 1,945 lbs., barley 1,877 lbs., durum wheat 1,835 lbs., and wheat 1,711 lbs. of grain per acre. Of 28 varieties of oats grown in

1906, Big Four ranked first in yield, with 58.1 bu. per acre. The heaviest oats was produced by English, which weighed 38 lbs. per bushel. In considering the average yields for 4 years it is shown that the late-maturing varieties were the most prolific.

The percentage of hull and the chemical composition of the whole oat, the hull, and the meat were determined, and the results secured apparently indicate that seasons favorable for a variety of oats decrease the percentage of hull, that some varieties give uniformly a higher percentage of meat, and that correlation seems to exist between the weight per bushel and the percentage of meat to hulls. As the rudimentary kernels decrease in size the percentage of hull up to a certain degree increases. It was also found that the variety weighing most per bushel is not necessarily the most valuable, and that the thickness of the hull seems to be somewhat hereditary.

In 1906 the yield of barley, owing to excess of rain, was very low. Among the varieties grown for 4 years Russian stands first, with an average yield of 41.7 bu. per acre, followed by common and Mansury, with 37.9 and 37.8 bu., respectively. Great Beardless gave the lowest average yield and McEwan Hulless the next lowest. The 6-rowed varieties led in yield in nearly every case. The 2-rowed varieties have weaker straw and are more easily affected by adverse conditions than the 6-rowed sorts.

The highest average yield of flax for 3 years, 14.4 bu. per acre, was secured from Select Russian. A mixture of durum wheat and oats produced 1,950 lbs. of grain per acre, while the grain grown separately produced only 42 lbs. more. The mixed crop produced the larger proportion of wheat. The crops grown separately produced 3.8 lbs. more digestible protein and 7.7 per cent more digestible ether-extract than the mixture, while the mixture contained 20.1 lbs. more digestible carbohydrates than the separate crops.

Dry farming in New Mexico, J. J. Vernon (*New Mexico Sta. Bul. 61, pp. 54, pls. 30*).—This bulletin defines dry farming, describes in detail the different practices it includes, gives reasons why fall seeding is preferable to spring seeding, discusses the importance and methods of storing and conserving the moisture, gives directions for the use of seed under dry farming conditions, and points out the results that may be expected.

The methods followed, as well as the results secured, in growing oats, sorghum, melons, squash, corn, wheat, alfalfa, spelt, potatoes, millet, barley, and beans by dry farming at Isador and in the vicinity of Las Vegas are presented.

Report of chemist [Field crops], A. L. Knisely (*Oregon Sta. Rpt. 1905, pp. 53–57*).—Experiments in steaming silage during the process of filling the silo seemed to indicate that corn fodder is the crop best adapted to steaming. Determinations of acidity showed that untreated silage varied in acidity from 1.01 to 1.94 per cent and averaged 1.58 per cent, while in the case of steamed silage the variation was from 0.30 to 0.88, with an average of 0.53 per cent.

Experiments to determine the effect of summer fallow were carried on in pot culture tests. The data reported show that in the fall of 1901, during the first month in which leaching occurred, the summer-fallow pots lost from 3 to 5 times as much nitrogen as those not summer-fallowed, and during succeeding years the summer-fallowed pots invariably lost considerably more nitrogen than those upon which crops were grown.

[Report of the] department of chemistry, F. W. Morse (*New Hampshire Sta. Bul. 129, pp. 239–242*).—Several analyses of silage crops and of oat samples representing the different weights per bushel of market oats are reported with brief comments.

The results with oats show that the light oats are inferior to the heavy grades in protein, fat, and nitrogen-free extract, while the fiber is higher. It is stated that this difference is due to the fact that the light oats contain about 10 per cent more hulls than the heavy oats. There was but little difference in the composition of the various heavy grades, and throughout the series of analyses the average fiber increased as the average weight of oats decreased.

Cost of filling silos, L. CARRIER (*U. S. Dept. Agr., Farmers' Bul. 292, pp. 15, figs. 3*).—Data were gathered on 31 farms, in Jefferson and Fond du Lac counties, Wisconsin, and Branch and Lewanee counties, Michigan, with reference to the number and arrangement of men and teams, machinery used, and the length of time taken in putting up silage. Measurements of the silos and other necessary information were also secured.

In estimating the cost of filling a silo a rate of 15 cts. an hour was made for men and the same for a team of 2 horses. Engine hire was rated at $4.50 per day, including the engineer, twine at 11½ cts. a pound, coal at $5 a ton, and gasoline at 13 cts. a gallon. Wear and tear on machinery and boarding the help was not taken into account. Ten hours were considered a day's work. The cost per ton of silage, as determined by this investigation, varied from 46 to 86 cts. on the different farms. The average yield per acre was 9.1 tons, and the average cost per ton of silage 64 cts. The average amount of silage cut daily per man was 4.9 tons, and the average cost per acre for putting the corn in the silo $5.98. The different factors which cause the cost per ton of silage to vary are pointed out and discussed.

Pressing hay, F. W. TAYLOR (*New Hampshire Sta. Bul. 129, pp. 252, 253*).—Data regarding the actual cost of pressing hay are reported. In April 48 tons were pressed at a cost of $1.40 per ton, in January 51 tons at a cost of $1.21, and in October 46 tons at a cost of $1.59.

Alfalfa or lucerne, C. L. NEWMAN (*South Carolina Sta. Bul. 127, pp. 16*).—This bulletin presents popular directions for the culture of alfalfa in South Carolina.

The subjects treated are the selection of soil, soil preparation and manuring, sowing the seed, inoculation with artificial cultures, water-extract from inoculated soil, inoculated soil, the treatment of the alfalfa field during the first and second year, the cutting and curing of alfalfa hay, and the uses and value of the crop.

Beans, L. C. CORBETT (*U. S. Dept. Agr., Farmers' Bul. 289, pp. 28, figs. 12*).—The different types of beans, including broad, kidney, Lima, dolichos, soy, scarlet runner, and velvet beans, together with cowpeas, are described and detailed information as to the culture of field and garden beans is given. The portion of the bulletin devoted to garden beans includes a discussion of the culture of pole and bush Lima beans. The diseases and insect enemies of the bean crop are briefly considered.

Bean culture, G. C. SEVEY (*New York: Orange Judd Co., 1907, pp. 130, figs. 33*).—This book devotes a chapter each to the following subjects with reference to bean culture: History and botany, conditions affecting growth, soil and fertilizers, beans as nitrogen gatherers, varieties and where they succeed, seed selection, breeding, and seed growing, insects and diseases with remedies, cultural methods, harvesting the crop, composition and feeding value, markets and marketing, and garden beans.

A study of Delaware seed corn, H. HAYWARD and H. S. JACKSON (*Delaware Sta. Bul. 77, pp. 16, pls. 10*).—Statistics of the Delaware corn crop are given, the importance of corn breeding, the method of carrying on the work, and the selection and storage of seed corn are discussed, and the results of germination tests of 150 samples of Delaware seed corn are reported.

Descriptions are given of a champion $150 prize ear of corn produced in Iowa and of the best ear in the 150 samples of seed corn collected in Delaware. While the 2 ears were similar in most respects, the Iowa ear had 4 more rows of kernels and nearly 30 per cent more kernels. It is stated that the measurements of the kernels of the 2 ears indicated that those of the Iowa ear were heavier than those of the Delaware ear, and that consequently it would shell more corn to the cob. The Iowa ear also had a greater circumference and the kernels were deeper than on the Delaware ear.

Germination tests were made of 10 ears from each of the 150 samples. Ten kernels from each ear were germinated in a specially constructed germinator and 5 kernels from each ear were germinated in sand. In the germinator 20 per cent of the ears showed imperfect germination and in sand 20.1 per cent. The percentage of ears unfit for seed as determined by these germination tests in both sand and cloth was 28.

From the study of the samples collected it is concluded that much of Delaware corn is susceptible to and worthy of improvement, and that by systematic selection the yields might be increased from 20 to 40 per cent.

The shrinkage of ear corn in cribs, A. N. HUME and O. D. CENTER (*Illinois Sta. Bul. 113, pp. 361-376*).—This bulletin shows that as an average for 10 years past the Chicago cash price for corn has been 3.8 cts. per bushel higher in May than in December, or 6.3 cts. if 5 lbs. less ear corn is taken for a bushel at this time than in December. In order to find out whether it would be more profitable to market corn as early as possible after husking or to hold it, shrinkage experiments were conducted and the increases in price necessary to compensate for the loss in weight were determined. Corn cribs were constructed at Urbana and Sibley in such a manner that they could be lowered to rest upon the platforms of large wagon scales and weighed. At Sibley a check experiment was made by weighing each wagon-load of corn as it was put into the crib and weighing out all the corn when the crib was emptied at the end of the trial.

The data given in tables showed that the first year the shrinkages of the 2 cribs at Urbana and Sibley varied between 12.3 and 19.8 per cent. December 6, 1901, 20,545 lbs. of corn were weighed into a crib at Sibley and weighed out again September 25, 1903, when the weight was found to be 18,690 lbs. The loss in this case was 1,855 lbs., or 9 per cent for the entire period of 22 months. In a second crib treated identically as the first the loss amounted to 9.2 per cent. In a stationary crib filled with corn early in November and emptied about a year later the weights in and out were respectively 19,850 lbs. and 17,280 lbs., representing a loss of 12.9 per cent for the year.

It was found that the amount of shrinkage of corn in cribs varies widely, and that the increase in price necessary to compensate for this shrinkage must consequently also be subject to the same variation. The present rate of decrease in the weight of corn up to September of each year runs from 12 to nearly 20 per cent in the 4 different trials, and an increase in price for September varying between 4.9 and 8.6 cts. per bushel is necessary to compensate for this loss in weight. The shrinkage for the third quarter of the year was noticeably greater than that of the second, the average difference being 8.7 per cent. The shrinkage from June to September averaged only 2.1 per cent, and by far the most noticeable shrinkage occurred during the months of April and May.

From observations on the shrinkage of corn during the second year of storage in cribs it was apparent that practically all moisture comes out of ear corn during the first year. In the one trial at Sibley the shrinkage was 19.6 per cent at the beginning of the second year and had increased to only about 20.5 per cent by the following September. It is concluded from these results that it is apparently safe to assume that old corn may be stored in cribs with very slight loss from shrinkage.

The weekly weights of the corn under test are tabulated to show to what extent the crib weights were influenced by the amount of moisture in the atmosphere, the weather conditions at or near the time of weighing being noted. The results secured at other experiment stations in this same line of work are briefly reviewed.

Cotton, A. LALIÈRE (*Le Coton. Paris: A. Challamel, 1906, pp. 250, pls. 24, figs. 15, dgms. 2, map 1*).—This book is divided into sections treating of the importance of raw cotton in the cotton industry, the culture of cotton, its preparation for commerce such as ginning and baling, the characters of the plant, the uses made of the fiber, seed, and other products, the principal cotton-growing countries, and the recent extension of cotton culture in various European dependencies. A list of works consulted by the author in the preparation of the book is given.

Experiments in the late planting of cotton to avoid boll weevil damage during 1906, C. W. FLYNN (*Louisiana Stas. Bul. 92, pp. 8*).—Experiments were conducted to determine whether general late planting in regions infested by the boll weevil could reduce the damage done by that insect.

One experiment was conducted in Vernon Parish, a field of 2½ acres surrounded by forest and about 2.5 miles from any other cotton field, being planted on June 6. On June 14, when the cotton was up to a stand, no boll weevils were observed, but on July 21, when the field had just commenced to square, 10.4 per cent of the squares were found infested, and on August 15, 63.6 per cent. An inspection of some of the nearest fields on July 21 showed that from 20.4 to 78 per cent of the squares were infested with the boll weevil, and a later inspection showed 92.5 to 99.2 per cent of the bolls infested. The experiment field, which in previous seasons produced about 1,200 lbs. of seed cotton per acre without fertilizer and in spite of the weevil, this year with late planting produced only 266 lbs., although well fertilized and well cultivated.

A second experiment at Merryville gave similar results, and the conclusion is drawn that late planting will not serve to solve the boll weevil problem.

Preliminary report on distance experiments with potatoes, M. STEFANSSON (*Norges Landbr. Hoiskoles Akervekst. Aarsber., 1905-6, pp. 55-60*).—Experiments were conducted with 83 varieties of potatoes on 209 plats. The distance between rows was 60 cm. and that between the plants in the rows 20, 30, and 40 cm. The largest yields were in most cases secured by planting 20 cm. apart. The greater distances are considered advantageous only when heavy yields may be expected.—F. W. WOLL.

The nonsaccharine sorghums, C. W. WARBURTON (*U. S. Dept. Agr., Farmers' Bul. 288, pp. 28, figs. 9*).—A classification of the sorghums is given, together with historical notes on their introduction and culture in this country. The characteristics of the different varieties are pointed out and complete directions are given for the growing of these crops as well as their utilization for fodder, hay, pasture, silage, and soiling.

The 3 distinct classes of sorghums are the broom corns, the saccharine, and the nonsaccharine sorghums. The last named may be divided into 2 groups, Kafir corn and the duras. Kafir corn is stocky, leafy, with erect heads, while the duras usually grow taller, are less leafy, and often have the heads goosenecked. The nonsaccharine sorghums are of great value in semiarid sections. They grow on any good soil, but do best on a sandy loam and are remarkably resistant to drouth and alkali, although this resistance is not uniform for the different varieties. The poor physical condition in which they leave the soil may be overcome by proper tillage. Yields per acre of 25 to 50 bu. of grain and 2 to 5 tons of dry fodder is the usual crop. The grain and fodder are about equal in feeding value to corn, but are slightly less digestible.

It is further stated that the earliness, quality, and yield of the crop may be greatly influenced by careful selection of the seed.

Progress of the beet-sugar industry in the United States in 1906, C. F. SAYLOR (*U. S. Dept. Agr. Rpt. 84, pp. 135.*)—A general review of the beet-sugar industry for the year is given, and discussions on some important features and benefits of sugar-beet culture, the promotion of the sugar industry, new features relating to factory operations, and improved implements and devices for the benefit of beet growers are presented, together with the climatic conditions and farm and factory results by States for 1906, and statistics of the sugar industry in the United States and the world at large. The work with sugar beets of the Bureau of Plant Industry of this Department, comprising studies of the effects of fertilizers, of culture methods, methods of siloing, sugar-beet diseases, single-germ beet seed, breeding of strains for early maturity and for dry and alkali lands, methods of improving yield and quality, production and improvement of commercial beet seed, and the extension of the sugar beet area, is also briefly described.

The total number of factories operating in 1906 was 63. A total of 376,074 acres of beets, averaging a yield of 11.26 tons per acre, was harvested. The total quantity of beets worked was 4,236,112 tons, producing 483,612 tons of sugar. The average sugar in the beets was 14.9 per cent, the average purity 82.2 per cent, the average length of the campaign 105 days, and the estimated average extraction of sugar 11.42 per cent. The increase in acreage harvested over 1905 was more than 22 per cent, and the increase in the average yield of beets per acre as compared with that year was 23¼ per cent. The highest average yield per acre by States was produced in Utah, being 15.88 tons, and the next highest in Colorado, 13.41 tons.

The process of drying beets or cossettes prior to extracting their juices by diffusion, denatured alcohol in its relation to the sugar industry, and the development of conditions and prospects of extending the beet-growing industry are discussed. With reference to the drying of beets, it is stated that the practicability of the process has not as yet been established, but that enough of importance has been ascertained by experimentation to make it worthy of further tests. If practicable the process promises a reduction in the cost of beet sugar.

Under the direction of the Bureau of Plant Industry, 278 acres of American-grown seed yielded 14.32 tons per acre, with an average sugar content of 14.9 per cent or 4,267 lbs. of sugar per acre, while imported seed gave an average yield of 12.14 tons per acre, with a sugar content of 15.1 per cent, or 3,666 lbs. of sugar per acre. Twenty acres of seed beets, all of which analyzed 22 per cent or more of sugar, were grown at Fairfield, Wash., during the year. About 15,000 lbs. of seed were secured from these beets.

Sugar beet industry, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 69–71*).—The results of variety tests with sugar beets indicated that Rubensamen and Improved Imperial are equal in purity to Kleinwanzleben and contain slightly more sugar. Distance experiments conducted for 5 years showed a regular difference in the weight of the beets as the distance between the rows increased from 12 to 28 in. There was, however, no corresponding decrease in the percentage of solids and sugar or in the purity. It is believed that the best general results are obtained in rows placed as closely as possible without seriously inconveniencing the work of cultivation.

The chemistry of the sugar cane and its products in Louisiana, C. A. BROWNE, Jr., and R. E. BLOUIN (*Louisiana Stas. Bul. 91, pp. 103*).—This bulletin presents a summary of data collected during the past few years by the Louisiana Sugar Experiment Station.

The composition of the leaves, stalks, roots, and seeds of sugar cane and of the ash of the plant is shown in tables. The composition of the ash was found to vary widely with the variety of cane, type of soil, and manner of fertilization. It is stated that sugar cane contains only a very small quantity of fat or oil, mostly in the interior tissues, while the wax is found entirely upon the outer surface and constitutes about 1 per cent of the rind. The average total nitrogen of many analyses of sugar cane at the station was only about 0.05 per cent. An analysis of several stalks of Louisiana Purple cane showed that the nitrogen, although only a small quantity, is distributed among a large number of different bodies. Attention is also called to Beeson's work, which shows a greater localization of albuminoids in the nodes and of amids in the internodes. The rind, the pith, and the fibrovascular bundles, among which the fiber of the plant is distributed, showed a certain regularity with reference to all constituents except ash, the fibrovascular bundles standing intermediary between the rind and the pith. The rind showed the maximum and the pith the minimum of lignification The statement is made that the cellulose obtained from the cane resembles that of cornstalks. Notes are given on the 3 principal sugars, sucrose, dextrose, and levulose, and on the pectins or gums, and the acids.

In the study of the physiology of the growth and ripening of the sugar cane, analyses of the juice taken from the young cane at night and in the morning indicated a large decrease in the amount of sucrose during the night and a corresponding increase in the amount of reducing sugars. In the top joints, where growth is most intense, the disparity between sucrose and reducing sugars was greatest. In the middle joints, where the process of growth is being suspended, the reducing sugars are being reconverted to sucrose, which is then stored up in the pith cells as reserve juice. The same takes place in the bottom joints, only to a greater degree. Similar phenomena were observed in an analytical study of D 74 and D 95 canes at various intervals between the middle of July and the middle of October. A regular increase in the percentage of fiber and sucrose took place, although no fixed ratio between these 2 substances could be established. The ash, acids, nitrogenous bodies, and gums all showed a decrease as the cane matured. The reducing sugars, dextrose and levulose in the green tops and joints of the cane, and also in the stalks of very young canes, are present in very nearly equal amounts, but in the riper joints this relation no longer exists. The disparity in the content of dextrose and levulose increases with maturity until finally the levulose may nearly disappear.

In discussing the physiological rôle of the enzyms of the sugar cane, attention is called to the gradual falling off in sucrose content of sugar cane windrowed for any length of time, and it is shown by analyses made in 1893 that, if the green tops of the cane are removed at the time of cutting, the loss of sucrose is much less evident. In the windrowed cane from which the tops were not removed the loss of sucrose due to spontaneous inversion was very evident, and this is attributed very largely to the diffusion of the inverting enzym from the green tops into the stalk. The inversion of sucrose causes an increase in the glucose content. These results are taken as showing conclusively that the vital processes go on even after the cane is cut. The darkening in color of the juice immediately after extraction and also within the body of the cane is described as due to an enzym belonging to the class of oxydases. Other phenomena in which the action of enzyms plays a part are also discussed.

The results for 1903 show but little variation in the sucrose and glucose content and the purity of the cane up to the middle of September. After this date the canes of 1903 increased considerably faster in sucrose and at the end of the season showed an excess of 3.86 per cent over the sucrose content in the case of 1904. The climatic conditions for 1903 retarded the growth but hastened maturity, while those of 1904 promoted growth and retarded ripening. The variety also exerts an influence upon the composition. It was found, for instance, that the ash content in the juice of D 74 was 0.48 per cent, while D 95 stood second, with 0.41 per cent, Purple third with 0.40 per cent, and Striped fourth with 0.34 per cent, and this was also their relative position in sucrose content, while as regards reducing sugars the order was the reverse. It is stated that these results indicate that D 74 is the most vigorous feeder and has the greatest powers of assimilation and conversion. The conditions of cultivation also influence composition.

A comparison of many analyses of leading varieties at Audubon Park shows that stubble cane contains from 10 to 20 per cent less ash and over 50 per cent less nitrogen than plant canes, and that the deficiency of nitrogenous ingredients in stubble canes falls most largely upon the reserve supply of nitrogen or the amids, this being due to the greater nitrogen hunger of the stubble canes.

That soil and fertilization have their effect upon composition is shown by the fact that canes from the lower coast of the State sometimes contain 4 times the amount of chlorids found in canes raised above New Orleans.

Numerous analyses are reported in connection with the study of the composition of sugar-cane juice and the methods of extraction. According to the averages of 10 stalks of plant cane cut and topped according to the methods usually followed in Louisiana, the solids not sugar in the juice increase towards the upper portion of the stalk, taking a sudden jump in the last 2 or 3 joints. In some cases the purity of the juice in the upper joints is less than one-half that from the butt of the cane. Analyses of juices obtained by the mill and by the diffusion battery show that the percentage of mechanical impurities, such as gums, etc., is much higher in the mill juices. The hot water used in diffusion, on the one hand, coagulated a larger amount of albuminoid matter which was held back in the diffusion chips, but on the other effected the solution of a larger amount of amids and mineral matter.

The results of experiments upon alkaline and acid clarifications led to the suggestion that for Louisiana conditions, where the juices usually contain a high percentage of reducing sugar as compared with tropical countries, a carefully conducted sulphitation gives the most satisfactory results from the point of economy, as well as from the favorable output of sugar.

A schematic tabulation of yields and compositions of sugar-house products is given, and the effects of fermentation upon the composition of sugar-cane products is discussed.

Tobacco, W. H. SCHERFFIUS (*Kentucky Sta. Bul. 129, pp. 15, pls. 15*).—This bulletin discusses the selection of seed plants and care of seed, improved methods of handling tobacco, and the eliminating of undesirable varieties.

A hybrid obtained at the station by crossing Standup Burley with Sumatra was not very promising the first year, but showed a decided improvement in the second crop. This cross was made to develop a cigar wrapper by introducing into the Standup Burley some Sumatra blood.

Experiments are in progress at the station in a specially constructed drying shed to ascertain at what temperature and humidity Burley tobacco may be cured free from house-burn. In a compartment in which the tobacco was badly affected with house-burn the application of 10° of dry heat for an hour or more completely stopped the trouble. In the chambers where heat was continually applied no house-burn developed. Where sufficient heat was applied to increase the temperature from 100° to 120° F. tobacco cured with a greenish east, but this tendency was overcome to some extent by applying moisture at the same time.

In the work of eliminating undesirable varieties it was found that with 11 sorts of White Burley grown under uniform conditions the estimated yields varied from 1,479 lbs. to 2,137 lbs. per acre, or a difference of 658 lbs. per acre between the minimum and maximum yields.

The regulations for the culture of tobacco in France, A. MURAT (*La Réglementation de la Culture du Tabac en France. Toulouse: Univ. Toulouse, 1906, pp. 151*).—This thesis traces the history of tobacco culture in France from its beginning to the present day, and brings together the different laws and regulations with reference to its culture which have been enforced from time to time A bibliography of the official documents and of general and special works on this subject, which have been consulted in the preparation of the thesis, is included.

Modern plant-breeding methods, with especial reference to the improvement of wheat and barley, R. H. BIFFEN (*Sci. Prog. Twentieth Cent., 1 (1907), No. 4, pp. 702-722*).—This paper contains an historical review of plant breeding, discusses the hybridization of wheats and barleys with reference to Mendel's law, and considers the subject of breeding disease-resistant plants.

HORTICULTURE.

[**Horticultural investigations in Alaska**], C. C. GEORGESON ET AL. (*Alaska Stas. Rpt. 1906, pp. 10-14, 23-38, 46, 47, 50, 51, 53-66, pls. 3*). Notes are given of the results secured at the Alaska experiment stations located at Sitka, Copper Center, Rampart, and Kenai in variety and cultural tests of various vegetables, orchard and small fruits, and flowers Large quantities of seed, fruit trees, and bushes have been distributed to various parts of the territory, and the reports are here given from several of the cooperators with regard to the trial and behavior of these seeds and plants.

It is believed that the native crab apple (*Pyrus rivularis*) may have a possible value as a stock for dwarf trees. Dwarf trees are considered to be superior to standard trees in this region since they bear earlier, can be more easily protected when necessary, admit of closer planting, and are less exposed to the wind. A number of varieties of apples have been grafted on this species by various methods. The crown grafting appears thus far to be the most successful, while top-worked trees do fairly well.

An attempt is being made to develop varieties of strawberries and raspberries adapted to the climate by cross-fertilizing cultivated varieties with wild native species. Several species of currants are also found native in Alaska and are being brought under cultivation. Attempts to cultivate the eastern cranberry have proved unsuccessful and the experiment has been dropped. The so-called Alaska cranberry (*Vaccinium vitisidæa*) is said to produce a small but very delicious fruit, no larger than the red currant. It grows on old stumps and decayed logs and on little knolls just out of the standing water. Plantings of this berry have been made at the station.

[**Report of**] **the professor of horticulture,** H. L. HUTT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 138-149, figs. 5*).—An outline is given of work conducted for the year with orchard and small fruits, vegetables, and flowers, including data on results secured from a trial of a large number of plants as orchard cover crops, fruit variety tests, and notes on plant breeding experiments.

In the investigations with tree fruits, commenced about 10 years ago, apples appear to have stood the adverse conditions better than most of the other fruits, all of which suffered more or less in the severe winter of 1903–4. Notes are given on the varieties of apples, pears, plums, and cherries being grown in the orchard. Pears are considered more or less a failure, and only the hardiest varieties of cherries of the sour type have withstood the climate.

An extensive variety test was conducted with raspberries, blackberries, currants, gooseberries, and strawberries. With red raspberries Marlboro is considered the best early variety in the trials thus far, and Cuthbert the best late variety. Herbert, a new variety originated with R. B. Whyte, is said to rank first among the red varieties this year; Columbian is considered the best purple variety; Older and Smith Giant the best blacks, and Golden Queen the best yellow variety. In regard to blackberries, the conclusion is reached, after 10 or 12 years' testing of 23 varieties, that they can not be satisfactorily grown. Eldorado and Agawam have proved the hardiest. Of the currants, the White Grape has usually been the most productive of the 46 varieties grown. During the past season Climax, a new black variety, gave the largest yield. The other leading varieties of currants are similar to those previously noted (E. S. R., 17, p. 862). Forty-five varieties of gooseberries were tested, of which 36 have fruited. The most productive varieties have been those of American origin, such as Pearl and Downing. Lady Leicester, a new variety, has given the heaviest crop for the past 3 years. The fruit, however, is small and is not recommended for general planting. Of the large fruit varieties, Red Jacket and Whitesmith are considered the best, although not nearly so productive as Pearl or Downing. Among the strawberries, of which over 400 varieties have been carefully tested, the following are recommended to give a constant supply of berries from early to late season: Early varieties, Splendid, Warfield, and Haverland; midseason, Williams, Ruby, Clyde, and Parson Beauty; late, Buster. The last variety, although a heavy yielder and valued for home use or market, is considered undesirable for canning on account of its light color.

The plant-breeding work of previous years has been continued and a great number of crosses of various kinds have been made. A large number of berries were produced as the result of using pollen of Falstaff, a European raspberry, on Herbert and Cuthbert raspberries, from which it is hoped to obtain the quality and size of the European berry and the hardiness of the native species. Columbian was successfully crossed with the strawberry-raspberry. An attempt is being made to improve the common chokecherry by the selection of pits from large fruit found to be much less astringent than the average.

Practical treatise on horticulture for Northern Africa, L. GUILLOCHON (*Traité Pratique d'Horticulture pour le Nord de l'Afrique. Tunis: S. Père & Sons, 1907, pp. III + 490, figs. 30*).—This work is introduced with some general considerations on garden making, necessary equipment and tools, and various methods of propagation. Part 1 deals with the vegetable garden, the cultivated species being arranged in alphabetical order and classed as herbaceous, bulb, fruit, and seed crops. Part 2 treats of the cultivation of fruit trees, including the various phases from the orchard nursery to the storage of the fruit, and concludes with a list of species suitable for cultivation in Algeria and Tunis. Part 3 discusses ornamental arboriculture, with suggestions on the subject of reafforestation and various forms of planting. Part 4 is devoted to ornamental and commercial floriculture, all the varieties of flowers suited for Northern Africa being considered. Part 5 treats of the cultivation of the agave fiber plants. The book is concluded with a working schedule for each month of the year.

Ringing herbaceous plants, U. P. Hedrick, O. M. Taylor, and R. Wellington (*New York State Sta. Bul. 288, pp. 193–209, figs. 4*).—This bulletin reports experiments in ringing 2 herbaceous plants, the tomato and chrysanthemum, which were selected because their product and manner of growth should show to advantage the effects of ringing.

Some general considerations are given on the objects of ringing woody plants and the theory upon which ringing is founded, and the present experiments with herbaceous plants are described and discussed in detail.

The tomatoes were trained to a single stem and were ringed in the winter of 1905–6. The first group was ringed when the second cluster of fruits had set, and the second group when the fourth cluster had set. The plants in the third group were unringed. The ringing consisted of removing a ⅝-in. strip of bark, cutting through to the woody tissue. As the result of this experiment it was found that the height of the stems were not affected, but there was a tendency toward the thickening of the whole stem above the wound. Ringing had no effect upon the time of maturity, color, or flavor of the fruit. The average number of fruits per plant was reduced 18 per cent by the first ringing and 10 per cent by the second ringing, and the average loss in weight per plant attributed to the first ringing was 16 per cent, and to the second ringing 12 per cent. During the first ringing there appears to have been a gain of 0.06 oz. in the average fruit, although in the second ringing a loss of 0.05 oz. is noted. The foliage of the ringed plants was more or less abnormal, and the roots were less developed, fewer in number, and smaller in size.

Several varieties of chrysanthemums were treated in the same manner in the autumn of 1906. The first group was ringed just as the buds appeared, and the second when the buds were one-third grown, the interval between ringings being about 2 weeks. In this case ringing decreased the height of the plant. The first ringing appeared to hinder the opening of the buds in all the varieties except one, and the second ringing to slightly hasten the maturity of all except one. The size of the blossoms of all varieties was reduced, and the earlier the ringing the greater the injury. Ringed plants produced almost no suckers. The foliage and roots of the plants suffered in the same manner as with the tomatoes.

From the results secured, the authors conclude that it is very doubtful if ringing can be made beneficial to herbaceous plants, the loss to the plant being great, with little or no compensating gain.

Ringing detrimental to tomatoes and chrysanthemums, F. H. Hall (*New York State Sta. Bul. 288, popular ed., pp. 4*).—A popular edition of the above.

In order to have artichokes the greater part of the year, R. Beziat (*Jardin, 21 (1907), No. 482, pp. 90–92*).—This article contains directions for the culture of the globe artichoke in various regions of France, together with varieties recommended for each.

Some attempts in the grafting of Solanums, E. Griffon (*Bul. Soc. Bot. France, 53 (1906), No. 9, pp. 699–704, pl. 1*).—In order to make personal observations as to the influence, if any, of the stock on the graft and vice versa, the author made several grafts, including the potato on the tomato, the tomato on the potato, the tomato on the egg-plant, the egg-plant on the tomato, and *Solanum laciniatum* on *S. ovigerum*. Stocks of the parent plants were grown side by side with the grafted plants, under the same condition of soil and culture.

As a result of these experiments the author concludes that no variations took place either in method of growth, form, or shape which would indicate any influence of the stock on the graft, or reciprocally, but that the variations which were noted occurred just as frequently on ungrafted plants and may be attributed to the same causes.

Marketing fruit and truck crops, W. N. Hutt (*Maryland Sta. Bul. 116, pp. 211–257, figs. 39*).—This bulletin contains information with regard to the grading, packing, and marketing of a large variety of fruit and truck crops, and is introduced by a discussion in regard to the value of standard packages, brands, and trade-marks, and the relations of the railroads, commission men, and fruit dealers to the grower.

Accounts are also given of the New York fruit exchange and a few types of cooperative fruit-shipping associations or exchanges. The text is accompanied by several figures illustrating various styles of fruit packages, etc.

Orchard management, C. I. Lewis and W. H. Wicks (*Oregon Sta. Bul. 93, pp. 47, figs. 28*).—This bulletin contains popular directions for growing the more important kinds of orchard fruits, including a discussion of the location and site, soil, drainage, methods of cultivation, use of cover crops and fertilizers, irrigation, pruning, thinning, spraying, pollination, etc.

The State is divided into 5 horticultural districts, and lists are given of apples, pears, cherries, plums, prunes, peaches, grapes, strawberries, raspberries, blackberries, currants, and gooseberries adapted for planting in the several districts.

The apple from orchard to market, C. I. Lewis (*Oregon Sta. Bul. 94, pp. 48, figs. 34*).—This bulletin contains popular directions for harvesting, grading, packing, and marketing fruit, together with suggestions for the formation of cooperative associations. In an appendix by E. H. Shepard the various features of the Hood River apple growers' union are described, including the articles of incorporation and by-laws, together with advice and special directions to growers and packers. Extracts are also given from the Canadian fruit marks act of 1901. The text is well illustrated.

The home apple orchard, M. S. McElroy (*Farming, 3 (1907), No. 4, pp. 140, 141, figs. 7*).—Directions are given for the planting and subsequent care of a home apple orchard, together with a list of varieties recommended for planting in different sections of the United States.

The effect of wood ashes and acid phosphate on the yield and color of apples, U. P. Hedrick (*New York State Sta. Bul. 289, pp. 211–235, dgm. 1*).—This bulletin contains an account of an experiment conducted by S. A. Beach in the station orchard from 1893 to 1904, inclusive, regarding the value of potash, phosphoric acid, and lime as found in wood ashes and acid phosphate for fertilizing apple orchards.

The experiment was originally planned to determine the effect of wood ashes on the scab fungus in the apple, as well as the value of the ashes as a fertilizer. At the end of 5 years it was determined that the wood ashes had no material effect on the scab fungus, and this feature of the experiment was dropped. A preliminary report of the experiment as published in 1897 has been noted (E. S. R., 10, p. 452).

The present account is based on the above report, together with subsequent data. In 1898 the test of wood ashes was supplemented by one of acid phosphate, and the two experiments were conducted through 1904. The trees, of which there were 94 in the test, were 43 years old at the beginning of the experiment, and included the following varieties: Baldwin, Fall Pippin, Rhode Island Greening, Roxbury, and Northern Spy. The orchard was divided into 8 plats, 4 treated and 4 untreated. Wood ashes were applied at the rate of 100 lbs. per tree, or 4,800 lbs. per acre, to which was added during the last 7 years acid phosphate at the rate of 8½ lbs per tree, or 408 lbs. per acre. From these applications it is calculated that the trees were supplied each year with

169 lbs. per acre of actual potash, 72 lbs. of phosphoric acid from the ashes, as well as 57 lbs. from the acid phosphate, and lime at the rate of 32 lbs. per tree, or 1,536 lbs. per acre.

The effect of the fertilizer was measured by the yield and color of the fruit. Although there was a slight annual average increase in yield per tree on the treated plats for the several varieties, with the exception of Northern Spy, the results are considered practically negative from a financial standpoint, since the calculated gain per year on 5 acres is only $24.50, or not more than enough to pay for handling the fertilizers. It is also noted that both the treated and untreated plats increased markedly in yield from 1893 to 1904. By way of explanation it is stated that prior to 1893 the orchard was in sod, but during the experiment was kept under cultivation and grew more productive. The results as to the color of fruit appeared to lack uniformity and "were not decided enough in a sufficient number of the 12 seasons to enable us to state that the fertilizers applied improved the color of the apples." The influence on color appeared most marked in seasons with climatic conditions unfavorable to the development of the fruit.

With regard to the practical application of the results obtained in this experiment, it is believed that fruit growers should not apply manures in quantity until good evidence has been obtained as to what food elements, if any, are wanting in the soil. This should be ascertained by fertilizer tests conducted directly in the orchard in question. A brief plan adapted from a fertilizer experiment under way for the past 10 years in a young apple orchard on the station grounds is given to be used by the grower in determining to a certain extent what fertilizer his orchard needs.

Unprofitable orchard fertilizing, F. H. Hall (*New York State Sta. Bul. 289, popular ed., pp. 8, fig. 1*).—A popular edition of the above.

Evaporation of apples, H. P. Gould (*U. S. Dept. Agr., Farmers' Bul. 291, pp. 38, figs. 16*).—This bulletin contains an account of the author's studies with regard to the evaporation of apples, including a description of several types of evaporators adaptable for home and commercial purposes, various evaporator appliances and conveniences, methods of preparing and drying the fruit, and information in relation to the grading, marketing, and storing of the product. The subject-matter is well illustrated.

The cherry, F. Peneveyre (*Chron. Agr. Vaud, 20 (1907), Nos. 2, pp. 29–32; 3, pp. 53–57; 4, pp. 74–80; 7, pp. 146–153; 8, pp. 157–162, figs. 16*).—This is a short treatise on the cultivation of cherries, including a botanical description of the genus, methods of propagation, nursery practices, training, selection of site and soil, planting distances and operations, fertilizers, various styles of planting, and subsequent care.

Fertilizers on prune trees, A. L. Knisely (*Oregon Sta. Rpt. 1905, pp. 57–59*).—Fertilizer experiments were conducted on a 5-acre Italian prune orchard during the 4 years from 1901 to 1904, inclusive. The soil was classed as a loam and was similar to many other prune orchard soils. Alternate rows throughout the entire orchard were treated with nitrate of soda, Thomas slag, muriate of potash, and sulphate of potash, either alone or variously combined.

The results secured in the last 3 years of the experiment are presented in tabular form, showing the average yield of fresh prunes per tree. No marked effects from the different combinations of fertilizers were noticed during the growing season, and the results were not decided enough to indicate a very profitable use of fertilizers.

Further experiments are to be made in order to ascertain whether the quality of the fruit has been affected by the fertilizers, in which special attention will be given to the sugar and acidity in the ripe fruit.

Notes on the Tunis varieties of olives, R. MARCILLE (*Bul. Dir. Agr. et Com. [Tunis], 2 (1906), No. 41, pp. 511–527*).—In 1900 olive plantations were established at the colonial school of agriculture and at the experimental garden of Tunis. At the present time over 80 varieties have been brought together, many of which have fruited for the past 2 seasons.

In this article the observations which have been made on these plantations are presented, including a study of the relative value of the varieties of olives utilized for pickling, the value and the yield of those used in the extraction of oil, and the quality of the oil derived from Tunis olives.

The article concludes with a discussion of the methods of propagating the olive. The author is of the opinion that propagation by seed brings about the best results. It is stated that the seed-grown trees are much hardier, more resistant to disease, and more productive than plants propagated from cuttings. The principal disadvantages of seed-grown plants are the increased length of time before they come into bearing, and the necessity of grafting.

Work conducted at the government's American grape nurseries at Nicastro and Palmi for the three years 1904–1906 (*Bol. Uffic. Min. Agr., Indus. e Com. [Rome], 2 (1907), No. 1, pp. 34–44*).—This is a summary, together with the more important data, relative to work conducted at the government nurseries of Nicastro and Palmi in the testing and distribution of American grapes for the 3 years 1904–1906.

During this period a total of 813,325 cuttings and grafted plants were distributed from the Nicastro nursery, and 890,360 from the nursery at Palmi Tables are given showing the species and varieities of stock plants grown, the kind of soil, and notes on vegetative conditions. The relative merits of the different species, as to their resistance, adaptation, and value as stocks for European grapes are also discussed

Tables are given showing the hybrids grown at both nurseries, the kind of soil, the number of plants of each variety, and observations as to vigor, fruitfulness, etc. The article also includes a discussion of the Roncet disease, and notes on the school of grafting and the demonstration farm.

Selection and preparation of vine cuttings, F. T. BIOLETTI (*California Sta. Circ. 26, pp. 7*). In this circular the author discusses the importance of a proper choice of cuttings as a factor in determining the profitableness of vineyards, and makes popular suggestions regarding the means of obtaining cuttings capable of growing into strong, heavy-bearing vines.

Among the phases considered are the choice of locality, vineyard, vine, and part of vine in selecting cuttings, together with the form and length of cutting, and methods of conservation.

Concerning the bagging of grapes, J. B. PILLOT (*Jardin, 21 (1907), No. 483, pp. 107, 108*).—This is an account of the author's experiments in the bagging of grapes conducted at Nancy, France.

The principal advantage noted is that many of the finer varieties of grapes which will not mature their fruit well in the open air in the cooler regions in the eastern part of France, will yield satisfactorily when the fruit is bagged. While he found a number of dried and scalded grapes among those included in his bagging experiments, this is attributed principally to the lack of ventilation.

In the author's spraying experiments, the ordinary method of spraying grapevines with a solution of copper sulphate appeared ineffective as far as the fruit was concerned, although it was found effective in preserving a healthy foliage. Experiments in the dusting of grapes with dry copper sulphate were carried on for a period of 2 years. It is stated that the fruit matured well and gave abundant yields, while with the check plats, which were sprayed in the ordinary manner, the grapes suffered severely from mildew.

Tea culture, with notes on the production of indigo in Java, W. Detmer (*Botanische und landwirtschaftliche Studien auf Java. Jena: G. Fischer, 1907, pp. 44–51*).—A brief account is given of the cultivation of tea in Java, including the planting, fertilizing, harvesting, and preparation for market, together with a description of the extraction and fermentation of indigo in Java, and a discussion as to the advisability of growing indigo as a cultivated crop in that country. Although the price of artificial indigo is much lower than that of the natural product, the author is of the opinion that this crop might be used as a combination crop with tea, since after the extraction of the indigo the large amount of plant material remaining can be used as a fertilizer for the tea.

Notes on palms and the exotic species cultivated in Egypt, A. d'Abaza (*Alexandria Hort. Soc. Bul. 2, 1907, pp. 1–46*).—A botanical description and classification of palms, together with a descriptive list of exotic species growing in Egypt and a list of those recommended for introduction into that country.

FORESTRY.

Improvement of the woodlot, H. D. House (*South Carolina Sta. Bul. 129, pp. 14, figs. 2*).—This bulletin is presented with a view to interesting the land owners and farmers of western South Carolina in the improvement of the depleted forest conditions of that region.

The present work deals largely with a discussion of surveys made of 2 tracts of woodland near Clemson College, including a description of the areas and tabulated data with reference to their composition and size of the timber, and the conditions found in these areas which will work favorably and unfavorably on the value of the tracts.

Suggestions are given for the care and improvement of the forest and woodlot, together with a list of valuable native trees for planting on different types of soil in western South Carolina. *Catalpa speciosa* is considered one of the most valuable for extensive planting in low grounds, as it has a rapid growth and possesses superior qualities for posts and ties.

Forest revenues and forest conservation, J. F. Clarke (*Canad. Forestry Jour., 3 (1907), No. 1, pp. 19–30*).—In this address, delivered at the forestry convention, Vancouver, September, 1906, the author discusses the disastrous effects of the present methods of lumbering on the conservation of Canadian forests, and points out the salient features and one notable omission of the present system of agreements between sellers and lumbermen, with special reference to their influence on the character of the logging which they authorize and should, but do not, control.

The author states, in substance, that the present form of agreement existing between sellers and lumbermen places a premium on the destruction of lumber, and that the solution of the problem of conservation will be reached when a system of sale of public timber is evolved and made effective by which the State and the lumbermen become partners, with mutual profit, in the work of renewing the forests by the act of logging the matured trees.

A table is given showing the annual ground-rent payment per square mile for the different provinces and on dominion lands, with sums computed at 6 per cent interest compounded annually, to which these annual payments amount for different periods of from 30 to 100 years. Particular attention is directed to the manner in which the tax bill runs up the longer the time between loggings. Where the lumberman is the forester the influence of a ground rent is said to be towards earlier utilization and clean cutting, with the abandonment of the land after the timber is removed.

With respect to cutting regulations it is stated that the dearth of any effective measures to control the cutting on Canadian limits is nothing short of a disaster alike to the future lumbering industry and to the future forest revenue.

In conclusion the author submits an outline of a method of disposing of crown timber which, it is believed, will offer a simple, practical, and business-like solution of the problem.

Annual of streams and forests for 1906 (*Ann. Eaux et Forêts, 45 (1906), pp. 370*).– This contains tables complete to January 1, 1906, with reference to the personnel of the forest administrations in France and Algeria, and lists of pro motions from the National School of Streams and Forests and from the secondary school of technical and professional education for foresters, together with numerous statistics of general interest.

Training and examination of private forest officials in Germany, M. LINCKE (*Ausbildung und Prüfung von Privatforstbeamten in Deutchland. Neudamm: J. Neumann, 1906, pp. VIII + 180*).—This is a manual of information for the private forest officials of Germany with respect to examinations, positions, appointments, transfers, etc., and is also intended as a guide for candidates for the profession of forestry.

[Report of] the lecturer in forestry, E. J. ZAVITZ (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 194–200, figs. 6*).—This is an outline of the forestry work conducted during the year in the college woodlots and nurseries, including notes on the species of trees grown. A brief account is also given of cooperative planting experiments undertaken during the past season. About 20 plantations in all were established during the year in several counties of the province, in which about 80,000 plants were used.

Report of the forestry branch, 1906, R. D. HAY (*Rpt. Forestry Branch N. S. Wales, 1906, pp. 9, figs. 8*).—This is a report as to the forest areas, administration, and sylvicultural work, together with a financial statement to June 30, 1906. The area included in forest reserves was 7,749,579 acres. During the year 184 sets of specimens, comprising 4,420 kinds of timber, were prepared by the Museum of Economic Forestry and issued in advertisement of the timbers of the state. The state forest nursery now contains a considerable variety and stock of plants in all stages of growth, amounting to about 100,000. Plants amounting to 49,885 were distributed during the year.

The revenue for the year was £42,738 1s. 7d., the expenditures £16,638 18s. 10d., leaving a surplus of £26,099 2s. 9d. During the year 339 sawmills were in operation, which employed 3,806 people. The number of persons directly employed in connection with the timber industry was 16,800. Satisfactory results are being obtained in the eradication of the prickly pear. A table is given showing by States the extent of forest resources of the Australian continent. Australia has an acreage of 1 wooded acre for approximately every 18, and 1 acre in every 109, or about 0.9 per cent of the total area of the continent, is reserved for forestry.

This report is accompanied by the report of the government botanist on forestry work, consisting of an outline of the work conducted during the year, and by several illustrations of large timber trees and lumber operations in New South Wales.

Western Australian timber tests, 1906, G. A. JULIUS (*Perth: Govt., 1906, pp. 36, pls. 72*).—This is a report of the results of over 16,000 tests upon the physical characteristics of the hardwoods of Western Australia, including tests in cross-bending, tension, end and cross compression, shearing, hardness, effect of repeated blows, moisture, the holding power of the various timbers upon railway dog spikes both with green and dry timbers, with spikes both newly driven and those remaining in sleepers for a varying number of years, chemical tests to determine the nature of the sap present in the various timbers and its effect upon metals, and investigations to determine the resistance of these timbers to dry rot, white ants, etc.

In the moisture tests each section was cut immediately after the completion of the physical test and the moisture condition determined. The position of the tree from which a specimen was cut was taken into consideration, and a complete record of the sections used for all tests was kept with reference to the direction of holding relative to the annual rings and radial lines.

The data obtained from the tests are summarized upon numerous accompanying schedules and diagrams. Examples are given illustrating the application of the diagrams and formulas used in testing, and the methods of testing and machinery used are described and illustrated. In addition to the detailed descriptions a general summary of the results has been brought together on a large schedule, which shows the strength of the Western Australian hardwoods as compared with recent available data concerning the most important of the world's hardwoods.

In all 10 species of eucalypts were tested, of which the more important are jarrah, karri, tuart, blackbutt, wandoo, York gum, red gum, and yate. Several other kinds of wood were also tested. The heaviest of the Western Australian timbers, and of all the Australian timbers of note, were found to be yate and wandoo, which averaged 79 lbs. per cubic foot when first cut and remained the heaviest when seasoned at 12 per cent moisture. The strength of the weakest of Western Australian eucalypts is said to be equal to that of hickory and about 20 per cent greater than that of the best oak. Yate (*Eucalyptus cornuta*), common in the southeastern portion of the state, but still practically unknown as a timber, is believed to be the strongest "sawn" timber in the world, since in all of the present tests it was far ahead of the rest of the Australian hardwoods. In one tensile test this timber withstood a breaking load of 17½ tons per square inch, or about 3¼ tons below that usually specified for wrought iron of ordinary quality.

Forest trees of New Jersey, B. D. Halsted (*New Jersey Stas. Bul. 202, pp. 52, figs. 25*).—This bulletin contains a list of trees either native to or growing wild in New Jersey, and is intended to serve as a guide in the further tree canvass of the State and ultimately to aid in the work of developing a genuine and systematic sylviculture therein.

The list is based upon N. L. Britton's "Flora of New Jersey," published by the Geological Survey in 1889. Information with regard to localities for the species and further notes are derived from various sources, enumerated herein. The botanical names of the species are given, together with some of the common names and the area of distribution. A list of various forestry papers is given near the end of the bulletin, together with a brief digest of the various legislative acts relating to forestry. The engravings are from Sargent's "Manual of the Trees of North America."

Studies of species of forest trees, H. Hesselman (*Skogsvårdsfor. Tidskr., 5 (1907), No. 1, pp. 1-18, pl. 1, figs. 4*).—This is the first of a series of articles on different species of forest trees. The present paper deals with the delayed formation of chlorophyll in *Picea excelsa*, var. *versicolor*, notes on a mountain spruce of unusual type, and a discussion of pine trees with large seed production.—F. W. WOLL.

Notes on balsam fir, B. Moore and R. L. Rogers (*Forestry Quart., 5 (1907), No. 1, pp. 41-50*).—The authors made investigations near Frenchtown, in the north central part of Maine, on spruce and fir forests for the purpose of ascertaining the best sylvicultural practices for maintaining the proportions of spruce wherever possible, as well as to get the best results from the fir. Observations were made as to the tolerance, power of recovery after suppression, resistance to windfall, soundness at different ages and under different conditions, and rapidity of growth of fir as compared with spruce.

Fir was found to be less tolerant than spruce, and especially subject to windfall in north central Maine after a diameter of 15 in., breast high, is reached. In a pure stand fir is subject to rot at the butt after the age of 50 years, particularly in moist situations. When mixed with hardwoods the percentage of rot is said to be smaller and the trees are usually sound up to an average age of 85 years.

After windfall in a pure spruce flat or slope, a pure stand of fir follows, whereas on lowland areas, under normal conditions, the fir occupies less than 5 per cent of the stand, with an increasing percentage on upward slopes. After windfall in a spruce stand containing hardwoods, a stand predominantly hardwoods and fir results. On mixed hardwoods and spruce slopes the proportion of fir is doubled after each cutting. When the cut is too heavy the fir will surpass the spruce in the next generation.

In conclusion the authors state that although the fir is seen to be more abundant in the young growth after cutting, it is probable that in many cases it will eventually die out and its place be taken by the spruce. While the fir is growing, however, it is not only retarding the spruce but occupying space, and thus causing just so many years' loss of growing time to the spruce.

Hevea brasiliensis in Singapore, R. SCHLECHTER (*Tropenpflanzer, 11 (1907), No. 3, pp. 133–141*).—An account of the Hevea plantations of the botanical gardens of Singapore, dealing with the constitution of the stands, production of seed, and methods of harvesting the Hevea, together with a discussion of pure stand planting versus companion crop planting. The author believes that the attempt to keep down harmful weeds in pure stands is too costly, and suggests the use of cover crops, recommending such species as *Passiflora foetida*, *Crotalaria stricta*, and one of the Tephrosias, which will not only keep down harmful weeds but add plant food to the soil as well.

Where companion crops are desired admixtures of cacao, coffee, tea, peanuts, tapioca, and upland rice are recommended for different situations.

Latex and rubber of Parameria glandulifera from India (*Bul. Imp. Inst., 5 (1907), No. 1, pp. 14–16*).—This brief article states that *Parameria glandulifera*, a climbing plant, is distributed through southern Burma, Indo-China, and the Malay Peninsula, and has long produced a yield of good rubber, which is exploited by the native collectors. Samples of the latex and rubber of this plant have been forwarded to the imperial institute from Burma and the Andaman Islands, and the dry rubber was found to contain 91.8 and 91.6 per cent, respectively, of caoutchouc. In each case the percentages of resin and proteids are low and the rubber is free from vegetable impurities.

DISEASES OF PLANTS.

Studies in the inheritance of disease resistance, R. H. BIFFEN (*Jour. Agr. Sci., 2 (1907), No. 2, pp. 109–128*).—While studying the inheritance of certain characteristics of wheat the author was led to believe that possible liability and immunity to attacks of yellow rust were paired characters, and experiments were inaugurated to determine on an extensive scale whether immunity to attacks of different fungi might be transmitted in the usual Mendelian way.

The experiments consisted in crossing a number of varieties of cereals and testing their resistance to yellow rust, black rust, and a mildew of cereals (*Ery-*

siphe graminis). A considerable collection of varieties of wheat and barley was obtained and various grades of resistance were established by crossing the resistant and susceptible varieties. The hybridizing was done in 1904 and the results reported were observed during their growth in 1904 and 1905.

The results showed that crossing immune and susceptible varieties yielded offsprings susceptible to disease. Upon self-fertilization of these susceptible individuals, immune and susceptible descendants in a proportion of 1 of the former to 3 of the latter were secured. Where the degree of susceptibility differed in the two parents, the hybrid resembled the more susceptible parent in that respect. The relatively immune forms breed true to this characteristic in the succeeding generations. In all experiments the degree of susceptibility was found to be variable. Immunity appears to be independent of any discernible morphological character, and it is entirely practicable to breed varieties morphologically similar to one another but immune or susceptible to parasitic fungi.

A contribution to the biology of phanerogamic parasites, A. FRAYSSE (*Rev. Gén. Bot., 19* (*1907*), *No. 218, pp. 49–69, figs. 13*).—The author presents a résumé of his more extended work,[a] giving the results of his observations and experiments with a considerable number of phanerogamic parasites. The general biology of the parasites is described, after which their physiology is discussed.

In the species studied, the author found that the parasites attack the roots of the host plants by means of haustoria, and they are apparently limited to those hosts which offer large reserves of carbon compounds, such as are found in plants possessing bacterial tubercles, mycorrhiza, starch cysts, etc. The number of haustoria seems to be limited by the host plant, but their form and duration are determined by the necessities of the parasite. The haustoria are believed to represent modified roots which are adapted to the purposes of absorption through their peculiar mechanism.

In some chlorophyll-bearing species the parasite takes from the host only a portion of its mineral and organic carbon, while in others practically all of the organic carbon is received from the host plant. As a result of his experiments the author claims that glucose is the principal source of carbon taken up by the parasites, and that while starch is abundant in the host it is transformed into sugar by the diastases.

The haustoria are said to force their way into the host plant through the action of certain diastases, the most common of which is cellulase.

Bacterial diseases of fruits and vegetables, S. F. EDWARDS (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32* (*1906*), *pp. 136, 137*.—Observations are given of the bacterial diseases of fruits and vegetables which are noted as occurring during the season covered by the report.

The organism causing the black rot of cabbages and allied plants was found affecting kale, collards, Brussels sprouts, several varieties of cabbage, broccoli, cauliflower, kohl-rabi, ruta-bagas, and turnips. Some varieties of these vegetables were more severely injured than others.

The bacterial blight of the pear, quince, and apple continues to be destructive in Ontario and it was observed in the past season on ornamental varieties of the English hawthorn. This variety which is characterized by its double scarlet flowers had been planted as an ornamental quite extensively, but in July of the past season it was found to be affected by a blight. A study of the disease showed that it was due to the same cause as that producing pear blight (*Bacillus amylovorus*). The common English hawthorn does not appear to be affected so far as the observation has been made, but on account of the susceptibility of this variety a caution is given fruit growers against its planting.

---

[a] Contribution à la biologie des plantes phanérogames parasites. Thesis. Paris, 1906, pp. 180, figs. 51.

The cucumber wilt, *Bacillus tracheiphilus*, made its appearance during the season, but as it appeared late in summer did little injury. The author expects to carry on investigations regarding this organism.

A disease of strawberries is briefly described, which is characterized by the appearance of translucent spots which spread throughout the tissue of the green or ripe berries. When a berry is crushed its juice draws out in slimy threads. An organism having a yeast-like appearance has been isolated, and studies are being carried on as to its morphology and life history.

The soft rot of turnips and cauliflowers (*Bacillus oleraceæ*) has again appeared, but at the experiment station caused little loss.

Some injurious fungi found in Ireland, T. JOHNSON (*Econ. Proc. Roy. Dublin Soc., 1 (1907), No. 9, pp. 345–370, pls. 4, figs. 5*).—Attention is called to some of the more important plant diseases observed by the author. On account of the importance of the potato crop, especial mention is made of the potato diseases. Comparatively little loss was caused by *Phytophthora infestans* during the year. On the basis of extended observations the author seems to agree with Matruchot and Molliard that most of the rot of potato tubers is to be attributed to bacteria and not directly to the fungus.

A disease locally known as yellow blight is described, and the author states that while he formerly considered it due to *Sclerotinia sclerotiorum*, he is now satisfied that it is more commonly the work of bacteria than of fungi.

Attention is called to a number of diseases of potatoes which have been considered as caused by different species of bacteria, and while the organisms have many biological differences the author is not satisfied that they are all specifically distinct.

Several forms of potato scab are described. That caused by *Spongospora solani* is of scientific interest rather than economic importance. The scab attributed to *Phellomyces sclerotiophorus* is briefly mentioned, and the fungus is said to be identical in its fertile form with *Spondylocladium atrovirens*.

Notes are given on the winter storage of potatoes and on the heart rot of mangels, onion diseases and their remedies, gooseberry mildew (*Sphærotheca mors-uvæ*), oat smut, and barley leaf streak due to *Helminthosporium gramineum*, the ascospore stage of which, *Pleospora trichostoma*, has been but lately recognized.

[Report of the] department of botany, C. BROOKS (*New Hampshire Sta. Bul. 129, pp. 267–275, pls. 2, fig. 1*).—The season covered by this report was characterized by an excessive rainfall that was favorable to fungus diseases. The department kept a record of those reported and, so far as possible, gathered data in regard to the extent and nature of the injury done. The diseases, which are arranged according to the host plants, are briefly described and suggestions offered for their control. Most of those reported upon were of orchard fruits, grapes, potatoes, melons, and other garden crops.

In addition to investigations on plant diseases, work has been begun to determine the factors that control the formation of fruit buds on apples of the Baldwin variety. The results thus far obtained do not justify any definite conclusions, but it appears from the evidence at hand that it will be possible to produce annual crops on varieties that are accustomed to bear only on alternate years.

Treatment of grain for smut, J. Buchanan (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 176–178*).—A series of experiments to prevent the occurrence of smut was carried on with varieties of wheat and oats which were treated by immersion in dilute formalin, sprinkling with dilute formalin, immersion in hot water, immersion in dilute copper-sulphate solution for 12 hours, immersion in a strong solution of potassium sulphid for 2 hours, and sprinkling with a copper-sulphate solution. All of these treatments were more or less efficient in reducing smut in both the winter wheat and oats, the sprinkling with copper sulphate and immersion in potassium-sulphid solutions being the least efficient.

Another series of experiments was conducted with 2 varieties of oats, the seeds of which ranged from 1 to 5 years old, the object being to ascertain whether the smut spores would lose their vitality sooner than the oats. This experiment has been under way for 3 years, and up to the present has failed to show that the smut has lost its vitality to any appreciable extent.

For 2 years the author has endeavored to prevent smut on barley by treating the seed with formalin at the rate of 1 pt. to 42 gal. of water, but without success.

The stinking smut of wheat (*Bol. Sec. Fomento [Mexico], 2. ser., 6 (1907), No. 8, pp. 635–651*).—A brief report is given on an inquiry made by the agricultural experiment station at Ciudad Juárez relating to the distribution and amount of injury caused by the stinking smut of wheat. For its prevention the treatment of the seed wheat by soaking in copper-sulphate solution, after which the grain is dipped in strong lime water, is recommended.

Investigations on the alteration of grain and fodder, Brocq-Rousseu (*Bul. Soc. Nat. Agr. France, 67 (1907), No. 3, pp. 271–280*).—In a note by G. Bonnier to the Society of Agriculture of France a résumé is given of investigations on an important cause of changes in grain and forage. Grain and forage were found to be attacked by a species of Streptothrix, for which the name *S. dassonvillei* is proposed. The changes caused by the fungus are described at some length, and it is said its presence may be recognized by the peculiar musty odor which it gives to both grain and forage.

By heating grain to 50° C. the micro-organisms are said to be destroyed and the characteristic odor removed. A form of apparatus designed for the rapid treatment of the grain is described.

The formation of intumescences on potato plants, Gertrude E. Douglas (*Bot. Gaz., 43 (1907), No. 4, pp. 233–250, figs. 9*).—While experiments were being carried on in the botanical laboratory of the Cornell University to study the relationship of a soil fungus to potato plants, a number of young shoots were covered with bell jars and in a few days intumescences were formed in great numbers.

The presence of these outgrowths led to an investigation of the subject, and young plants were covered with bell jars and their roots supplied every day with an abundance of water. In from 2 to 5 days the intumescences were formed, usually appearing on the upper surface of the leaf, but in some cases occurring on the lower side also and scattered profusely over the upper part of the stem. To the naked eye they appeared as small greenish-yellow dots, projecting slightly from the surface of the leaf. These rapidly developed in size, became lighter yellow, hemispherical, smooth, and glossy, and after about 24 hours they became whitish, roughened, and projected prominently from the surface. These outgrowths lasted but a short time, and in a day or two they had collapsed and become dry and blackened. A cross-section of the leaf showed that they were due to the hypertrophy of the cells underlying the epidermis.

The swollen cells elongated, finally rupturing the epidermis, and the chlorophyll granules lost their green color, becoming yellowish and finally disappearing entirely.

A study as to the cause of this behavior showed that intumescences are produced on young potato plants from good tubers when transpiration is checked and the roots are rapidly absorbing water. They are formed abundantly both in bright light and in weak light, but they are not produced in total darkness. The abnormal state of turgescence of the hypertrophied cells is attributed to the osmotic action of glucose, assimilated in part by the leaf, but principally supplied to it from the underground tuber, which is richly provided with starch.

Rind disease of the sugar cane, L. Lewton-Brain (*Hawaiian Sugar Planters' Sta., Div. Path. and Physiol. Bul. 7, pp. 44, figs. 16*).—This bulletin, which consists of an address delivered by the author before the Sugar Planters' Association, describes the rind disease of sugar cane and a number of related stem diseases.

The rind disease, which is due to *Melanconium sacchari*, is of considerable importance and from the author's investigation seems to be a widely distributed disease. The first symptoms of its occurrence have been noted in the leaves, which dry up prematurely and turn yellow at the tips, the drying spreading until the whole leaf is dead. The outer leaves are first affected, and the whole tip of the stalk may become dry and dead, in which case attempts may be made to develop some of the buds lower down. By the time the dying of the leaves becomes noticeable other evidences of the disease are present. At this time if the cane be split open it will be found that the normally whitish color of the tissues is changed to a bright or dark red or reddish brown. In the next stage the discolored areas become sunken and lose their color, and later the internodes are shrunken and more or less covered with small, black, hair-like bodies. These are the spore masses which have been put out for the dissemination of the fungus.

In experiments carried on by the author he has found that the disease can be spread by rotten cane, and under field conditions the fungus probably attains access to the plant through wounds which are often caused by leaf hoppers or borers.

In connection with this disease the author discusses the red rot of cane, due to *Colletotrichum falcatum*, attention being drawn to this disease on account of the desire for information and also to correct some ideas regarding the relationship of the two fungi. The author claims that the rind disease and the red rot are quite distinct, and the fungus causing the rind disease is considered to be a wound parasite. However, if the vitality of the cane is lowered in any way, by lack of cultivation, moisture, etc., it becomes liable to attack by this fungus. The red rot is to be the subject of a future communication.

A discussion is given of the relation between *Melanconium sacchari* and *Thielaviopsis ethaceticus*, which causes the so-called pineapple disease of sugar cane. These two fungi are often believed to be different stages of the same fungus, but while inoculation experiments with Melanconium spores under certain conditions result in the production of spores and a diseased condition resembling that due to Thielaviopsis, the converse does not appear to have been demonstrated.

As practical suggestions for combating the rind disease the author recommends the destruction of infected material, the prevention of wounds as far as possible, the selection and disinfection of cuttings, cultivation so as to secure as rapid growth as possible, and the use of resistant varieties.

Some diseases of ginseng, H. H. Whetzel (*Spec. Crops, n. ser., 6 (1907), No. 57, pp. 86–90*).—In an address by the author an account is given of some of the more serious diseases to which ginseng is subject. Of these the most destructive one upon the above-ground parts of the plant is the Alternaria blight. This is due to an undetermined species of Alternaria, and it seriously affects the leaves, stems, and all of the above-ground parts. It has been shown that thorough spraying with Bordeaux mixture will entirely prevent this disease. Until recently the fungus on the wild plant was unknown, but during the summer of 1906 the author discovered it on ginseng plants growing wild in the woods.

Notes are also given on the soft rot of ginseng roots and a Rhizoctonia disease of the stems and roots.

The blossom end rot of tomatoes, Elizabeth H. Smith (*Massachusetts Sta. Tech. Bul. 3, pp. 19, figs. 6*).—Work on the tomato fruit rot was begun by the author in the spring of 1902 and was continued for some time, the present publication giving the results of the investigations.

The diseased condition of the fruit is readily recognized by the occurrence of spots around or at one side of the style. The infected area is slightly sunken, with a regular boundary, and clearly defined by a slightly raised ridge, beyond which the tomato is healthy. The diseased tissues are dry and leathery, of a light grayish-brown color, and on the larger spots rings of a darker color are visible near the boundary. In longitudinal sections through the spots the interior boundaries are as clearly defined as the outer ones.

A microscopical examination of the spots showed the presence of the fungus, which upon cultivation proved to be *Fusarium solani*. This fungus is believed to be the only active parasitic fungus connected with the fruit rot of tomatoes. Species of Macrosporium, Cladosporium, and Alternaria have been found in connection with tomato rots, but the author was unable to induce any of these fungi to grow upon green tomatoes.

In connection with these studies, other diseases of tomatoes were investigated, and a bacterial rot was studied in which the organism was isolated and infection induced by repeated inoculation experiments. One type of the bacterial rot developed characters which were indistinguishable from the characteristic blossom end rot due to Fusarium.

An apple rot due to Volutella, F. L. Stevens and J. G. Hall (*Jour. Mycol., 13 (1907), No. 89, pp. 94–99, pl. 1*).—A black rot of apples closely imitating in appearance that caused by Sphæropsis is described, which is said to have been observed in various sections of North Carolina.

In general the disease may be recognized by the occurrence of black rotten spots upon the fruit. The central and older portions of the decayed region are of an intense coal-black color, while the younger portion of the spots is brownish. A close inspection reveals the presence of slightly elevated pimple-like places on the cuticle. These become larger and more pronounced as the center of the spot is approached. On sectioning an apple through one of these areas the more recently attacked tissues will be found of a brownish color, while the older portions are black. While the decayed portions are softer than the healthy ones, the disease can in no sense be considered a wet rot, the softness being due to a spongy dryness rather than to a watery dissolution.

The organism causing the disease has been isolated and cultivated on various media, but in no case were spores formed on artificial media. When grown on sterilized apple twigs, however, spores were formed in great abundance. Inoculations made from mycelium grown in pure cultures developed the characteristic spots in a few days where the skin of the apple had been injured by pricking, but all attempts to secure inoculations through the unbroken cuticle were without success.

The fungus causing the disease has been determined as *Volutella fructi* n. sp., a technical description of which is given.

Nematodes on grape roots, J. M. Huergo (*Rev. Vitivin. Argentina, 3 (1906), Nos. 21, pp. 312–314; 22, pp. 324–327; 23, pp. 339–342; 24, p. 364; 4 (1907), Nos. 2, pp. 25, 26; 4, pp. 60, 61; 5-6, pp. 79–82*).—A description is given of the effect produced by *Heterodera radicicola* on grapevines, and directions are given for distinguishing the work of nematodes from that of phylloxera, with suggestions of means for combating nematodes.

Some tea and rubber diseases, C. Bernard (*Bul. Dept. Agr. Indes Néerland., 1907, No. 6, pp. 55, pls. 4*).—Descriptions are given of some fungus and insect injuries to *Thea assamica*, *Kickxia elastica*, and *Hevea brasiliensis*.

One of the most destructive diseases of tea is that caused by *Pestalozzia palmarum*. This fungus attacks the foliage, causing discolored spots on the leaves, which finally turn brown. When severely attacked the plant is greatly weakened. A study of the fungus indicated its identity with one that causes severe injury to young cocoanut trees. In fact the fungus appears to spread from cocoanut trees to tea plants. In combating this disease attention should be given the centers of infection, and when they are eradicated the attack on tea plants may be controlled by picking the diseased leaves and an occasional spraying with Bordeaux mixture.

A second disease of tea is that due to *Hypochnus theæ* n. sp., a fungus that forms felted mats and strands over the branches and leaves of the plant. The fungus seems to be a saprophyte, but from its abundance causes serious injury. Pruning the shrubs and the frequent application of Bordeaux mixture will hold this fungus in check.

The third disease of tea plants described is due to *Guignardia theæ*. It is believed that treatments similar to those recommended for the control of the black rot of grapes will be successful in its control.

The disease of Kickxia is due to one of the sooty molds (*Capnodium indicum* n. sp.) following attacks of scale insects, particularly *Lecanium* sp.

Upon Hevea the author reports the attacks of the larvæ of some undetermined borer and a disease of young trees due to mites.

Bordeaux injury, U. P. Hedrick (*New York State Sta. Bul. 287, pp. 103–189, pls. 8*).—On account of the repeated reports of injury to apples through spraying with Bordeaux mixture, the station undertook investigations in the spring of 1906 to determine the cause of Bordeaux mixture injury, conditions favoring the injury, and means for preventing it.

It was found that Bordeaux mixture injury is known wherever Bordeaux mixture is used as a fungicide, and that different species of plants are injured in different degrees, peaches, apricots, and Japanese plums being most susceptible to injury, and common plums, quinces, pears, and apples being injured in about equal degree. Varieties of all the above fruits differ in their susceptibility to injury.

It appears that the amount of the injury to a given species or variety of fruit will depend upon the specific susceptibility of the plant, the solvent properties of cell sap on the copper hydroxid, the permeability of the epidermis of the plant, and the weather conditions following spraying.

The injury on the fruit appears as small, round, black or brown specks, and later the injured specimens become rough and russeted by reason of a ruptured epidermis and layers of dead corky cells. In badly injured specimens the fruits are more or less distorted through shrinkage of the injured portions. A microscopical examination of the injured fruits shows the waxy covering and cuticle of the apple to have been largely destroyed, and such epidermal cells as remain have become much thickened and corky in appearance.

Apples affected by this injury do not keep well, and, after having been kept in cold storage, if the fruit is exposed to the air the affected parts soon become mealy and decay sets in.

Upon the leaves the injury is first shown by the appearance of brown spots of various shapes and sizes. Quickly following this the leaf tissues turn yellow and the leaves fall. When the injury is only slight the yellowing may not appear nor the leaves drop.

It was found in the investigations that Bordeaux mixture has a particularly harmful effect in destroying the tissues of the apple blossom.

Injuries from arsenites, frost, fungi, mites, and the action of drops of water on foliage are somewhat similar to the injury caused by Bordeaux mixture and are frequently confused with it.

The experiments carried on at the station show conclusively that the Bordeaux mixture on the fruit and foliage caused the trouble described above. The toxic substance seems to pass through the stomata and the basal cells of the plant hairs into the cellular tissue of the fruit, the black specks characterizing the first stage of the Bordeaux russeting being usually formed about a stoma. No conclusion could be reached as to how the toxic ingredient finds its way into the cellular tissues of the leaves, but since the dead spots are nearly always under heavy Bordeaux mixture stains it is believed that the dissolved salts enter osmotically into the cells of the leaf surface.

Different varieties of apples were found to vary in respect to the injury by Bordeaux mixture, and immunity to injury by Bordeaux mixture does not correspond with immunity to the apple scab fungus. Early spraying and wet weather favor the development of this injury, and in experiments in which the quantities of copper sulphate and lime were varied it was found that the more the copper sulphate the greater the injury, although an excess of lime did not prevent or greatly lessen the injury. It is recommended that in practice less copper sulphate should be used and spraying should be done in moderation, so as not to have the trees drip heavily. So far as possible the Bordeaux mixture should be applied only in dry weather, and equal amounts of lime and copper sulphate should be used. The author calls attention to varieties which are nearly immune to attacks of the scab fungus and upon these light applications of Bordeaux mixture should be made in average seasons.

A bibliography of the subject completes the bulletin.

Cause and control of Bordeaux injury, F. H. Hall and U. P. Hedrick (*New York State Sta. Bul. 287, popular ed., pp. 16, pls. 2*).—A popular edition of the above.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Statistics of hunting licenses, T. S. Palmer (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 54, pp. 24, figs. 2*).—From an examination of the statistics regarding hunting licenses it appears that in 1905, 10,000 nonresident and 511,000 resident licenses were issued to hunters in the United States and Canada and that the income from these licenses was more than $600,000. It is believed that a system of license fees is the only method of putting game protection upon an independent and self-sustaining basis. Notes are given on the changes in fees, statistics of resident and nonresident licenses, number of licensed hunters in the United States, cost of collection, and restrictions on the use of license funds.

Directions for the destruction of wolves and coyotes, V. Bailey (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 55, pp. 6*).—This is a condensed form of information already noted from another source (E. S. R., 18, p. 749).

Carbon disulphid as a squirrel killer, L. F. Henderson (*Idaho Sta. Press Bul. 11, n. ser., pp. 4*).—Experiments to determine whether a large or small amount of carbon disulphid was more economic and satisfactory in destroying ground squirrels were somewhat unsatisfactory, for the reason that apparently the minimum poisonous dose was not determined. A half tablespoonful is not always sufficient, and in some cases 2 tablespoonsful were used. Where a sufficient amount of carbon disulphid is used it apparently requires not more than 2 or 3 hours to destroy the squirrels.

Birds useful in the war against the cotton boll weevil, H. W. HENSHAW (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 57, pp. 4*).—It has been found that 38 species of birds eat the cotton boll weevil to a greater or less extent. In this connection special mention is made of orioles, the nighthawk, and various kinds of swallows and martins.

Value of swallows as insect destroyers, H. W. HENSHAW (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 56, pp. 4*).—Attention is called to the agency of swallows in the destruction of boll weevils and other injurious insects. Notes are given on the tree swallow, barn swallow, bank swallow, cliff swallow, and purple martin. The author suggests a simple means of protecting these birds and encouraging their nesting.

Index-catalogue of medical and veterinary zoology, C. W. STILES and A. HASSALL (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 39, pt. 17, pp. 1209-1304*).—A list of titles arranged alphabetically under authors' names from Maartens to Martirano.

Executive report of the Illinois State entomologist, S. A. FORBES (*Exec. Rpt. Ill. State Ent., 1905–6, pp. 27*).—During the years 1905 and 1906 great advance has been made in devising practical remedies for the control of insects. Nevertheless, enormous losses were caused by insects in Illinois, particularly by corn insects and San José scale. The work of the entomologist in the study of remedies for the corn aphis has been quite successful. Progress is also reported in devising means for combating white grubs, San José scale, and cottony maple scale.

In 1906, 239 nurseries were inspected at an average cost of $4.77, which, according to the State law, is charged against the nurseryman. A list is given of the nurseries inspected in Illinois.

[Report of the] department of entomology, E. D. SANDERSON (*New Hampshire Sta. Bul. 129, pp. 258–266*).—Reference is made to the entomological equipment and collection of the station and to insects received for identification. A list is given of the publications of the entomologist during the years 1905 and 1906.

A brief account is also given of the work of the station on the brown-tail moth, gipsy moth, codling moth, apple maggot, and insect pests of gardens and shade trees.

[Report of] the professor of entomology and zoology, C. J. S. BETHUNE (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 42–54*).—Brief mention is made of the instruction work in entomology at the agricultural college during 1906, and of correspondence, demonstrations, and publications on entomological subjects.

In field experiments in treating oyster-shell bark-louse, lime-sulphur wash gave the best results followed in efficiency by kerosene emulsion. In combating root maggots, the best results were obtained from an application of pyrethrum mixed with 4 times its weight of flour. Carbolic-acid emulsion also gave good results. Crude petroleum, pure and in emulsions, was tested as a spray on apple, pear, plum, and cherry trees, and black currants. It was found that in winter it is harmless to tender varieties of trees and is fully as effective as kerosene. In summer considerable danger attends its use.

Thirty-seventh annual report of the Entomological Society of Ontario (*Ann. Rpt. Ent. Soc. Ontario, 37 (1906), pp. 120, pls. 7, figs. 36*).—The forty-third annual meeting of the society was held at Guelph, Ontario, October 10 and 11, 1906, and the present report contains an account of the proceedings. The ravages of the codling moth and the natural parasites of this pest were discussed by J. Fletcher and W. Brodie (pp. 3–15). Brief notes on the insects of the year in various districts of Ontario were given by C. H. Young et al. (pp. 15–19). Similar notes on injurious insects were presented by C. J. S. Bethune (pp. 45–56) and J. Fletcher (pp. 81–89).

Other matters discussed at the meetings included the insect galls of Ontario, insects injurious to linden, locust mite, oyster-shell bark-louse, bean weevil, San José scale, and various species of hemiptera.

Report on injurious insects and plant diseases for 1906, W. M. Schoyen (*Beretning om Skadeinsekter og Plantesygdomme i Land- og Havebruget 1906. Christiania: Grondahl & Sons, 1907, pp. 30, figs. 14*).—During the year under report attention was given to fruit flies, grain aphis, wheat rust, and a number of other insect pests and fungus diseases of cereals, clover, and garden crops, particularly cabbage, potatoes, tomatoes, and melons. The depredations of certain fruit pests are also noted, particularly pear blister-mite, currant sawfly, and *Lecanium ribis*.

Entomological work of the state agricultural institute in 1906, Poskin (*Bul. Agr. [Brussels], 23 (1907), No. 2, pp. 115–161*).—A general outline is given of the conditions under which specific insecticide treatments are indicated for the control of injurious insects. Particular attention is given to suitable insecticides for the treatment of biting insects. The formulas commonly proposed for Paris green, London purple, and arsenate of lead are discussed and recommendations are given regarding the time and method of application of these insecticides.

The grasshopper problem and alfalfa culture, F. M. Webster (*U. S. Dept. Agr., Bur. Ent. Circ. 84, pp. 10, figs. 8*).—During the past few years serious depredations have been reported from the attacks of grasshoppers on alfalfa. The species chiefly concerned are *Melanoplus differentialis* and *M. bivittatus*. Notes are given on the habits and life history of these grasshoppers. About 100 species of birds are known to feed upon them, and they are also held in check to some extent by the attacks of insect parasites and a fungus disease.

Wherever the grasshoppers are abundant, however, it is necessary to adopt artificial means of repression. The best means are the destruction of the eggs by plowing or harrowing, catching the young grasshoppers in hopperdozers, and the use of poisoned baits, particularly Criddle mixture.

The cotton bollworm, F. C. Bishopp and C. R. Jones (*U. S. Dept. Agr., Farmers' Bul. 290, pp. 32, figs. 4*).—The life cycle, food plants, seasonal history, and injuries caused by the bollworm are briefly outlined. In combating this pest the authors recommend thorough fall or winter plowing, the use of early varieties of cotton, heavy fertilization, early planting, and frequent cultivation.

The spring grain-aphis, F. M. Webster (*U. S. Dept. Agr., Bur. Ent. Circ. 85, pp. 7, figs. 3*).—The general appearance, seasonal history, food plants, outbreaks, and natural enemies of this pest are briefly noted. The author believes that the pest is usually held in check by its natural enemies and by unfavorable climatic conditions. Late sowing is suggested as a means of preventing an attack of the aphis upon fall grain and rolling or brushing are recommended for reducing the infestation of grain.

The corn leaf-aphis and corn root-aphis, F. M. Webster (*U. S. Dept. Agr., Bur. Ent. Circ. 86, pp. 13, figs. 4*).—It is uncertain whether there is any genetic connection between these 2 plant lice. The root-aphis is the only one which causes serious trouble. This insect is described in its various stages and notes are given on its life history.

In combating the pest the best results are had from adopting a system of crop rotation, stirring the soil after plowing and before cultivating the crop, plowing the soil in the fall or winter, making heavy applications of barnyard manure, and treating the seed corn with a mixture of wood alcohol and oil of lemon. The last-named remedy was advised by Professor Forbes of the Illinois Station.

The strawberry root-louse: Life history and remedies, C. O. HOUGHTON (*Delaware Sta. Circ. 2, pp. 4*).—The life history of this insect is briefly outlined. In controlling the pest good results are to be expected from burning over old strawberry beds, dipping infested plants in tobacco tea prepared by boiling for one-half hour 1 lb. of tobacco stems in 1 gal. of water, or fumigation with hydrocyanic-acid gas.

New hemipterous fruit pests in Britain, F. V. THEOBALD (*Jour. Econ. Biol., 2 (1907), No. 1, pp. 14-25, pls. 2*).—A considerable variety of leaf-hoppers have caused serious damage to all kinds of orchard trees and bush fruits. The author gives an account of the biology of *Typhlocyba quercus*, *Chlorita flavescens*, and *C. viridula*. Several natural enemies and parasites of these pests have been collected. The nymphs of these leaf-hoppers may best be destroyed, in the opinion of the author, by treating infested trees or shrubs with kerosene emulsion containing 3 gal. of oil to 100 gal. of water.

Spraying for the codling moth, J. W. LLOYD (*Illinois Sta. Bul. 114, pp. 375-429, figs. 5*).—Orchardists throughout the State of Illinois follow the practice of spraying their orchards 3 times a year, using Bordeaux mixture and Paris green, or some other arsenical, for the purpose of combating apple scab and codling moth at the same time. The first application is usually directed against apple scab, but Paris green is added to the mixture in order to poison canker worms. The second application is commonly made immediately after the petals fall and the third a week or 10 days later.

The subject of combined spraying for codling moth and apple scab was carefully investigated by the author. It appears that the first application for the codling moth should be timed preferably with reference to the most advanced young apples rather than to the average development of the entire setting. It is concluded that spraying for the first brood of the codling moth may take place as soon as most of the petals have fallen and should be completed within 7 days from that date. It is desirable to use at this time a large amount of spraying material and apply it under high pressure. This treatment is aimed at the first brood of codling moth and the calyx end of the apples should be well filled with the insecticide.

Since the larvæ of the second brood continue to appear during a period of 4 or 5 weeks, it is necessary to make repeated applications in order to keep them fairly in check. If the first treatment is carefully done subsequent applications will be less important.

The use of a simple mixture of Paris green and water is not recommended for the reason that it injures the foliage and causes dropping of the apples. The best results are obtained from the use of Paris green in Bordeaux mixture at the rate of ¼ lb. to 50 gal. of water, or 25 oz. of lead acetate and 10 oz. sodium arsenate in 50 gal. of water.

Two common scale insects, C. O. HOUGHTON (*Delaware Sta. Circ. 3, pp. 6, fig. 1*).—A brief account is given of the life history, habits, and food plants of the oyster-shell scale and scurfy scale. In combating the oyster-shell scale the author recommends the application of kerosene emulsion shortly after the emergence of the young. The same remedy may also be used for scurfy scale.

The San José and other injurious scale insects of Tennessee with methods for their control, G. M. BENTLEY (*Tennessee Sta. Bul., Vol. XIX, No. 2, pp. 11–34, figs. 23*).—A popular review is given of the history, introduction, distribution, habits, and life history of the San José scale with notes on its food plants and the extent of its injuries. Boiled lime-sulphur wash is recommended as the best remedy for this pest from a standpoint of both cheapness and efficiency. Brief directions are given for preparing and applying remedies for the San José scale, and short notes on the oyster-shell scale, scurfy scale, cottony-maple scale, rose scale, and apricot scale.

Capnodis tenebrionis, a fruit pest, LATIÈRE and GUÉNAUX (*Bul. Soc. Nat. Agr. France, 67 (1907), No. 3, pp. 268–271*).—This insect attacks the trunks of the peach and cherry trees. It is difficult, if not impossible, to prevent the deposition of the eggs on the bark by the use of sticky substances. It is suggested that the larvæ in the trunks be destroyed by the use of wires inserted into the tunnels.

Description of a new genus and species of scale insect on the olive, A. BERLÉSE and F. SILVESTRI (*Redia, 3 (1905), No. 2, pp. 396–407, figs. 18*).—*Euphilippia olivina* is described as new and notes are given on its life history. This scale insect lives upon the olive and has been found in large numbers in several localities. It appears that there is but one brood annually and that the eggs are laid in the month of May.

A probably effective method of destroying Ceratitis capitata and Rhagoletis cerasi, A. BERLÉSE (*Redia, 3 (1905), No. 2, pp. 386–388*).—The gratifying success had by the author in combating the olive fly by a mixture containing honey, molasses, glycerin, and an arsenical leads him to believe that the same method may be used effectively against fruit flies.

The locust borer and methods for its control, A. D. HOPKINS (*U. S. Dept. Agr., Bur. Ent. Circ. 83, pp. 8, figs. 4*).—A brief statement is made regarding the damage caused by this insect, the means by which its attacks may be recognized, and measures for its control. It is recommended that locusts be cut for timber or in thinning operations between October 1 and April 1. If it is desired to destroy badly infested trees they should be cut in May and June when they contain the greatest number of the borers. Beneficial results have been noted as a result of spraying trunks and branches of trees with kerosene emulsion. Some attention has also been given to breeding a resistant race of trees.

Pinhole injury to girdled cypress in the South Atlantic and Gulf States, A. D. HOPKINS (*U. S. Dept. Agr., Bur. Ent. Circ. 82, pp. 4, fig. 1*).—Observations were made on 300 cypress trees for the purpose of studying the various species of insects which are connected with injury to the wood and bark of living or dead trees. The principal injury appeared to consist of pinholes in the sapwood and heartwood caused by ambrosia beetles and pin borers. The most injurious species is *Platypus compositus*. In combating these pests the author recommends that girdling operations be carried on in October and November and that worthless gum or cypress trees be left as traps in the proportion of 1:50–70 trees to be girdled.

The spruce-gall and larch-blight diseases caused by Chermes, and suggestions for their prevention, E. R. BURDON (*Jour. Econ. Biol., 2 (1907), No. 1, pp. 1–18, figs. 2*).—A general study was made of the life history and appearance of the various developmental stages of Chermes on spruce and larch. The complicated life history of these insects is shown in a tabular form. Many remedies have been tested in preventing the ravages of spruce-gall insects, but, according to the author's experience, the best results are to be expected from the use of a comparatively weak kerosene emulsion. If this remedy is applied in spruce timber it will also be necessary to treat larch in the immediate neighborhood to prevent the reinfestation of the spruce.

Chermes of Colorado conifers, C. P. Gillette (*Proc. Acad. Nat. Sci. Phila., 59 (1907), No. 1, pp. 3–22, pls. 11*).—The species of Chermes found on conifers in Colorado are described in detail, several of them being new. Notes are also given on the habits of these species.

An ecological and experimental study of Sarcophagidæ with relation to lake beach débris, W. B. Herms (*Ohio State Univ., Contrib. Dept. Zool. and Ent., No. 24, pp. 39; reprinted from Jour. Expt. Zool., 4 (1907), pp. 45–83, figs. 7*).—After the occurrence of storms along the shores of the Great Lakes there is a greater or smaller amount of vegetable and animal débris left upon the beach. The author made a study of the agency of insects, particularly flies of the family Sarcophagidæ, in the destruction of this organic material. It appears that the most common members of this family, particularly *Lucilia cæsar*, are most effective in destroying the animal and vegetable matter which would otherwise become a source of nuisance.

Experiments were carried on to determine the reaction of the larvæ of these flies to chemical substances, light, and gravity.

The danger of flies, A. E. Shipley (*Sci. Prog. Twentieth Cent., 1 (1907), No. 4, pp. 723–729*).—Attention is called to the importance of flies in the contamination of various food products and in the distribution of infectious diseases.

Some practical directions for making oil emulsions, C. L. Penny (*Delaware Sta. Circ. 1, pp. 6*).—Formulas are given for the preparation of soap solutions, mixtures of kerosene or crude oil and rosin oil, and other mixtures containing proprietary preparations of oils in combination with other standard forms of kerosene or crude oil. It has been found that some of the proprietary soluble oils separate and it is, therefore, recommended that they be thoroughly mixed before using.

Control of insect pests and diseases of Maryland crops, J. B. S. Norton and T. B. Symons (*Maryland Sta. Bul. 115, pp. 145–210, figs. 38*).—A general description is given of the kinds of damage caused to crops by insects and fungus diseases. Formulas are presented for the preparation of standard insecticides and fungicides and directions are given for their application. A considerable portion of the bulletin is occupied with an alphabetical list of cultivated crops with notes on their common insect and fungus enemies and remedies for the control of these pests.

Spraying the apple orchard, E. D. Sanderson, T. J. Headlee, and C. Brooks (*New Hampshire Sta. Bul. 131, pp. 11–56, figs. 36*).—The present status of the apple industry in New Hampshire is briefly outlined. The life history of the codling moth is described and a summary is presented of spraying experiments in New Hampshire during 1906. In the spraying experiments reported by the author it was found that at the average price of winter apples a profit of $1 to $1.35 per tree may be secured by 2 sprayings for the codling moth. Attention is also called to the value of scraping loose bark from the trees in order to destroy the favorable locations for the hibernation of the codling moth.

When arsenicals are mixed with Bordeaux mixture, apple scab and fruit spot are also largely held in check.

Spraying, L. R. Taft (*Michigan Sta. Spec. Bul. 37, pp. 32, figs. 10*).—The recommendations brought together in the present bulletin concern measures for the control of the San José scale, potato blight, black rot, and mildew of grapes, and other diseases. The sulphur and lime mixture is recommended as the most efficient and cheapest remedy for the control of the San José scale and it also has the advantage of checking a number of fungus diseases. Practical suggestions are made regarding the selection of spraying machinery and the time and method of application of insecticides and fungicides to orchard and other crops.

Spraying calendar, L. R. TAFT and C. D. SMITH (*Michigan Sta. Spec. Bul. 36, folio*).—Formulas are given for the preparation of standard insecticides and fungicides and dates are recommended for the application of these materials in the control of the chief insects and fungus diseases of various cultivated plants.

The biology of Litomastix truncatellus, F. SILVESTRI (*Ann. R. Scuola Sup. Agr. Portici, 2. ser., 6 (1906), pp. 1–51, pls. 4, figs. 13*).—This species was taken as an example of hymenopterous parasites and all features of its biology were studied in detail, beginning with the development of the young parasite in the egg of *Plusia gamma*, its host.

According to the author's observations the larval life of the parasitized Plusia is 3 or 4 days longer than that of healthy larvæ and the larva reaches a greater size than is normally the case. The generations of the parasite correspond strictly with those of the host insect.

Parasites of leaf-hoppers. Leaf-hoppers, R. C. L. PERKINS and C. W. KIRKALDY (*Hawaiian Sugar Planters' Sta., Div. Ent. Bul. 4, pp. 66*).—The descriptive material contained in this bulletin is based almost entirely on studies of leaf-hoppers and their parasites collected by Koebele in Arizona. The new species and genera of hymenoptera noted in the report belong chiefly to the family Dryinidæ, but other families are represented. A number of new genera and species of leaf-hoppers are also described.

Hosts of insect egg parasites in North and South America, A. A. GIRAULT (*Psyche, 14 (1907), No. 2, pp. 27–39*). A classified list is given of host insects the eggs of which are attacked by true egg parasites, together with a bibliography relating to the subject.

[Report of] the lecturer in apiculture, H. H. ROWSOME (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), p. 211*).—An experiment was tried in protecting colonies of bees in order to increase the heat inside the colonies during the time of the most active manufacture of wax. It has been found that in exceptionally mild winters there is little benefit from the use of too expensive and elaborate arrangements of protecting bees.

Breeding bees by selection, F. W. L. SLADEN (*Brit. Bee Jour., 35 (1907), No. 1296, pp. 164, 165*).—Attention is called to the difficulty of carrying on breeding experiments with bees, particularly in being sure of the ancestry of drones selected for this purpose. In most localities it is practically impossible to find for breeding experiments an isolated place in which no other bees are raised. The best system of selection appears to be the one in which dependence is placed upon the color of the bees.

A method of swarm control, W. C. LYMAN (*Amer. Bee Jour., 47 (1907), No. 20, pp. 411–413, figs. 4*).—A description is given of a device tested by the author in which swarming is controlled in a satisfactory manner. A brood chamber is connected with the main hive by means of a passage which opens in front near the entrance to the main hive. The bees are thus given additional room for rearing the brood and for accommodating the increasing colony without the necessity of swarming.

Handmade comb foundation, J. SUREAUD (*Apiculteur, 51 (1907), No. 3, pp. 115–120*).—The difficulties and advantages of preparing comb foundation at home are briefly outlined by the author, who has had considerable experience along this line. It has been found that when a thick foundation is given to the bees they are able to draw it out to the normal thickness without losing any of the wax. This process takes place rapidly and foundations prepared by hand in the manner recommended by the author are said not to break or bend.

Tussah or wild silk, W. PONTIUS (*Daily Consular and Trade Rpts.* [*U. S.*], *1907, No. 2863, pp. 5–7*).—Silk from cocoons, the worms of which were fed on oak leaves, is referred to as a wild silk. A brief account is presented of the extent of the industry in this material.

The weight of silkworm cocoons, G. TRENTIN (*Rivista, 4. ser., 13* (*1907*), *No. 9, pp. 207–211*).—Attention is called to the discrepancies in the average weights given by different authorities for silkworm cocoons of the same race. It is indicated that these weights are sometimes stated too high.

FOODS—HUMAN NUTRITION.

Iron in food and its functions in nutrition, H. C. SHERMAN (*U. S. Dept. Agr., Office Expt. Stas. Bul. 185, pp. 80*).—This report includes a general discussion of iron in food and its functions in nutrition, together with the results of 3 metabolism experiments in which the balance of income and outgo of nitrogen, iron, phosphorus, calcium, and magnesium were determined, as well as the results of 2 dietary studies undertaken with special reference to the iron content of the food consumed. Estimates are also given of the iron taken per man per day in 20 dietary studies made under the auspices of this Office in different parts of the country and reported in earlier bulletins. The experimental results obtained are discussed in the light of previous investigations and the report as a whole constitutes a summary of data on iron and its functions in food.

According to the author, the body of a man weighing 60 to 70 kg. contains 3 to 3.5 gm. of iron, the greater part of which exists as a constituent of the hemoglobin of the red blood corpuscles, while much of the remainder is contained in the chromatin substance of the cells. "Iron is probably an essential constituent of all nucleo-proteids. The iron-compounds of the body are therefore very prominent in the general metabolism and oxidative processes of the organism as a whole, and apparently also in the particular activities of the secreting and other specialized cells.

"Notwithstanding the constant and varied activities of the iron compounds in the body, the amount of iron so metabolized as to be eliminated is small—in fasting experiments, 7 to 8 mg.: in metabolism experiments with restricted diet, 5.5 to 12.5 mg. per day. Hence the daily waste of iron probably amounts to only 2 or 3 parts per 1,000 of that contained in the body. The small amounts of iron katabolized and eliminated are normally replaced by the organic iron compounds of the food. The food-iron is absorbed from the small intestine, deposited mainly in the liver, spleen, and bone marrow, and is finally eliminated almost entirely through the intestinal walls, only a very small proportion leaving the body by way of the kidneys.

"Approximate estimates of the iron contents of 20 American dietaries regarded as typical show a minimum of 7 mg. per man per day in the case of a negro family in Alabama and a maximum of 35 mg. in the food of Maine lumbermen at very active work combined with exposure to cold. The majority of dietaries furnish 11 to 19 mg. of iron per man per day. Throughout the 20 dietaries the amounts of iron run nearly parallel with the amounts of protein, the milligrams of iron per 100 gm. of protein in the diet varying only from a minimum of 15 to a maximum of 20. The relation of iron to protein is thus practically the same in ordinary mixed diet as in meat, so that the addition of meat to a mixed diet does not make it richer in iron relatively to protein.

"Increase of iron in the diet without a corresponding increase of protein is readily accomplished by the use of vegetables, fruits, and the coarser mill products of the cereal grains. In the experimental dietary here reported the free use of such foods with milk but without meat or eggs resulted in an increase of 30 per cent in the iron content of the diet, while the protein, the fuel value, and the cost remained practically the same as in the ordinary mixed diet obtained under the same market conditions."

The distribution of phosphorus in food materials, BALLAND (*Jour. Pharm. et Chim., 6. ser., 25 (1907), No. 1, pp. 9–12*).—A brief summary of results of a large number of determinations of the phosphorus content of food materials. According to the author the phosphorus estimated as P_2O_5 varied from 0.65 to 1.11 per cent in commercial wheat. The same values were found in oats. In maize, millet, barley, rye, and buckwheat the maximum was about 0.8 per cent. No values were determined for unpolished rice, but in the polished material the proportion was 0.25 per cent. Data are also given regarding the distribution of phosphorus in milling products, a number of vegetable foods, fruits, meat, cheese, and other foods.

The distribution of sulphur in foods, BALLAND (*Jour. Pharm. et Chim., 6. ser., 25 (1907), No. 2, pp. 49–51*).—A summary of the results of determinations of sulphur in cereals, vegetables, legumes, and fruits. The amount of sulphur in wheat ranged from 0.027 to 0.072 per cent, or, estimated as sulphuric acid, from 0.084 to 0.222 per cent.

Breakfast foods: Their chemical composition, digestibility, and cost, R. HARCOURT (*Jour. Soc. Chem. Indus., 26 (1907), No. 6, pp. 240–243*).—In addition to experiments on the digestibility of breakfast foods when forming a part of a simple mixed diet, which have been noted from another publication (E. S. R., 18, p. 460), data are given regarding the effects of cooking oat and wheat meals, rolled oats, and wheat farina for periods of 20 minutes, 2, 5, and 8 hours.

According to the author, the farinas, etc., "are more readily broken down through the action of heat than the oatmeals. With the latter there was only 14.95 per cent solids in the extract at the end of 20 minutes' cooking, whereas with farina, 27.4 per cent was soluble. A portion of the extract obtained from the wheat boiled for 20 minutes was hydrolyzed, when it reduced copper equivalent to 23.85 per cent of dextrose or 21.46 per cent of starch. After hydrolysis a portion of the extract taken from the meal boiled for 8 hours reduced copper equivalent to 37.65 per cent of dextrose, or 33.88 per cent of starch."

The digestibility of these foods when cooked for 20 minutes and for 8 hours was also studied with the results which are given in the following table:

Digestibility of rolled oats and wheat farina cooked for long and short periods.

Kind of food.	Organic matter	Protein	Fat	Carbohydrates.
	Per cent	*Per cent*	*Per cent.*	*Per cent*
Rolled oats (cooked 20 minutes)	94.2	81.5	92.5	98.0
Rolled oats (cooked 8 hours)	95.4	84.3	94.6	98.3
Wheat farina (cooked 20 minutes)	95.5	79.3	94.9	98.3
Wheat farina (cooked 8 hours)	95.3	79.4	95.6	95.5

"It is evident that the length of time the meal was cooked did not very materially influence the percentage amount digested. It is, of course, possible that less energy may have been expended in digesting that which was cooked the longer time; but no figures could be procured on this point."

Breakfast foods, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 63–68*).—The data reported are noted above.

The proteid content of wheat as an index to its bread-making qualities, A. J. PATTEN (*Rpt. Mich. Acad. Sci., 8 (1906), pp. 75–77*).—The summary of data prepared led to the conclusion that no hard and fast rule can be laid down for determining the bread-making value of wheats and flours. The most useful chemical tests in the author's opinion are the determination of the total protein and the determination of gliadin.

"Midzu ame," a new foodstuff, O. VON CZADEK (*Ztschr. Landw. Versuchsw. Österr., 9 (1906), No. 9. pp. 891, 892*).—An analysis is reported of a Japanese food product prepared usually from rice by the action of malt. The specimen analyzed was in appearance and taste not unlike honey.

The behavior of several lichen carbohydrates in the human body and their use in diabetes mellitus, E. POULSSON (*Upsala Läkareför. Förhandl., n. ser., 11 (1906), Sup. XIV, pp. 25*).—The carbohydrates of *Cetraria islandica* and *Cetraria nevalis* were studied and found to be similar, consisting in part of lichenin or a similar substance, which on hydrolysis gives δ-glycose and in part of hemicelluloses, which are probably anhydrids of δ-mannose and δ-galactose. Experiments showed that about 46 to 49 per cent of the carbohydrates of a sort of bread made from Iceland moss (*Cetraria islandica*) was digested. A similar bread made from *Cetraria nevalis* caused such disturbances that the experiment had to be discontinued.

Use of fruit as food, C. F. LANGWORTHY (*U. S. Dept. Agr., Farmers' Bul. 293, pp. 38, fig. 1*).—A revision and extension of an article of similar title previously noted (E. S. R., 18, p. 259). The table of composition of fruit and fruit products has been materially extended, and considerable new matter has been incorporated in the text. The principal topics discussed are the wild and cultivated fruits, market conditions and fruit supply, composition, color and flavor of fruits, ripening and its effect on composition, digestibility of fruit, cooking and its effects on fruit, jelly making, handling and storing fruit, and the hygiene of fruit.

A summary of statistical data regarding the present state of the fruit industry in the United States shows that there has been a decided gain both as regards fresh and preserved fruits, and there are reasons for believing that even the present development represents only a beginning. "This being the case, it is easy to understand why the agricultural experiment stations have devoted so much of their time to the study of fruit products, the marketing of fruit, and related problems, and why the place of fruit and fruit products in the diet and their value as food should be regarded as an important subject for investigation."

Banana flour, C. DRIEBERG, (*Queensland Agr. Jour., 18 (1907), No. 1, pp. 25–28*).—A summary of data from the Ceylon Tropical Agriculturist in which statistics of the commercial value of banana flour, the possible yield, different methods of manufacture, and similar topics are summarized.

In the author's opinion there is no great future for this industry, as the prices at which banana flour can be sold are not profitable. He believes that it has a marked value in infant and invalid dietetics, though it "is at a decided disadvantage when competing with cereal flours, which are much more cheaply produced."

Fruit juice statistics, 1906 (*Ztschr. Untersuch. Nahr. u. Genussmtl., 12 (1906), No. 12, pp. 721, 722*).—A summary of data regarding the character of commercial fruit juice for the year 1906 made up of articles on raspberry juice, by P. Buttenberg, H. Hempel, A. Friedrich, and H. Lührig; on blueberry, cherry, currant, gooseberry, raspberry, and blackberry juice, by E. Thamm and A. Segin;

on raspberry, strawberry, currant, and cherry juices and sirups, and on lemon and apple juice, by A. Juckenack, G. Büttner, and H. Prause; and on raspberry, cherry, currant, blueberry, and strawberry juice, by E. Baier and P. Hasse.

Judging the quality of raspberry jam, H. Kober (*Ztschr. Öffentl. Chem., 12 (1906), No. 20, pp. 393–398*).—Samples of raspberry jam made under the author's supervision were analyzed, and in his opinion it is not possible to fix upon maximum and minimum figures for the proportion of insoluble material in such goods, since there is no uniformity among manufacturers regarding the proportion of berries and sugar used and the degree of cooking.

Blueberry juice and the reaction which it shows under given conditions, W. Plahl (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 1, pp. 1–5*).—Blueberry juice, when treated with lead acetate, gave, after the removal of the lead, proper filtration, and concentration, a blue color when heated with hydrochloric acid and alcohol. The juice of a number of other species of vaccinium also gave this reaction, and the author believes that it is due to the presence of a glucosid, but further investigations are needed to prove this. The color reaction could not be obtained with the juice of cherries, grapes, elderberries, and currants. Data are also given regarding the composition of commercial blueberry juice.

The food and medicinal value of ice cream, J. A. Wesener (*Amer. Food Jour., 2 (1907), No. 2, pp. 31–33*).—A paper with discussion in which the nutritive value of ice cream, the comparative merits of pasteurized and sterilized milk for ice-cream making, and other questions are considered.

Buttermilk as a food and remedial agent, W. Gerassimowitsch (*Vrach [St. Petersb.], 5 (1906), pp. 578–581, 606–608; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 1, p 34*).—On the basis of observations with sick and healthy children, the author concludes that buttermilk obtained from sour cream is valuable as a food and remedial agent, but is not equal to woman's milk.

Analyses of Spanish paprika, A. G. Stillwell (*Jour. Amer. Chem. Soc., 28 (1906), No. 11, pp. 1603–1605*).—Standards are proposed for pure pepper (sweet) of high grade, for second grades containing some seeds, and for the lowest grade peppers containing practically nothing but seeds and stems. Olive oil is added to heighten the color of red peppers, and on this account the author considers that some of the samples which he examined containing more than 12 per cent total ether extract should be looked upon as suspicious.

Concerning the fruit of Capsicum annuum, A. Nestler (*Ztschr. Untersuch. Nahr. u. Genussmtl., 11 (1906), No. 11, pp. 661–666, pl. 1*).—Studies are reported of the crystals found in the secretory ducts and of the proteid and calcium oxalate crystals found in *Capsicum annuum*.

According to the author, the paprika plant is rich in calcium oxalate, the substance being found in considerable quantity even in the cotyledons of the young plant.

Studies in experimental alcoholism, R. Hunt (*Pub. Health and Mar. Hosp. Serv. U. S., Hyg. Lab. Bul. 33, pp. 43*).—From an extended series of experiments with small animals the author concludes that in some respects "the action of alcohol as a food is different from that of carbohydrates, and . . . that in all probability certain physiological processes in 'moderate drinkers' are distinctly different from those in abstainers." It was found that animals to which alcohol had been administered for some time in doses far too small to cause symptoms of intoxication or anatomical lesions which could be detected by present methods acquired an increased susceptibility to a definite poison, acetonitrile.

"It is believed that these experiments afford clear experimental evidence for the view that extremely moderate amounts of alcohol may cause distinct changes in certain physiological functions and that these changes may, under certain circumstances, be injurious to the body."

Researches on the nitrogenous constituents of malt which are soluble in cold water, and are not coagulated on boiling (*Trans. Guinness Research Lab., 1 (1906), pt. 2, pp. 167–283*).—A number of papers on various questions concerning the nitrogenous constituents of malt are reported and discussed, the investigations as a whole having relation to the use of malt in brewing.

The excretion of boric acid from the human body, H. W. Wiley (*Jour. Biol. Chem., 3 (1907), No. 1, pp. 11–19*).—From the author's investigations on borax, some of which have been reported in full (E. S. R., 16, p. 182), the general conclusion is reached that "the total quantity of boric acid excreted in the feces and perspiration is not much if any over 3 per cent of that administered during the ordinary period of observation. It is evident, therefore, that even including these quantities with those which are excreted in the urine not over 85 per cent of the total amount of boric acid exhibited in these experiments is in the three excretions mentioned."

The possibilities of the excretion of borax in milk were studied with nursing women. The data obtained indicate that "appreciable quantities of boric acid administered to the mother are found in the lacteal secretion. The quantity is quite variable and increases or decreases without much relation to the exact date of administration of the preservative. It is evident that the residue of boric acid which is stored in the body may at any time be expected to appear in the milk. Properly this investigation should have been completed by a study of the animal body itself after the administration of boric acid for a certain period to determine in what organs the part which escapes excretion is principally stored. Theoretically, from the results of the metabolic experiments, a large part of it would be found in the bones, or other phosphatic tissues, since it was seen that the administration of the boric acid largely increased the excretion of phosphorus. It is our intention in the near future to complete the experiment by feeding animals borax or boric acid for a period and then examining their bodies to determine the quantity of borax stored and its distribution."

Formic acid as a preservative, G. Lebbin (*Chem. Ztg., 30 (1906), No. 82, pp. 1009–1011*).—Strong acetic acid is known to be harmful. From experimental data the conclusion was drawn that if used as a preservative formic acid may be considered as twice as active physiologically as acetic acid.

The rational feeding of the aged, L. Landouzy (*Presse Méd. [Paris], 1907, No. 5, pp. 33–35*).—A French law, enacted in 1905, provides for the assistance of septuagenarians and the author discusses the subject of the preparation of a rational and adequate diet under the provisions of the law. According to his estimates, a man 70 years old and weighing from 60 to 70 kg. requires per day about 47 gm. protein, 53 gm. fat, 259 gm. carbohydrates, and 20 gm. of alcohol, supplied in a quarter of a liter of wine, the total fuel value of the diet being about 1,950 calories. In order that the menus may be readily varied and remain equivalent in nutritive value, data are given regarding the quantities of different food materials calculated to be equivalent in nutritive value.

Some common errors in the diet and general hygiene of children, A. F. Voelcker (*Brit. Med. Jour., 1907, No. 2404, pp. 181–185*).—Diet, feeding, clothing, ventilation, exercise, and similar questions are discussed. The author makes a plea for breast feeding in hospitals, when possible, as opposed to artificial feeding.

Improper feeding of Cardiff children (*Brit. Med. Jour., 1907, No. 2404, pp. 226, 227*).—A summary of a paper by Walford in which the conclusion is reached that pupils in the elementary schools in Cardiff, Wales, suffer from improper rather than insufficient food. The importance of a controlled milk supply and other hygienic features are discussed with reference to the feeding of school children.

Experiments on nutrition: balance of income and outgo of nitrogen and sodium chlorid, M. LETULLE and MLLE. M. POMPILIAN (*Compt. Rend. Acad. Sci. [Paris], 143 (1906), No. 26, pp. 1188–1191, figs. 4*).—Brief statements are made regarding the experiments on the income and outgo of nitrogen and sodium chlorid made with the respiration calorimeter previously described (E. S. R., 18, p. 962). In general, the quantities of both substances eliminated were found to vary with the individual characteristics of the subject, but equilibrium was possible under proper conditions. During fasting the excretion of nitrogen diminishes. When food is taken after fasting the tissues undergo repair. Nitrogen and chlorin equilibrium are reached after oscillations in the excretion.

The influence of flesh eating on endurance, I. FISHER (*Separate from Yale Med. Jour., 1907, Mar., pp. 16*).—Endurance tests were made with flesh eaters and flesh abstainers, which, in the absence of more satisfactory mechanical methods of measurement, included holding the arms horizontally as long as possible, deep knee bending, and leg raising by the subject lying on his back. The results reported, according to the author, "would indicate that the users of low-proteid and the nonflesh dietaries have far greater endurance than those who are accustomed to the ordinary American diet."

"Of the three groups compared, the large flesh eaters showed far less endurance than the abstainers, even when the latter were leading a sedentary life. . . . It is possible that the superiority of the abstainers is due to the absence of flesh foods or to the use of a similar amount of proteid, or to both as well as to the abstention from tea, coffee, and condiments."

With 14 flesh abstainers the average daily nitrogen excretion ranged from 0.095 to 0.15 gm. per kilogram body weight.

The factors of safety in animal structure and animal economy, S. J. MELTZER (*Jour. Amer. Med. Assoc., 48 (1907), No. 8, pp. 655–664; Science, n. ser., 25 (1907), No. 639, pp. 481–498*).—Engines, bridges, etc., are ordinarily constructed so that they possess a strength or capacity in excess of the usual or average demands made upon them, and the author has summarized and discussed a large amount of physiological and other data to determine whether similarly the human body possesses factors of safety, the question as a whole being considered especially in its relation to food requirements and the possible effect of an excess of proteid foods. With the possible exception of the reproductive organs and nerve ganglia, the author concludes that the body is well provided with factors of safety.

"All organs of the body are built on the plan of superabundance of structures and energy. Of the supplies of energy to the animal we see that oxygen is luxuriously supplied. The supply of carbohydrates and fats is apparently large enough even to keep up a steady luxurious surplus. For the supply of proteid we find in the actual conditions of life that man and beast, if they can afford, provide themselves with quantities which physiological chemists call liberal. This may or may not be the quantity which nature requires and approves of. Experiments have shown that a number of men subsisted on the half of such quantities. This latter might be an indispensable minimum, just as there is an indispensable minimum for all other luxuriously endowed provisions of the animal organism, and the liberal ingestion of proteid might be another instance of the principle of abundance ruling the structures and energies of the animal body. There is, however, a theory that in just this single instance the minimum is meant by nature to be also the optimum. But it is a theory for the support of which there is not a single fact. On the contrary, some facts seem to indicate that nature meant differently. Such facts are, for instance, the abundance of proteolytic enzyms in the digestive canal and the great capacity of the canal for absorption of proteids. Such luxurious provision for digestion and absorption of proteids is fair evidence that nature expects the organism to make liberal use of them. Then there is a fact that proteid material is stored away for use in emergencies, just as carbohydrates and fats are stored away. . . . The storing away of proteid, like the storing away of glycogen and fat, for use in expected and unexpected exceptional conditions, is exactly like the superabundance of tissue in an organ of an animal, or like an extra beam in the support of a building or a bridge—a factor of safety."

The author believes, therefore, that "with regard to the function of supply of tissue and energy by means of proteid food nature meant it should be governed by the same principle of affluence which governs the entire construction of the animal for the safety of its life and the perpetuation of its species."

Concerning the extractives of muscle. VI, The identity of ignotin and carnosin, W. Gulewitsch (*Ztschr. Physiol. Chem., 50 (1906), No. 2–3, pp. 204–208*).—The investigations reported showed the identity of ignotin and carnosin, and according to the author the name of "ignotin" should be dropped.

Protein metabolism when carbohydrates are taken, J. E. Johansson and W. Hellgren (*Upsala Läkarefor. Forhandl., n. ser., 11 (1906), Sup. VII, pp. 9*).—Experiments with a man who was engaged in light muscular work showed that neither carbohydrates nor fat, when added to the diet, diminished the excretion of nitrogen. On the other hand, if the protein consumption was increased an increase in nitrogen was noted in 2 hours.

On the excretion of nitrogen, creatinin, and uric acid in fever, J. B. Leathes (*Jour. Physiol., 35, 1907*). *No. 3, pp. 205–214, figs. 2*).—In the experiments reported, the increased nitrogen metabolism which was observed accompanying fever, "was found to involve an increased output of both creatinin and uric acid, as well as of total nitrogen. But the increased output was most marked in the case of uric acid and least marked in the case of creatinin."

On the elimination of sulphocyanates from the blood, and their supposed formation in the salivary glands, D. H. de Souza (*Jour. Physiol., 35 (1907), No. 4, pp. 332–345*).—According to the author's investigations, "sulphocyanates in the food are readily absorbed and remain as such in the body for a considerable time. . . .

"In only one doubtful case [of the experiments reported], then, was there anything to show that sulphocyanates are formed in the salivary glands. In fact the evidence leads one to conclude that this substance is not a specific secretion of the salivary glands, but merely a waste product in the blood which is turned out by the salivary and other glands, together with and in a proportional concentration to the other salts of the secretions."

Draft of a model State pure food and drug law, M. N. Kline (*Amer. Jour. Pharm., 79 (1907), No. 2, pp. 74–78*).—This draft of a pure food and drug law was suggested by the chairman of the committee on legislation of the National Wholesale Druggists' Association.

Food inspection decisions, H. W. Wiley, F. L. Dunlap, and G. P. McCabe (*U. S. Dept. Agr., Food Insp. Decisions 69, pp. 3; 70–72, pp. 4; 73, pp. 2*).—The topics covered by these decisions are the inspection of food and drugs and the identification of inspectors, the abuse of the guaranty for advertising purposes, the labeling of succotash, the use of guaranties and serial numbers thereof, and the interstate transportation of imported meats and meat food products.

According to the decision rendered as to succotash, this word, if used without qualification, is understood to imply that the product designated is composed of green sweet corn and green beans. If soaked beans or soaked corn are used the fact must be declared in the proper manner.

ANIMAL PRODUCTION.

Protein in vetch hay, A. L. Knisely (*Oregon Sta. Rpt. 1905, pp. 59–65*).—Continuing earlier work (E. S. R., 16, p. 801), the protein content of vetch was studied, the work extending over 3 years. Samples were cut at the proper stage for hay making, cured, and analyzed. The average results are summarized in the table which follows:

Protein content of vetch hay, water-free material.

Year	Number of analyses	Maximum protein found.	Minimum protein found.	Average protein found.
		Per cent.	*Per cent.*	*Per cent.*
Sample taken 1903	10	21.31	11.63	17.39
Sample taken 1904	80	23.31	12.19	18.03
Sample taken 1905	152	25.52	9.65	18.85

These results show that there has been, thus far, a steady increase in the percentage of protein in the vetch hay. Two or 3 samples of this year's crop ran extremely low in protein, while many samples contained over 20 and a few, more than 25 per cent protein. All determinations were made either in duplicate or triplicate, corrections being made according to blank determinations.

Early work of the station on the digestibility of vetch hay is cited (E. S. R., 17, p. 65).

Relative values of feeding stuffs, H. P. Armsby (*Pennsylvania Sta. Bul. 71, rev. ed., pp. 16*).—The results reported for clover hay in the first edition of the bulletin (E. S. R., 17, p. 380) were suspected of being too low, a suspicion which later experiments confirmed. This revision contains the corrected results.

Prickly pear and other cacti as food for stock, II, D. Griffiths and R. F. Hare (*New Mexico Sta. Bul. 60, pp. 135, pls. 7, figs. 2, folding tables 7*).—This bulletin reports 187 proximate analyses and 26 ash analyses of samples of different sorts of cacti collected from central Texas to California and southward to the central plateau of Mexico.

In general the analyses show that the cacti may be said to compare favorably with ordinary green fodders and root crops. The apparently high protein and fat content in the fruit of some species is due, as the authors point out, to the large proportion of these nutrients found in the seed. As the seeds are surrounded by a dense layer of indigestible tissue, the high values for protein and fat are misleading. "The analyses show that the fodder value of the fruit of cholla (*Opuntia fulgida*) and related species investigated is little more than that of the stems."

"There are many points of special interest in connection with the ash analyses, especially the high content of potash, magnesium, and calcium. Although the cane cacti show a relatively higher food value, practical considerations relating to growth and ease of propagation render them of less value than the prickly pear, except in certain limited localities where they are especially abundant."

The bulletin contains a brief summary of literature regarding the feeding value of cacti and a general discussion of the importance of these plants as feeding stuffs in arid regions.

Concentrated feeding stuffs, J. P. Street, J. W. Kellogg, and V. J. Carberry (*New Jersey Stas. Bul. 201, pp. 46*).—Under the State feeding-stuff law 471 samples were analyzed, of which 304 belonged to the class that required a guarantee.

The goods analyzed included cotton-seed meal, linseed meal, gluten meal and feed, corn bran and similar goods, hominy meal and feed, distillers' grains, malt sprouts, dried brewers' grains, molasses feeds, proprietary mixed feeds, alfalfa meal, barley feed, curled cocoanut fiber, dried beet pulp, beef biscuit, proprietary poultry feeds, meat meal, beef scraps and similar goods, wheat bran, feeding flour, wheat middlings, wheat feed, ground wheat, wheat and rye bran, rye bran, rye feed, rye middlings, ground rye, corn meal, corn and cob meal, ground oats, ground corn and oats, ground mixed grains, buckwheat middlings, buckwheat bran, and buckwheat feed.

"Of the 160 different brands of feed received, and which should have been guaranteed, 2 failed to meet this requirement.

"Of the 304 samples which were guaranteed, 77 were deficient, 53 of these being low in protein.

"Of the 167 samples which did not require a guarantee, all were pure products, but the wheat brans and feeding flours were below normal quality; one sample each of wheat middlings, rye middlings and rye bran were misbranded.

"No direct adulteration is reported, but the inferiority of cotton-seed meal this year, and the poor quality of certain molasses grains and alfalfa meals, are worthy of notice.

"Certain feeds of good quality still bear guarantees higher than their composition warrants.

"The variability in composition of certain high-grade feeds and the absence of a corresponding variation in selling price demands that a strict regard must be given to the prices asked, as well as to the amount of nutrients guaranteed.

"The cheapest protein feeds this year were buckwheat middlings, malt sprouts, dried brewers' grains, high-grade distillers' grains, and cotton-seed meal."

Analyses of feeding stuffs and mineral and spring waters, A. L. Knisely (*Oregon Sta. Rpt. 1905, pp. 69–72*).—Analyses are reported of western wild oats (*Avena fatua*) at different stages of growth, alfalfa, blue clover (*Melilotus cœrulea*), mill feed, oat chop, dairy chop, gluten feed, wheat bran, prepared cattle food, and several varieties of barley. A number of mineral and spring waters were also analyzed. The percentage composition of wild oats in proper condition for hay making was water 61.11, protein 2.72, fat (ether extract) 1.58, nitrogen-free extract 22.61, crude fiber 9.20, and ash 2.78 per cent. The percentage composition of blue clover was water 11.63, protein 19.17, fat 2.07, nitrogen-free extract 36.71, crude fiber 22.44, and ash 7.98 per cent.

Judged by the analytical data, "wild oats are considerably richer than average timothy hay, nearly as rich as Kentucky blue grass or redtop, and compare favorably with orchard grass and ordinary oat hay. . . . The so-called blue clover is a plant exceedingly rich in protein."

Grape marc and its utilization for feeding farm animals, E. Bertainchand (*Bul. Dir. Agr. et Com. [Tunis], 10 (1906), No. 4, pp. 527–529*).—Analyses are reported of different sorts of grape marc and its value as a feeding stuff is favorably spoken of.

Utilization of grape by-products: Dried grape marc, L. Roos (*Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), No. 7, pp. 197–200*).—A summary of data on the feeding value of grape marc. Analytical and other data are quoted.

Tests of the relative feeding value of dried beet chips, "sugar chips," and dried beet leaves carried on with steers and sheep, W. Schneidewind (*Landw. Wchnschr. Sachsen., 8 (1906), No. 51, pp. 406–410*).—The data summarized regarding the feeding value of dried beet chips, dried "sugar chips," and dried beet tops in tests with steers and sheep indicate that the dried beet forage is the least economical and the "sugar chips" the most economical of these feeding stuffs.

The digestibility of rice feed meal rich in fat, O. Kellner and L. Lepoutre (*Landw. Vers. Stat., 65 (1907), No. 5–6, pp. 463–465*).—In experiments with sheep it was found that rice meal rich in fat had the following coefficients of digestibility: Dry matter 70.2, protein 64.4, fat 82.9, nitrogen-free extract 81.8, and crude fiber 24 per cent.

Additional information concerning the feeding stuff control law, A. Goss and W. J. Jones, Jr. (*Indiana Sta. Circ. 7, pp. 14.*)—This circular, which supplements a previous publication (E. S. R., 18, p. 1073), gives information of interest especially to manufacturers and dealers regarding the proper way to make a declaration respecting a feed, the use of labels and tags, and similar matters.

Stock feeding, J. Michels (*South Carolina Sta. Bul. 128, pp. 24, fig. 1*).—A general discussion of the principles and practice of the feeding of dairy cattle, pig feeding, and silos and silage with special reference to local conditions.

Experiments in animal nutrition, W. P. Gamble (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 74–87*).—A summary and discussion of animal feeding precedes a report of the results of experiments with sheep and steers on the digestibility of a number of feeding stuffs, particularly of the by-products of flour and cereal meals. The average results which were obtained follow:

Average digestibility of a number of feeding stuffs.

Kind of feeding stuff.	Kind of animal.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.
		Per cent.	*Per cent.*	*Per cent.*	*Per cent.*
Oat hulls	Steer	51.39	92.13	83.81	59.10
Oat dust, average 2 trials	Sheep	68.15	79.01	69.51	[a]34.48
Oat dust	Steers	64.90	73.51	61.07	30.14
Corn meal, average 2 trials	Steers	80.63	92.60	88.72	89.26
Corn bran	Steers	52.24	67.17	68.19	25.75
Clover hay	Sheep	70.08	52.32	66.43	31.19
North feed	Steers	73.02	91.23	79.21	72.04
Mill feed	Steers	55.26	66.95	72.28	48.99
Green corn fodder	Steers	68.25	85.31	78.59	87.12
Field cured corn	Steers	35.89	83.85	85.85	71.29
Corn silage	Steers	56.81	61.69	74.88	74.25
Oat straw	Steers	36.81	74.99	70.27	41.73
Mixed chop	Steers	73.27	49.63	69.44	51.04
Brewers' grains	Steers	77.34	95.28	72.88	52.[illegible]
Barley dust, average 2 trials	Steers	60.15	73.36	54.64	3[illegible].24
Ground oats	Steers	66.83	97.20	81.09	[illegible].22
Dried molasses beet pulp	Steers	65.59	9.45	78.56	[illegible]03
Wheat bran	Steers	75.18	66.47	74.[illegible]	[illegible]
Pea bran, average 2 trials	Sheep	66.15	80.89	77.[illegible]	[illegible]

[a] One test only.

The feeding value of beet pulp is discussed at length and data from a variety of sources summarized. Analyses of fermented and unfermented beet pulp and the whole beet are reported, as well as analyses of a number of commercial feeding stuffs, including among other materials ground barley, wild oats, crushed peas, pea meal, malt combings, ground screenings, and mixed feeds. The need of a Canadian feeding-stuff law is pointed out.

Fattening steers for export, G. E. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 158–163*).—Two lots of 11 steers each and one lot of 7 steers were used to test the relative merits of long and short feeding periods. The ration in every case consisted of mixed grain with hay, silage, and roots.

On a heavy grain ration, on an average 0.607 lb. per 100 lbs. of live weight per day, the average daily gain per head in the short period, 60 days, was 1.61 lbs. and the cost of a pound of gain 9.59 cts. On a light grain ration, 0.566 lb. per 100 lbs. of live weight per day, the average daily gain was 1.5 lbs. per head and the cost of a pound of gain 9.09 cts. In the long period, 153 days, the average daily gain was 1.62 lbs. per head, the cost of a pound of gain 8.47 cts., and the average grain consumption 0.489 lb. per 100 lbs. of live weight per day. The steers fed for the longer time were at the beginning of the test on an average 200 to 400 lbs. lighter than the others.

The following deductions were drawn from the test, although the results are not regarded as final: "To feed steers cheaply, the meal ration should be kept as low as possible consistent with securing a reasonable gain in weight. Heavy, fleshy (short keep) steers may be fed a heavier meal ration per 100 lbs. live weight than lighter and thinner steers, and give an equal profit, making allowance for their greater first cost per pound. The lighter and thinner the steers, the greater the need for economizing in regard to the meal ration. Condition being equal, heavy steers are worth more per pound to buy as feeders than lighter ones, the selling price per pound being the same. Weight being equal, a fleshy steer is worth more per pound to buy as a feeder, the selling price per pound being the same. The lighter and thinner the steer the greater the 'spread' between the buying and selling price per pound necessary to compensate the man who feeds him."

The relative merits of feeding steers loose and tied in stalls were tested with the 2 lots which were fed for the short period. The 11 steers fed the light ration were tied and 4 of the steers which were fed the heavy ration were allowed to run loose. In the case of the latter animals the average daily gain was 2.31 lbs. per steer and the cost of a pound of gain 6.34 cts. "It will be noticed that the loose steers made a much greater gain than those kept tied and at a much smaller cost per pound. . . . No doubt much of this advantage was due to the fact that the loose steers suffered no setback from scouring." The author points out that the difference in favor of the profit with the loose steers would have been still greater if they had been of the same weight as the animals fed tied instead of being lighter.

Feeding tests, F. W. TAYLOR (*New Hampshire Sta. Bul. 129, pp. 255–257*).—In a 60-day test, the relative value of protena was studied in comparison with a mixture of equal parts of bran, corn meal, cottonseed meal, linseed meal, and [illegible] Grains. Two Jersey cows in approximately the same period of lactation [illegible]ed 8 lbs. per head per day of the grain rations, together with mixed hay [illegible]. On the protena ration, the total milk production was 1,048.2 qts., [illegible] to 146.36 lbs. of butter, and on the mixed ration, 1,211 qts., equivalent [illegible]4 lbs. of butter.

[illegible]st per quart of milk produced was 1.19 cents for the protena and 1.10 [illegible] the mixed ration. The protena, which is made up largely of ground [illegible] more or less dusty and forms a sticky paste in the mouth, and for that [illegible]s not eaten with the same relish as the variety ration."

[illegible]eding value of protena was further tested with 5 pigs. On this material [illegible] milk there was a total gain of 151 lbs. in 30 days, at a cost of 3.27

cents per pound. "The bulky nature of the protena had a distending effect on the pigs' stomachs and induced a rapid and healthy growth."

A test was also made to determine to what extent silage can replace grain in the winter feeding of dairy cows, but final conclusions were not drawn. "It has already been found, however, that the flow of milk is lessened as the amount of grain is reduced and is not fully restored as the amount of silage is increased. The exact data regarding cost of rations, quality of milk, and condition and healthfulness of the animals are not ready for publication."

Brief statements are made regarding the station poultry plant and sheep breeding tests which it is planned to undertake.

The feeding value of spelt [emmer] in beef and pork production, J. W. Wilson and H. G. Skinner (*South Dakota Sta. Bul. 100, pp. 119–128, fig. 1*).—Three lots of 4 steers each and 1 lot of 3 steers were used in a test covering 170 days, undertaken to compare shelled corn, whole and ground emmer, or, as it is called here, spelt, and shelled corn and spelt 1 : 1, prairie hay being fed in addition to the grain in every case. The average daily gain per head ranged from 1.54 lbs. on the ground spelt to 2.38 lbs. on shelled corn. The shelled-corn lot required the smallest amount of grain per pound of gain, 8.48 lbs., and made gains at the least cost, 7.4 cts. per pound. The largest amount of grain per pound of gain, 10.60 lbs., was noted with the lot fed whole spelt. Gain was most expensive on ground spelt, costing 9.3 cts. per pound.

"This test shows that a pound of corn is equal to 1.25 lbs. of spelt for steer feeding. It also shows that where the corn and spelt were mixed half and half by weight the relation is about the same, with a small increase in gain in favor of the mixture."

From data obtained in earlier experiments with corn and the results noted in a 44-day supplementary period with pigs on whole and ground spelt, and on spelt and corn the authors estimated the total gains made by the 2 lots of 2 pigs while following each lot of steers. These values ranged from 56 lbs. in the case of ground spelt to 188 lbs. in the case of corn. The smallest amount of extra grain, 129 lbs., was fed to the last-mentioned lot and the largest quantity, 941 lbs., to the first-mentioned lot. "These results show that there is very little feed for swine when following steers fed on ground spelt."

Spelt with the husks and the husks alone were analyzed. The authors call attention to the fact that the husk contains the greater part of the crude fiber and that when ground the grain separates from the husk.

The fattening of calves for veal, J. Porter (*Jour. Bd. Agr.* [*London*], *13* (*1907*), *No. 12, pp. 727–731*).—On the basis of personal experience, the various questions connected with the profitable fattening of calves on whole milk are considered. In an instance cited, a calf fed whole milk for 4 weeks made a total gain of 70 lbs. A calf thus fed should, according to the author, receive not over 16 lbs. of milk per day at the end of the first week and this should be increased to not over 30 lbs. per day at the end of the fourth week of feeding.

"Probably a month is as long as it is advisable to feed calves on whole milk on a dairy farm, or until they have reached about 160 lbs. live weight or 96 lbs. of veal. This weight may be attained in a month, provided the calves are fatted as quickly as possible; but one can not expect to do it unless the calves are fed three times a day. An effort should also be made to have the calves fat at the time veal commands a high price; otherwise the returns from vealing calves on whole milk may not be at all satisfactory."

Cost of wintering yearlings, F. W. Taylor (*New Hampshire Sta. Bul. 129, p. 248*).—The cost of wintering for 5.5 months 4 lots of 2 heifers each on a ration of bran and corn-meal alone and supplemented by linseed meal, gluten feed, and cotton-seed meal, ranged from $19.28 on the linseed-meal ration to

$20.95 on the cotton-seed meal ration. The heifers fed the linseed-meal ration were in better condition than the others.

[Pig feeding], G. E. Day (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 151–158*).—From records which have been kept at the station with a considerable number of pigs, the author calculates that the cost of feed from birth to weaning is $3.91 per litter, the average live weight when marketed 176 lbs. per pig, the cost of feed per pound of live weight from birth to market condition 4.2 cts., and the average total cost per pound, including service fee and maintenance of dry sow, 4.61 cts.

The data gathered at the station were supplemented by the results of coöperative investigations carried on by 10 farmers according to instructions. As shown by the data for 95 pigs, the average age of weaning was 52 days, the average age at which pigs were marketed 214 days, and the average live weight when marketed 200 lbs.

The cost of raising pork is calculated on the basis of meal at different values, ranging from $20 to $23 per ton. At the higher value and estimating that the pigs cost $1.50 each at weaning time the average cost of a pound was 4.49 cts., and estimating that the pigs cost $2.50 each at weaning time it was 4.99 cts.

"That the average cost per pound should be within 5 cts., when meal is valued at $23 per ton, and the pigs at $2.50 each when weaned, is much beyond our expectations.

"We regard $20 per ton a fair valuation of meal when the grain is home grown, as it includes much that is not marketable. Even when much of the feed has to be bought, we believe that, with a little foresight, the meal bill can be kept well under $22 per ton. If the farmer buys injudiciously, or uses unnecessarily high-priced foods, he should not blame the pigs.

"These experiments show cheaper average gains than were obtained in our own work, but most of these experiments represent summer feeding, whereas most of our feeding was done during the winter."

Relative value of shelled corn and corn meal for fattening pigs, W. A. Henry and D. H. Otis (*Wisconsin Sta. Bul. 145, pp. 16, fig. 1*).—Noted from another publication (E. S. R., 18, p. 1074).

Experiments on the utilization of betain by ruminants (sheep), W. Völtz (*Arch. Physiol. [Pflüger], 116 (1907), No. 5–6, pp. 307–333*).—From the investigations reported the conclusion was drawn that there is not the slightest reason to consider betain a nitrogenous nutrient. On the other hand, it is very probable that it causes harm when taken in large doses even in a very soluble form.

Light and heavy oats for horses, F. W. Taylor (*New Hampshire Sta. Bul. 129, pp. 248–251*).—The comparative value of light and heavy oats was studied with 3 pairs of work horses of Percheron blood, 1 animal in each lot being fed heavy oats for 30 days and the others the light oats. During an additional period of 30 days the conditions were reversed. In all cases 16 lbs. of oats were fed each day with mixed hay of average quality ad libitum. All the horses performed farm labor requiring average exertion and endurance.

As shown by weighings taken twice a week, 1 horse lost on both light and heavy oats, 5 gained on heavy oats, and 4 gained on light oats. "The total gain or loss in any case was not material and was not much greater than the variation in weight from one day to another. The practical results of this experiment seem to indicate that, pound for pound, the light oats have nearly the same feeding value as the heavy oats. Although the heavy oats contain a higher percentage of protein, fat, and nitrogen-free extract, and a less percentage of fiber than the light oats, it seems probable that the relative proportions of these constituents in the two grades are such that they are more easily and thorougly digested. . . . The percentage of kernel, as would be expected, bears a close relation to the weight per bushel. It should be remembered that although the two grades are practically equal, pound for pound, they are not equal, quart for quart, and that in feeding by measure, as is usually done, due allowance should be made for the heavy oats and a less quantity given. Since oats are bought and sold by weight instead of measure there seems to be no gain made in buying the heavy oats at a much advanced price over the light oats." The oats used were analyzed.

Mule raising at Poitou, H. Raquet (*Ann. Gembloux, 17* (*1907*), *No. 1, pp. 19–32, figs. 4*).—The care and management of asses, breeding of mules, and related questions are considered.

Poultry management, G. A. Bell (*U. S. Dept. Agr., Farmers' Bul. 287, pp. 48, figs. 14*).—This bulletin is condensed from an article on general poultry management previously noted (E. S. R., 18, p. 1158) and deals exclusively with the chicken industry.

[Poultry], W. R. Graham (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32* (*1906*), *pp. 201–210, fig. 1*).—Data regarding the class-room work in poultry, new poultry buildings, and the general plan of poultry feeding followed at the station are given, as well as the results of a number of tests.

In a study of egg evaporation in relation to incubation it was found that the average evaporation of eggs hatched by hens in nests out of doors was 10.9 per cent, of eggs hatched in nests on moist earth and kept indoors 11.9 per cent, in nests containing chaff and kept indoors 15.15 per cent, and in an indoor nest lined with rubber cloth 10.9 per cent. Eighty-seven per cent of the fertile eggs hatched in the out-of-door nests on an average, while with the indoor nests the range was from 77 per cent in the chaff nests to 100 per cent in the nests lined with rubber cloth.

With eggs hatched in incubators the evaporation of hatched eggs ranged from 9.1 to 16.3 per cent of their original weight and the percentage of fertile eggs which hatched in the different incubators from 64.9 to 76.3. Considering both natural and artificial methods the evaporation of individual eggs which hatched ranged from 5.9 to 27 per cent.

Data are also reported regarding the evaporation and the number of chickens which hatched in the case of eggs laid by the same hen. In the author's opinion it is preferable in artificial incubation to keep the evaporation of the eggs about the same as that noted with hens out of doors on the ground. "It appears to me that this is nearer nature, and the chicks so hatched did well in the majority of hatches. There was a large per cent of carbonic-acid gas under the hens in the air around the eggs. The temperature of the air was about 101° F., and the relative humidity was somewhat less than the air in the room."

When late-hatched chicks were fed from a hopper wheat with some cracked corn and a little other feed also and kept in a cornfield where they were allowed to run loose after the first day, very satisfactory gains in weight were noted. "The corn field was considerable distance from the plant and no water was near by; hence we made no pretense to water the chicks." The author states that he would not at present advocate not watering chicks, but mentions this fact in connection with the conditions under which the chicks were raised. When 26 days old such chicks averaged 8.5 oz. in weight, while those in the poultry run averaged 3.25 oz. When 8 weeks old the average weights were 2 lbs. and 10.6 oz., respectively, and when 4 months old cockerels raised in the cornfield weighed 5 lbs. each.

In the author's opinion, a cultivated hoe crop and hopper feeding are worthy of serious consideration when one wishes to grow the best chickens with the least trouble. "One hen laid in 20 days after being put out with chicks. Nearly all the hens laid in reasonable time and their plumage was glossy."

The value of different feed mixtures, some of which contained molasses, was tested in a 2 weeks' period with 9 lots of 12 birds each. The greatest gain, 15.5 lbs. per lot, was noted on a ration of shredded wheat and corn meal 1:1 mixed with molasses and sour milk, and the smallest gain, 6 lbs. per lot, on bread and sour milk. With this lot the cost of a pound of gain was 9.58 cts., the highest value noted, while with the first mentioned lot it was 5.04 cts., the lowest value noted.

When different rations for fleshing chickens were tested with 5 lots of 12 birds each for a week, the greatest gain, 9 lbs. per lot, was found with the chickens fed shredded wheat, corn meal, and oatmeal 1:1:1 with sour milk, and the gain was also most cheaply made with this lot, costing 3.38 cts. per pound. The smallest gain, 6.5 lbs. per lot, was noted with the lot fed shredded wheat mixed with whey. The gain was most expensive with the lot fed shredded wheat and corn meal 1:1 with molasses and sour milk, costing 5.98 cts. per pound.

"It will be noticed that a mixture of grain gave better results than any single food. We have had similar results in previous years, and generally speaking I would recommend a mixed ration in preference to one composed of any single grain.

"Molasses has not so far proved to be an economical food as to cost or number of pounds of gain produced. It also appeared to induce feather pulling.

"Whey did not give as good results as milk, yet is a food worth considering. This year's tests and last year's tests [E. S. R., 17, p. 177] both indicate that whey has considerable value.

"Shredded wheat made a better showing than either bread or ground wheat. The chickens fed on bread soon tire of the ration and in one instance developed indigestion. Ground wheat was relished better for the entire period of feeding than was shredded wheat, but did not make as economical gains."

Several rations were tested in which weed seeds formed half or all of the grain ration. The birds absolutely refused to eat these rations with the exception of one which was made up of refuse shredded wheat biscuit and weed seeds 1:1 mixed with milk.

To determine whether weed seeds could be used as a feeding stuff despite the fact that the hens did not like them, a test was made in which such seeds mixed with water were fed with a cramming machine. The recorded data show that the chickens lost weight.

"The results were that the birds appeared to be unable to digest the food. Apparently there are some seeds which are indigestible, so far as chickens are concerned. If the crops were moderately well filled it would take almost 36 hours to empty them; so that we found to feed them twice a day we could give but very small quantities. The food did not seem to satisfy the birds at all; or, in other words, when they were put back in the coops they would whine and be constantly looking for something to eat. They acted as if they were starving to death. In fact, after feeding 1 week we found it necessary, in order to save the birds' lives, to change the method of feeding entirely."

Some data are also recorded regarding the gains made after the weed seed period and also by birds fed shredded wheat and weed seeds.

In a test of the gains made by ducks of different varieties it was found that in 9 weeks Pekin ducks made an average gain of 4.6 lbs. and Cayugas 4.17 lbs., and in 8 weeks Indian Runners 3.21 lbs. per head. The grain required per pound of gain in the 3 cases was 2.6, 3.12, and 3 lbs., respectively. All the lots were fed alike "a mash composed of 4 parts corn meal, 3 parts oatmeal, 1 part shorts, to which was added 25 per cent meat meal. The mash was mixed with cold water. Sprouted wheat and bread and milk were fed once daily, being last fed at night. The ducks were fed 4 times daily until 6 weeks of age, then 3 times daily."

Brief statements are also made regarding the domestic and wild geese raised at the station.

Alfalfa for chickens and ducks, W. M. SAWYER (*Breeder's Gaz., 51 (1907), No. 15, p. 848, figs. 2*).—On the basis of personal experience the author recommends alfalfa for chicken and duck feeding, and briefly discusses the care and management of ducks and related questions.

"Always catch ducks by the neck to lift them around, and carry them by catching hold of the butts of their wings or by holding them around the body. If caught by the legs they are easily sprained and sometimes broken."

Locusts for fowls (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 1, p. 8*).—A brief note in which the value of dried locusts for poultry is spoken of on the basis of personal experience. A liberal supply, it is said, can be fed to young ducks and chickens with advantage.

Turtle raising in Japan (*Trans-Pacific Trade, 1 (1907), No. 1, p. 6*).—The raising of turtles for food under artificial conditions in Japan is described.

DAIRY FARMING—DAIRYING.

Report of the professor of dairy husbandry, H. H. DEAN (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 90–132, figs. 2*).—Results of experiments in butter making, cheese making, determining moisture in dairy products, and milk testing, as well as work along other dairy lines, are presented in this report. Many of the experiments are in continuation of previous work (E. S. R., 17, p. 903).

Experiments in butter making (pp. 91–108).—Butter was made from sweet pasteurized cream with and without the addition of a starter and from ripened cream. Incidentally tests were made of several butter preservatives. The butter was made during the months of June, July, and August, and shipped to Montreal, where it was scored and then forwarded to London, where it was again scored.

Some of the conclusions reached are as follows: The sweet cream was churned in less time than the ripened cream. The buttermilk from the sweet cream contained more fat than the buttermilk from the ripened cream. The moisture content of the butter was fairly constant, averaging 13.79 per cent. Unsalted butter received the highest scores both in Montreal and London. There was little or no difference in the quality of the butter made from the different lots of cream, neither was the quality affected apparently by the preservative used. Borax gave as good results as any of the preservatives tried. Butter made from gathered cream was as good as that made from cream separated at the factory.

In 63 experiments, tests were made of various methods of churning as regards their effect upon the moisture in butter. It was found that the overrun would vary considerably from day to day when the same method of churning was followed as closely as possible. "However, after summing up the whole question and averaging all the results there would appear to be an increased 'overrun' as a result of massing the butter in the buttermilk, or washing the butter in comparatively warm water with the rollers of the combined churn and worker in motion." The percentages of moisture, curd, and salt did not bear a constant relation to the percentage of overrun. "So far as the quality of the butter is indicated by the results in scoring there was not much difference from the various methods followed, showing that a butter maker may vary his methods considerably from what are regarded as standard rules and still be able to make a good quality of butter. However, the tendency was for 'mottled' and 'gritty' butter when the butter was massed in either the buttermilk or the wash water. The tendency was toward 'greasy' butter when it was washed in water at too high a temperature or with the rollers in motion."

Experiments in cheese making (pp. 108–119).—Rennet and pepsin for coagulating milk in cheese making were again compared. "As a result of 3 years' work comparing rennet and pepsin as agents for coagulating milk, we are not prepared to recommend pepsin in preference to rennet, chiefly because the pepsin is more difficult to prepare for addition to the milk, and there appears to be no advantage in yield or quality of cheese as a result of using the pepsin."

Comparative tests were again made of using rennet at the rate of 3⅜ and 6¾ oz. per 1,000 lbs. of milk. As in previous years, the yield of cheese was slightly greater when double the usual quantity of rennet was used. There was little difference in shrinkage or in the quality of the cheese. The extra rennet apparently hastened the ripening process.

The results of experiments in cooking the curd at different temperatures were in favor of a temperature between 98° and 100° F. Only in special cases such as overripe milk is it considered advisable to use a higher temperature.

While the moisture in the curd at the time of dipping averaged 52.49 per cent in one series and 47.81 in another, the difference in the moisture of the green cheese was less than 0.5 per cent. The acidity developed faster in the curd with the excessive moisture and the yield of cheese was slightly higher. The quality of the cheese was apparently unaffected by the amount of the moisture in the curd at the time of dipping.

Further experiments were made in regard to the acidity of the curd at the time of salting. The development of 0.1 per cent more acid before salting decreased slightly the yield of marketable cheese, but tended to improve the quality.

Additional experiments in ripening cheese at different temperatures confirmed previous conclusions that the lower the temperature the less the shrinkage and the better the quality of the cheese. The results indicate that cheese may safely be transferred directly from the press to a room having a temperature of about 40° F.

Another year's work in ripening cheese on shelves as compared with boxing directly from the press confirms the previous conclusion that it is quite practicable to put cheese into a clean dry box and place in cold storage at 40°.

Determining moisture in butter, curd, and cheese (pp. 120–125).—The author outlines methods of determining moisture in dairy products by drying in an oven and also describes a rapid method devised by him for determining moisture in curd at the time of dipping. The method is based upon the assumption that the specific gravity of a given volume of curd varies approximately according to the water content of the curd.

"For obtaining comparatively uniform percentages of moisture in the curds at dipping, we suggest to cheese makers that they try the specific gravity or weight plan. The results of our work seem to indicate that if a given volume of curd weighs slightly less than 1 gm. for each cubic centimeter of curd packed closely into a cylindrical vessel, it will contain about the proper degree of moisture at the time of dipping. The results further show that for each increase or decrease of 0.1 gm. in weight, which 17.5 cc. of curd may vary, the moisture increases or decreases by about 0.6 per cent."

Milk and cream testing (pp. 125–130).—In 18 tests the differences in the reading of the Babcock test of measured and weighed samples of cream varied from 0 to 1.5 per cent.

Comparative tests were made of the Babcock and Gerber methods. The differences with milk testing from 3 to 5 per cent rarely exceeded 0.1 per cent.

Notes are given on the official tests of Holstein cows made during the year.

Dairy herd record (pp. 130–132).—Records are given of the dairy herd of 19 cows for 1 year. The yield of individual cows ranged from 11,499 lbs. of milk to 3,952 lbs., and the profit on milk over cost of feed from $1.39 to $36.99.

Investigations on the influence of food fat upon the milk production of cows, O. KELLNER (*Illus. Landw. Ztg., 27 (1907), Nos. 43, pp. 387, 388; 44, pp. 397–399; Molk. Ztg., 21 (1907), No. 25, pp. 687–690*).—At the instigation of the association of agricultural experiment stations in Germany and under the authority of the German government, 10 agricultural institutions conducted experiments on a uniform plan to determine the influence of rations rich and poor in fat upon the yield and composition of milk. The general results are summarized in these articles.

Five institutions employed the period system and 5 the group system of feeding, both methods giving practically the same results. Twenty cows were used in each experiment. The rations compared contained the same amounts of digestible matter, but one was richer in carbohydrates and the other richer in fat. The digestible fat in the 2 rations was, respectively, 0.4 to 0.5 and 0.9 to 1 kg. per 1,000 kg. live weight.

The principal result of the experiments was to the effect that the substitution of fat for the equivalent amount of carbohydrates was not only of no advantage but as a rule was unfavorable as regards both the yield of milk and fat.

In general the percentage of fat in the milk varied inversely as the yield of milk. The properties of the butter fat were appreciably affected by feeding the ration rich in fat, and it is, therefore, possible that in this way the quality of the butter might at times be improved profitably. Aside from this and some other exceptional uses it is not considered desirable to increase the fat in rations in place of the less expensive carbohydrates.

Investigations on the influence of feeding on the milk secretion of cows, W. VON KNIERIEM and A. BUSCHMANN (*Landw. Jahrb., 36 (1907), No. 2, pp. 185–265*).—In the first of 2 series of experiments made with a herd of 55 cows, the authors studied the influence of feeding cocoanut cake, dried brewers' grains, and wheat bran on the yield and composition of milk and on the composition of the butter fat. In the second series similar studies were made with cocoanut cake, linseed cake, and rape-seed cake.

Feeding large quantities of cocoanut cake appeared to increase the fat content of the milk, while brewers' grains apparently reduced the fat content as compared with wheat bran. The constants of the butter fat were materially affected by the character of the rations fed.

In the second series of experiments the milk of 3 cows fed cocoanut cake showed a progressive increase in the percentage of total solids and fat. Linseed cake and rape-seed cake did not give as satisfactory results. Variations in proteids and fat-free solids were small in all instances. The butter fat showed considerable variations in the saponification and iodin numbers. The melting point remained constant.

Aseptic milking, V. WILLEM (*Bul. Agr. [Brussels], 23 (1907), No. 5, pp. 350–375*).—The author discusses quite fully various efforts which have been made to prevent or lessen the usual bacterial contamination of milk during the process of milking, referring particularly to the experiments of Backhaus, von Freudenreich, von Behring, and to those conducted by himself in collaboration with Miele (E. S. R., 17, p. 179).

Milk drawn by the author's method contained on an average 102 bacteria per cubic centimeter after being kept at low temperatures for 39 hours. The milk remained sweet for 10 to 20 days at temperatures of 13 to 15° C. The author also examined 29 samples of mixed milk from 4 or 5 cows, the milk being obtained during August and September under strict aseptic precautions and kept at a temperature of 20 to 24°. At the time of milking the number of bacteria per cubic centimeter varied from 11 to 55 and after 24 hours from 7 to 128. The milk remained sweet for 8 to 30 days.

The results of observations made by the author in dairies in Germany and Switzerland relating to cleanliness in milking are incorporated in the article.

Official tests of dairy cows, 1905-6, F. W. WOLL and R. T. HARRIS (*Wisconsin Sta. Bul. 144, pp. 65, figs. 20*).—During the year the station conducted 922 tests of cows, the results of which are reported in full in this bulletin. The number of cows tested was 315, of which the Holsteins numbered 219, the Guernseys 76, the Jerseys 15, and grades 5.

The station has arranged for a system of semiofficial yearly records to be secured by testing each cow for 2 successive days each month during the year. Results of a considerable number of such tests are reported. Photographs of some of the best cows tested during the year are reproduced in the bulletin and the rules governing the dairy tests are appended.

Bitter milk, TRILLAT and SAUTON (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 17, pp. 926-929*).—According to the experimental results reported by the authors, bitter milk may be produced by yeasts and bacteria capable of forming simultaneously both aldehydes and ammonia. Several yeasts isolated from cheese when inoculated with an ammonia-forming bacillus, produced in milk about 0.4 per cent of aldehydes and 0.2 per cent of ammonia, making the milk very bitter.

Butter fat in milk, T. FARRINGTON (*Jour. Roy. Inst. Pub. Health, 15 (1907), No. 5, pp. 263-267*).—The author calls attention to an inverse relation existing between the fat content of milk and the volatile acids in the fat, and gives figures showing a seasonal variation—the minimum fat content and the maximum volatile acids occurring in April and May and the maximum fat content and the minimum volatile acids in November. He thinks that this principle may possibly be utilized in deciding upon the genuineness of samples of milk having low percentages of fat.

A new method for preventing char in the Babcock centrifugal determination of fat in milk and milk products, M. L. HOLM (*Amer. Food Jour., 2 (1907), No. 7, p. 28*).—After the sample is measured or weighed into the test bottle the author adds 2 cc. of 80 per cent glycerin and then adds the sulphuric acid and centrifuges in the ordinary manner.

Moisture, salt, and curd in butter, R. HARCOURT (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 72, 73*).—In 162 samples of creamery butter made with a view to incorporating a high amount of moisture, the average, maximum, and minimum percentages of water were, respectively, 14.1, 19.92, and 10.34. In 113 samples entered in a butter contest the average, maximum, and minimum percentages of water were, respectively, 12, 15.82, and 9.04. Salt determined in 168 samples from the two lots varied from 0.61 to 5.98 per cent and averaged 2.33 per cent. The proteids in 167 samples calculated by multiplying the nitrogen by the factor 6.38, varied from 0.102 to 0.840 and averaged 0.564 per cent.

Sweet-cream butter (*Canada Dept. Agr., Branch Dairy and Cold Storage Comr. Bul. 13, pp. 15*).—Part 1 of this bulletin by F. T. Shutt and A. T. Charron gives the results of a study of the so-called sweet-cream process of butter making to which particular attention has been called by J. D. Leclair. In this process the cream is pasteurized immediately after separation, cooled, inoculated heavily with a pure culture starter, and churned at once. Detailed data are given for the 3 comparative trials of the sweet cream and ripened cream methods from which the authors conclude that by the sweet-cream process there is no greater loss of butter fat than in the ordinary method with ripened cream, and that the keeping qualities of the butter by the sweet-cream butter are distinctly superior to those of the ripened cream butter.

Part 2 of the bulletin, by J. G. Bouchard, gives directions for the manufacture of butter from sweet or unripened cream.

Standard butter packages (*Dept. Agr. and Tech. Instr. Ireland Jour., 7 (1907), No. 3, pp. 474–488*).—Experiments were conducted for the purpose of ascertaining if boxes of different capacities are required for the same quantity of butter packed during the winter and summer months and for salted and unsalted butters.

From the results obtained it is recommended that boxes should have uniformly a capacity of 1,722 cu. in. and kiels 3,450.5 cu. in. The internal dimensions approved for a box for 56½ lbs. of butter are as follows: Bottom 11 in. square, top. 12 in. square, depth 13 in. The dimensions approved for kiels for 113 lbs. of butter are as follows: Diameter at top and bottom 13⅝ in., diameter at bulge 15¾ in., and depth 19⅝ in.

Coating the interior of butter packages with paraffin is recommended.

Contribution to the knowledge of the action of rennet upon casein, M. VAN HERWERDEN (*Ztschr. Physiol. Chem., 52 (1907), No. 1–2, pp. 184–206*).—The products formed from casein through the action of rennet are designated by the author, paracasein A, paracasein B, and substance C. When the rennet has acted for only a short time the principal product is the paracasein A. This disappears entirely during the prolonged action of the rennet. Paracasein A and B differ in but few of their properties. The substance designated C is a cleavage product of casein and differs from the paracasein in being precipitated by tannic acid and in not reacting with dilute acetic acid, nitric acid, and several other reagents. The properties of the 3 proteids are discussed and summarized in tabular form.

Influence of lactose and lactic acid on the decomposition of casein by micro-organisms, O. LAXA (*Milchw. Zentbl., 3 (1907), No. 5, pp. 200–207*).—The author has studied the action of several species of bacteria and molds upon pure casein as affected by the presence of milk sugar and lactic acid.

The peptonization of casein by certain organisms was very favorably influenced by the lactose but hindered by the lactic acid. The restraining effect of the lactic acid varied greatly with the different organisms but was on the whole more marked with the bacteria than with molds.

Ripening of Edam cheese, F. W. J. BOECKHOUT and J. J. O. DE VRIES (*Rev. Gén. Lait, 6 (1907), No. 11, pp. 248–254, pl. 1*).—In a number of experiments, cheese made from milk obtained with great care to prevent contamination and inoculated with pure cultures of lactic-acid bacteria and a liquefying diplococcus failed to undergo normal ripening. The authors conclude that the liquefying bacteria, which are common in green cheese but which disappear early, do not play any important rôle in the ripening process either directly or by means of enzyms produced by them. They were, moreover, unable to isolate from cheese enzyms capable of liquefying gelatin.

Investigations in the manufacture and curing of cheese. VII, Directions for making the Camembert type of cheese, T. W. Issajeff (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 98, pp. 21, figs. 10*).—This has already been noted from another source (E. S. R., 18, p. 1079).

VETERINARY MEDICINE.

The effect of sunlight upon pathogenic bacteria, R. Wiesner (*Arch. Hyg., 61 (1907), No. 1, pp. 1–102, figs. 16*).—This article is a report upon one of a most elaborate series of investigations regarding the effect of sunlight in attenuating or otherwise influencing pathogenic bacteria. The organisms used in these experiments included *Staphylococcus pyogenes aureus*, the bacilli of diphtheria and typhoid fever, and pathogenic bacteria.

It appears that the number of bacteria in any given mass exposed to the sunlight has no effect upon the length of time during which they live. Differences in resisting power, however, are observed among the different bacteria in a mass of infectious material. From the author's experiments it would appear that the resisting power of pathogenic bacteria toward sunlight increases with the age of the bacteria.

Pathogenic micro-organisms show a greater resisting power toward sunlight in the presence of abundant nutriment than when the nutriment is withheld. All of the rays of the spectrum, including the visible and invisible rays, exercise a bactericidal influence, but the maximum effect is shown by the invisible rays, both at the ultraviolet and ultrared end of the spectrum. The prevailing temperature is also an important factor in determining the effect of sunlight upon bacteria. At an optimum temperature for the growth of bacteria, the rays of the sun exercise the greatest bactericidal effect.

Intestinal resorption of antitoxins, P. H. Römer (*Sitzber. Gesell. Gesam. Naturw. Marburg, 1906, No. 5, pp. 51–60*).—In this paper a report is given on experiments during which quantitative determinations were made of the antitoxin in the milk of cows which had been treated with tetanus antitoxin. The amount of antitoxin in the blood of calves which sucked these cows was also determined. The cows received an antitoxic serum obtained from horses and this serum was secreted in the milk, being also found later in the blood of the calves. In this passage, however, it undergoes a modification, becoming a bovine antitoxin in the place of the equine antitoxin which the cows received.

Government examination of curative sera, R. Otto (*Arb. K. Inst. Expt. Ther. Frankfurt, 1906, No. 2, pp. 86, figs. 8*).—An account is given of the commercial manufacture of antitoxic and antibacterial sera together with historical notes on the development of a method for the government control of these products. The present report contains a detailed discussion of the routine method by which commercial concerns obtain permission to sell their sera under government inspection and also of the methods adopted for this examination.

The official inspector of sera in Germany takes note of their harmlessness and of their power. In order to be considered harmless, sera must be shown to be clear, free from gross precipitates, bacterial contamination, and toxins. Special attention is devoted to the examination and control of diphtheria and tetanus toxins and of the antibacterial sera used for the control of swine erysipelas, swine plague, hog cholera, fowl cholera, and also of tuberculin.

Annual report of the chief State veterinarian, L. Van Es (*Ann. Rpt. State Vet. N. Dak., 1906, pp. 66, pl. 1*).—Copies are given of the detailed reports by the various district veterinarians throughout the State regarding the health of animals in their localities. Brief notes are also given on the prevalence of scabies in sheep, horses, and cattle, *Sclerostomum armatum*, blackleg, rabies, glanders, and tuberculosis.

Recommendations are made regarding methods of stable disinfection. A copy is given of North Dakota laws relating to the control of animal diseases.

Annual report of the veterinary institute, 1906, J. VENNERHOLM (*Årsber. Vet. Inst. [Stockholm], 1906, pp. 105*).—A brief account is given of the veterinary staff of the institute and notes are presented on the occurrence of the more important infectious and other diseases during the year 1906. The prevalence of various diseases is shown in a series of tables.

A comparative study of tubercle bacilli from varied sources, J. R. MOHLER and H. J. WASHBURN (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 96, pp. 88, pls. 6*).—The investigations reported in this bulletin were undertaken for the purpose of repeating the experiments of Smith and Koch regarding the morphological differentiation of different forms of tubercle bacilli. The literature relating to the subject is critically reviewed. The tubercle bacilli used in the experiments were obtained from cattle, sheep, swine, and man. Pure cultures were made on different media and the morphological characters of the different cultures carefully noted. Inoculation experiments were also made on laboratory animals including rabbits, mice, cats, and dogs, and on goats, sheep, and cattle.

In these experiments it appeared that while the growth, morphology, and pathogenesis of both the human and bovine tubercle bacilli are tolerably constant nevertheless differences appear which make it practically impossible to determine the origin of the bacilli from a consideration of the morphology alone. Similarly with the virulence of tubercle bacilli a wide range of variation was observed in cultures obtained both from bovine and human sources. A small proportion of the bacilli obtained from man are highly pathogenic and some of those obtained from cattle and other domestic animals are of very low virulence. The authors found that there is no character possessed by any of the types of tubercle bacilli in one host that may not occasionally be found in another host. In some cases, human tubercle bacilli corresponded strictly to the type of the bacillus in all respects except their very high virulence. It is believed, therefore, that additional evidence has been obtained justifying the enforcement of sanitary measures against the use of milk and meat of tuberculous animals.

The spread of tuberculosis through factory skim milk with suggestions as to its control, H. L. RUSSELL (*Wisconsin Sta. Bul. 143, pp. 28, pl. 1, fig. 1*).—Attention is called to two common methods of infection of dairy herds, viz., by buying tuberculous cattle and by using tuberculous skim milk in feeding calves.

The tuberculin test was applied on a large scale among the cows which furnished the milk for 3 creameries. In making this test it was soon found that many of the mature animals brought in from outside sources were healthy, while the young stock raised on the farms reacted in a large percentage of cases. In the two localities which furnished milk for two of the creameries 1,213 cattle were tested with the result that 374, or about 30 per cent, reacted. Nearly all of the cattle which reacted were raised on the farm and infection doubtless took place through the skim milk which the calves drank. In another locality where the skim milk was apparently not infected with tuberculosis, at least to the same extent, only 8 per cent of the dairy cattle were found to be tuberculous.

Tuberculosis was also observed in hogs and poultry fed on skim milk products. In eliminating this important source of tuberculosis all that is required is the pasteurization of all skim milk. This can best be done by live steam and a required temperature of 176° F. is suggested. It is believed that the pasteurization of skim milk should not be left as a voluntary matter, but should be made compulsory by law.

Some points in the history of the determination of pulmonary tuberculosis from alimentary infection, A. CHAUVEAU (*Rev. Gén. Méd. Vét., 9 (1907), No. 105, pp. 497–510*).—A brief résumé is given of the work of the author and other investigators in which evidence is offered that a considerable percentage at least of the cases of pulmonary tuberculosis arise from infection through the alimentary tract.

The intestinal origin of pulmonary tuberculosis, GAUTIER (*Bul. Soc. Cent. Méd. Vét., 84 (1907), No. 8, pp. 199, 200*).—Attention is called to Vallée's confirmation of von Behring's hypothesis that a large percentage of the cases of pulmonary tuberculosis in animals arise from a primary infection in the alimentary tract. Such has been found to be the case in numerous instances. The alimentary tract may show no lesions at the point where the bacilli entered, but frequent involvement of the mesenteric glands is believed by the author to add weight to the theory.

Tuberculosis of the myocardium, W. VANDERBURG (*Tijdschr. Veeartsenijk., 34 (1907), No. 7, pp. 434–439*).—It is of comparatively rare occurrence that the muscle of the heart is involved in cases of tuberculosis. Brief notes are given on cases of this sort in cattle and horses.

The rôle of alcohol in bovine tuberculosis, SPARTZ (*Bul. Soc. Cent. Méd. Vét., 84 (1907), No. 8, pp. 189, 190*).—Recent experiments have shown almost uniformly that the use of alcohol favors the development of tuberculosis. For obvious reasons this matter has been studied most extensively in man. The author's observations, however, indicate that cows which receive distillery by-products are more susceptible to tuberculosis and are infected in a larger percentage of cases than cattle which do not have these by-products in the ration. In a number of instances herds of cows fed on such products were found to be tuberculous to the extent of 90 to 100 per cent.

The condition of the leucocytes in the presence of encapsuled anthrax bacilli, T. STIENNON (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 13, pp. 646, 647*).—The author's experiments were made on guinea pigs. It appears that anthrax bacilli in capsules are very resistant, and even after being subjected to a temperature of 60° C. for half an hour they are not destroyed by the phagocytes in the peritoneum. Apparently the presence of the capsule protects them from the action of the phagocytes and the exudate in the peritoneum.

Proceedings of a conference of Federal and State representatives to consider plans for the eradication of the cattle tick (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 97, pp. 98*).—A conference was held in Nashville, Tenn., December 5 and 6, 1906, at which representatives of the Bureau of Animal Industry and State authorities interested in the extermination of cattle ticks took part. At this conference the attitude of the Bureau of Animal Industry toward the subject was outlined by A. D. Melvin, and notes on the cooperative work thus far carried on were presented by R. P. Steddom. Such work has been done in nearly all of the Southern States. During the first year of cooperative effort about 549,000 head of cattle have been inspected, and an area of 50,000 sq. miles, covering 45 whole counties and parts of 13 other counties, has been apparently freed from ticks and released from quarantine. These results encourage the belief that with an annual appropriation of $250,000 the cattle tick can be ultimately eradicated.

The legal side of the question was discussed by G. P. McCabe and recommendations made regarding the phraseology of laws intended to permit cooperation between Federal and State authorities. This matter was also referred to by D. F. Luckey. The difficulties met with in the enforcement of quarantine regulations were mentioned by T. Morris, and C. A. Cary called attention to the desirability of giving wide publicity to the work of tick eradication. Reports were received from all of the Southern States regarding the progress of the work.

Methods of eradicating cattle ticks, L. A. KLEIN (*South Carolina Sta. Bul. 130, pp. 17, figs. 3; U. S. Dept. Agr., Bur. Anim. Indus. Circ. 110, pp. 16, figs. 3*).—The desirability of eradicating cattle ticks is set forth in connection with a discussion of the general problems connected with this operation. Cattle ticks should be eradicated for the reasons that they transmit Texas fever, constitute a barrier to interstate traffic in cattle, check the growth and development of all cattle, and prevent to some extent the introduction of a better grade of stock into the South.

It is held that tick eradication is practicable and may be accomplished by a system of rotation of pastures, by the starvation plan, by picking or brushing ticks from the cattle, and by oiling. It is recommended that cattle be examined weekly, beginning about October 15, and treated with crude oil so long as any ticks are found. Under ordinary conditions a thorough application in October will make it unnecessary to give further treatment until March. The oil may be applied with a brush or with a piece of burlap, and all parts of the cow should be covered with it.

East coast fever, J. M. SINCLAIR (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 1, pp. 41–43*).—Notes are given on the prevalence of this disease in Rhodesia. Since 1902 nearly 34,000 cattle have died in Rhodesia from this cause. During the time of its greatest prevalence it was spread largely by the unregulated movement of cattle from place to place, but since quarantine regulations have been established this means of transmission has been eradicated.

Infection with foot-and-mouth disease, C. TERNI (*Clin. Vet. [Milan], 30 (1907), No. 15, pp. 245–254*).—Apparently spontaneous outbreaks of foot-and-mouth disease sometimes occur with more serious symptoms than are manifested in cases which arise by direct contact of healthy cattle with diseased ones. The virus in such cases soon becomes attenuated and incapable of producing an infection except by direct contact. It is believed that in these spontaneous outbreaks the disease is due to the perpetuation of an active virus through the agency of rats.

Gid in calves, P. LEBLANC and FRÉGER (*Jour. Méd. Vét. et Zootech., 58 (1907), Apr., pp. 193–196, fig. 1*).—The comparative infrequency of gid in young calves is believed to be due to the fact that they are kept confined more than lambs and are not attended by dogs. They are therefore less often exposed to infestation from the larvæ of the adult form of the gid worm in dogs.

Treatment of mammitis, SCHULTZE (*Berlin. Tierärztl. Wchnschr., 1906, No. 51, p. 922*).—Contagious mammitis being in most cases due to an invasion of bacteria through the milk canals, the author applied his method of treatment along the same channels. The udder is first thoroughly milked and then cleansed with warm soapsuds and a 3 per cent solution of creolin, after which it is dried. Injections are made into the milk cisterns with solutions containing 5 per cent creolin or camphorated oil. This treatment is repeated 3 times daily and in nearly all cases has brought about prompt improvement.

The etiology of milk fever, E. SONNENBERG (*Berlin. Tierärztl. Wchnschr., 1907, No. 17, pp. 283–286*).—In the study of milk fever undertaken by the author, an attempt was made to determine the effect of the constituents of milk on the physiological functions of experimental animals, particularly rabbits.

From these tests it is concluded that the milk of healthy cows and also of those suffering with milk fever contains proteid substances which produce a typical reaction in rabbits after subcutaneous inoculation. This reaction is shown in the circulatory system and digestive tract. The proteid substances in milk show a chemically toxic effect which persists for only a short time. Apparently the effect is exercised upon the vasomotor nerve center and produces an irritation and paralysis of these structures. According to these experiments, milk fever could be considered as due to an abnormal increase in the quantity of these injurious substances in milk.

The treatment of milk fever, S. R. FERWERDA (*Tijdschr. Veeartsenijk., 34 (1907), No. 7, pp. 444–448*).—Brief notes are presented on the results obtained in the treatment of 160 cases of milk fever by means of air pumped into the udder. In nearly all of these cases marked improvement was observed within a few hours and only 1.3 per cent of the cows died.

The treatment of infectious vaginitis, J. VLASKAMP (*Tijdschr. Veeartsenijk., 34 (1907), No. 7, pp. 439–444*).—The symptoms of infectious vaginitis are briefly described and notes are given on the occurrence and spread of the disease. The author obtained best results in treating the disease from the use of an ointment containing pyoctanin. In these experiments ichthyol was not used, but it is believed that this might also be of some benefit.

Different species of trypanosomata observed in bovines in India, A. LINGARD (*Jour. Trop. Vet. Sci.. 2 (1907), No. 1, pp. 4–50, pls. 3*).—A long series of observations has been made on trypanosomata as found in various bovines in India of the hill and plains types. The species of trypanosomes thus far observed include *T. evansi*, *T. himalayanum*, *T. muktesari*, and *T. indicum* in hill cattle, the last-named species being also found in plains cattle.

The methods of reproduction and other points in the biology of the observed trypanosomes are discussed in detail, and a table is given showing the average measurements of different species.

Observations on some worms found in the aortas of buffaloes and bullocks, G. L. TUCK (*Jour. Trop. Vet. Sci., 2 (1907), No. 1, pp. 69–100*).—Two species of parasitic worms belonging to the family Filariidæ were found, one in the aortic walls of the buffalo and one in domestic cattle. A large percentage of buffalo and cattle was found to be infested with these worms. Each small tumor in the aortic or arterial wall contained a single parasite.

A detailed description is given of the anatomical features of the aorta and of the minute characters of the parasitic worms. The anatomical features of these parasites are shown by way of comparison in tabular form.

Nodules containing larval nematode worms in the intestinal submucosa of a bullock, J. B. CLELAND (*Jour. Trop. Vet. Sci., 2 (1907), No. 1, pp. 67, 68*).—In the course of meat inspection a number of small nodules were found in the submucosa of the small intestine of a beef animal. The nodules were readily movable and appeared to be in close relation with the blood vessel in every case. Each nodule contained 1 or 2 nematode worms which have thus far not been identified.

Trichinosis: A danger in the use of raw pork for food, B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 108, pp. 6, figs. 5*).—The trichina is described in its 3 stages and notes are given on the symptoms of trichinosis in man, its treatment, and the frequency of the occurrence of the disease in man and hogs.

In preventing this disease in man, attention is again called to the fact that no further precaution is necessary than the thorough cooking or preparation of pork before it is eaten. The trichinæ are killed with certainty either by thorough cooking or curing.

The etiology of hog cholera, SCHREIBER (*Berlin. Tierärztl. Wchnschr., 1907, No. 18, pp. 299–301*).—The author has succeeded in producing both the chronic and acute forms of hog cholera by experimental inoculation with pure cultures of *Bacillus suipestifer*. Success was also had in producing an active immunity by means of the hog cholera bacillus and a passive immunity by means of the corresponding serum.

The author takes the position that *B. suipestifer* must be looked upon as the true cause of hog cholera. It is admitted that the filterable virus is capable of producing hog cholera, but the author considers this virus as being a toxin formed by the interaction of the organism and the hog cholera bacillus, and classifies it as an aggressin in the sense of Bail.

Purulent inflammation of the inner ear in hogs, A. M. BERGMAN (*Fortschr Vet. Hyg., 4 (1907), No. 11, pp. 241–243, figs. 3*).—The literature relating to this disease in other animals is briefly mentioned. Apparently no cases had previously been recorded in hogs. The author describes a number of cases in which the head was twisted to one side as the result of the trouble. A microscopic examination of the tissues from the inner ear showed that in the 3 cases thus studied the swine plague bacillus and also *Bacillus pyogenes* were present.

The penetration of dead glanders bacilli through the intestinal wall, J. CANTACUZÈNE (*Compt. Rend. Soc. Biol.* [*Paris*], *61 (1906), No. 37, pp. 618–620*).—Dead glanders bacilli were found capable of passing through the intestinal epithelium. A certain portion of the bacilli after passing through the epithelium were captured by phagocytes, but some of them succeeded in escaping and entering the lymph system. The ordinary intestinal bacteria associated with the dead glanders bacilli were not able to pass by the phagocytes.

Some remarks on equine biliary fever in India, C. H. H. JOLLIFFE (*Jour. Trop. Vet. Sci., 2 (1907), No. 1, pp. 51–66*).—Equine biliary fever prevails quite widely in various parts of India and at times causes serious losses among horses. Notes are given on the symptoms and pathology of these diseases, differential diagnosis, and treatment. Thus far quinin has given the best results in the treatment of the disease, but a really satisfactory treatment has not been devised.

The pathological anatomy of the Borna horse disease, H. OPPENHEIM and R. OSTERTAG (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 2 (1907), No. 2–3, pp. 148–157, figs. 3*).—The pathological lesion in this disease may be characterized as a not diffuse but localized meningocephalitis of an acute but nonpurulent nature. The clinical symptoms and pathological findings are described in detail.

The Trypanosoma equiperdum in Canada, J. G. RUTHERFORD (*Vet. Rec., 19 (1907), No. 982, p. 710*).—It is announced that the protozoan parasite of dourine has been isolated from a case of this disease in Canada and has been recovered from another horse inoculated with material from the first case.

The treatment of infectious cerebro-spinal meningitis of horses, E. DIEM (*Wchnschr. Tierheilk. u. Viehzucht, 51 (1907), No. 16, pp. 301–303*).—In the region about Burghausen it is stated that this disease is quite prevalent. The author has had occasion to treat numerous cases. The treatment recommended is essentially as follows: The horses are kept in well-ventilated, cool stalls and allowed to feed only on grass or hay. An abundant supply of water is provided to which certain mineral salts may be added. On 3 days in succession injections are made of bichlorid of mercury in doses of 0.1 gm. in 10 cc. of water to which a little common salt has been added. This method has been tested for 4 years and in nearly all cases a complete recovery has been brought about.

Inflammatory tumors caused by spiroptera in the horse, WEINBERG (*Compt. Rend. Soc. Biol.* [*Paris*], *62 (1907), No. 7, pp. 287–289*).—A number of nematode worms are known to live as parasites in the stomach of the horse and occasionally they bury themselves in the mucous membrane in such a manner as to produce tumors, with more or less serious effects. This is especially the case with spiroptera. During the formation of the tumors thus produced opportunity is given for infection with pathogenic bacteria,

A study of Babesia canis, K. Kinoshita (*Arch. Protistenk., 8 (1907), No. 2–3, pp. 294–320, pls. 2*).—The various forms assumed by this organism in its different developmental stages are described in detail and the literature of the subject is discussed in connection with a short bibliography. The material was obtained from dogs suffering from spontaneous cases of piroplasmosis or as a result of inoculation.

The decomposition of rabies virus in vitro by means of radium, G. Tizzoni and A. Bongiovanni (*Atti R. Accad. Lincei Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 16 (1907), I, No. 7, pp. 485–492*).—When 20 mg. of bromid of radium were added to 5 cc. of distilled water and 1 cc. of an emulsion of rabies virus was allowed to remain in this solution for 24 hours the virulence of the virus was not reduced in the manner described by Rehn. Negative results were obtained in all instances. The animals inoculated with virus treated with radium died of rabies after the same period of incubation as was shown by control animals.

Rectal vaccination for rabies, P. Remlinger (*Compt. Rend. Soc. Biol.* [*Paris*], *62 (1907), No. 14, pp. 722, 723*).—On account of favorable results obtained from rectal injections of antituberculous serum in the treatment of tuberculosis, the author thought it desirable to test this method of vaccination for rabies. Experiments were carried out on rabbits which received a rabid hemisphere or whole brain in an emulsion of 20 cc. of water at repeated intervals of 1 week. In cases where the mucous membrance was injured to the slightest extent an infection took place in about 1 out of 5 cases. It is found possible, however, to produce an immunity by this method.

A peculiar blood condition, probably parasitic, in Sudanese fowls, A. Balfour (*Jour. Trop. Med. and Hyg.* [*London*], *10 (1907), No. 9, pp. 153–157, figs. 5*).—A disease was noted in fowls which resembles spirillosis in symptoms, the most striking of which were anemia and pronounced stupor. An examination of the blood showed the presence of corpuscles affected with organisms which may prove to be blood parasites. The supposed parasites were found in the blood corpuscles outside of the nucleus in numbers varying from 1 to 7. Gross post-mortem lesions are not striking aside from the general anemia and a congestion of the liver, kidneys, and lungs. The parasites apparently belong to Piroplasma and are believed to be carried by *Argas persicus.*

Quail disease in the United States, G. B. Morse (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 109, pp. 11, figs. 3*).—Quail disease, due to a micro-organism belonging to the group of coli bacillus and characterized by congestion of the lungs, necroses of the liver, and intestinal ulceration, is reported as having occurred in 1906 in Alabama, Kansas, Indian Territory, Virginia, District of Columbia, Massachusetts, and Nova Scotia. The disease affected the common bobwhite, California quail, and other western species of quail and grouse.

The period of incubation appears to be about 10 days. No curative treatment has been devised. Occasionally the disease runs a chronic course but as a rule the birds die within 2 or 3 days, the chief symptoms being dullness and a tendency to remain motionless. The quail disease is recognized as a serious menace to the propagation of these birds. In preventing the spread of the disease, therefore, it is necessary to give close attention to birds kept in captivity and isolate all suspected birds promptly, after which the quarters are to be disinfected.

RURAL ENGINEERING.

Mechanical tests of pumping plants in California, J. N. Le Conte and C. E. Tait (*U. S. Dept. Agr., Office Expt. Stas. Bul. 181, pp. 72, figs. 10*).—This is a report of mechanical tests of pumping plants made as a part of the cooperative irrigation investigations of this Office and the State of California and includes 38 complete tests and more than 100 partial tests, the complete tests showing efficiency and fuel consumption, and the partial tests the work done, fuel consumption, cost of plant, and cost of operation. The power used included gasoline and steam engines and electric motors, and the types of pumps centrifugal, rotary, deep-well, and air-lifts. The efficiencies given are the combined efficiencies of engines, transmission, and pumps, being the ratio between the indicated horsepower and the actual work done in lifting water.

Complete tests were made of 9 plants with gasoline engines running centrifugal pumps, and 2 plants with gasoline engines running deep-well pumps. The efficiencies of the centrifugal-pump plants varied from 20 to 49 per cent, the average being 34 per cent. With the deep-well pumps the efficiency was 33 per cent in one case and 52 per cent in the other, averaging 43 per cent.

The electrically driven plants tested included 7 centrifugal pumps, 1 screw pump, 2 deep-well pumps, 1 triplex pump, and 1 rotary pump. The efficiencies of the plants were as follows: Centrifugal, from 17 to 55 per cent, averaging 41 per cent; screw pump, 30 per cent; deep-well, 37 and 41 per cent, averaging 39 per cent; triplex 53 per cent, and rotary, two tests of same plant, 54 and 49 per cent, averaging 51.5 per cent

The steam-driven pumps included 7 centrifugal pumps, 2 plunger pumps, and 3 air lifts. All these plants used crude oil for fuel. The plant efficiencies were as follows: Centrifugal, 34 to 60 per cent, averaging 47 per cent; plunger, 93 and 91 per cent, averaging 92 per cent; and air lifts 16 to 18 per cent, averaging 17 per cent. It should be remembered that these are tests of plants in actual operation, and they probably represent very well what may be expected from plants of this type under field conditions. For the plants using centrifugal pumps the plant efficiency does not seem to differ definitely from that for gasoline or electric plants. The plant efficiency of the plunger pumps was much higher than for any other type, while for the air-lift plants it was very much lower.

The amount of crude oil consumed varied from over 0.8 gal. per indicated horsepower hour for the smallest plant to a little over 0.2 gal. for the largest plant. For those using centrifugal pumps the amount of crude oil used per useful water horsepower hour varied from 2.5 gal. for the smallest plant to about 0.5 gal. for the most economical plants. A comparison with gasoline engines of corresponding size showed that at least four times as much crude oil was required when burned under a steam boiler as was needed of gasoline when used in an internal-combustion engine. When steam plants run intermittently considerable fuel is required in getting up steam preparatory to starting the plant, so it is probable that in such cases the actual performance of the plants requires more fuel in proportion to the work done than is shown in the tests.

A comparison of the results obtained with centrifugal pumps using gasoline, electricity, and steam as motive power shows that, at the prevailing prices, to raise 1 acre-foot of water 1 ft. the cost of gasoline varies from 1½ to 5 cts., of electricity, from 4½ to 10 cts., and of crude oil for generating steam from 1½ cts. upward. The total cost, according to the rates used for fixed charges and the figures obtained for attendance and maintenance, of raising 1 acre-foot of water 1 ft. for gasoline plants varies from 4 cts. upward, for electrical plants from 7 to 16 cts., and for steam plants from 4 cts. upward.

In addition to the complete tests discussed above, fuel and water tests were made on plants immediately about the city of Pomona, Cal. In each case the measurements were made showing the work done or water horsepower and the fuel consumed, the results being stated with gasoline in gallons per useful water horsepower hour, with electricity in kilowatts per useful water horsepower hour, and with steam plants using crude oil in gallons per useful water horsepower hour.

Forty-seven plants having gasoline engines running centrifugal pumps varying in size from 1½ in. to 6 in. showed consumptions running from 0.228 gal. to 2.414 gal. per useful water horsepower hour, the largest consumption being with the smallest pump, and being more than ten times as large as the smallest consumption. The average consumption was 0.52 gal. per useful water horsepower hour. This is approximately 0.7 gal. to raise 1 acre-foot of water 1 ft.

There are reported 41 plants having gasoline engines and deep-well pumps. The fuel used per useful water horsepower hour varied from 0.185 gal. to 4.81 gal., the average being 0.563 gal. This equals approximately 0.77 gal. per acre-foot raised 1 ft. This is slightly higher than the consumption with centrifugal pumps.

Thirty electrically driven plants were tested, 17 having centrifugal pumps and 13 having deep-well pumps. The power used per useful water horsepower with centrifugal pumps ranged from 1.36 to 3.19 kilowatts, averaging 2.12 kilowatts; with deep-well pumps it ranged from 1.11 to 2.05 kilowatts, averaging 1.5 kilowatts. The advantage in this case is with the deep-well pumps, while with the gasoline engines there was a slight advantage with the centrifugal pumps.

Eleven steam-driven plants were tested, 3 having centrifugal pumps and 8 having air lifts, the average consumption of oil per useful water horsepower hour with the centrifugal pumps being 1.74 gal. and with the air lifts 1.59 gal., the advantage being with the air lifts.

The most striking point shown by the tables is the extreme variation in fuel consumption between the most economical and the most wasteful plants of the same type. As already noted, the highest consumption in the gasoline plants was more than ten times the lowest while the average was but little more than one-fifth of the highest consumption and slightly more than twice the lowest, indicating that proper adjustment and care might on the average reduce the fuel consumed by one-half.

The report gives also a large amount of data regarding the cost of pumping plants and the cost of attendance and repairs, and other interesting facts regarding pumping water for irrigation.

Mechanical tests of pumps and pumping plants used for irrigation and drainage in Louisiana in 1905 and 1906, W. B. GREGORY (*U. S. Dept. Agr., Office Expt. Stas. Bul. 183, pp. 72, figs. 4*).—The Louisiana tests, like the California tests reported above, show the efficiency of the engines, transmissions, and pumps, and the fuel consumption. With 2 exceptions, the plants tested had steam engines and used crude oil for fuel. Twelve plants had centrifugal pumps and 3 had rotary pumps. The most significant point in the results is the high efficiency of the rotary pumps, one showing 81.7 per cent efficiency, and another 83.3 per cent; the third, however, showed only 30.1 per cent efficiency. The efficiencies of the centrifugal-pump plants ranged from 5 to 68 per cent. The pump showing only 5 per cent efficiency was so badly adjusted that the runner wore a hole through the casing and is not included in the average which follows. The next lowest efficiency was 20.8 per cent, the average for 11 plants being 47 per cent. This is exactly the efficiency found for steam-driven centrifugal pumps in the California tests, the fuel being crude oil in both cases.

In this report fuel consumption is given in pounds. If these are reduced to gallons the oil used per useful water horsepower hour with centrifugal pumps ranges from 0.29 gal. to 3.66 gal., averaging 1.1 gal. The 3 rotary pumps showed a consumption of 0.35 gal., 0.27 gal., and 2.53 gal., the average being 1.06 gal., and the 2 lowest consumptions averaging 0.31 gal. Among all the tests the lowest consumption is with a rotary pump, 0.27 gal., and the next lowest is with a centrifugal pump, 0.29 gal. Here, as in California, the most notable feature is the wide variation with plants of the same type, the highest consumption with centrifugal pumps being 12.5 times the lowest.

The average fuel consumption by the plants tested in Louisiana is lower than the average of the California plants, the steam-driven centrifugal plants in California showing an average consumption of 1.74 gal. per useful water horsepower.

The author interprets his results by assuming plants of different types and figuring first cost and operating expenses, using the results of his tests. The results are also used in making a diagram showing the cost of fuel and the total cost of irrigation per acre under varying conditions.

Drainage conditions of Wisconsin, A. R. WHITSON and E. R. JONES (*Wisconsin Sta. Bul. 146, pp. 47, figs. 15, map 1*).—This bulletin describes briefly the soils of Wisconsin and discusses the fertility and drainage of the marsh and clay lands of the State on the basis of greenhouse and field experiments made on typical soils of each class.

The marsh lands are classified in two groups with regard to fertility and drainage conditions: "First, those of the sandstone and granitic regions, in the central and northern portions of the State; and, second, those of the glaciated limestone region of the eastern and southeastern portions."

The clay soils are divided into six groups: (1) Last glacial clay on limestone, (2) red-clay area, (3) old glacial clay on crystalline rocks, (4) last glacial clay on crystalline rock, (5) old glacial clay on limestone and sandstone, and (6) residual clay limestone.

The marsh soils "must be drained in order to be brought under cultivation and their reclamation therefore adds to the total amount of land under cultivation. There is, however, a large part of the upland clay soils, already under cultivation, with a surface and under drainage which is so poor that they would be greatly benefited by tile drainage."

Under present conditions as to value of land and crops and price of labor, the authors conclude that:

"Reclamation by drainage will make 2,000,000 acres of peat and muck lands in the central and northern part of the State fairly productive lands.

"Drainage of the marsh lands in the southeastern part of the State will make nearly two-thirds of a million acres as valuable as any class of lands in the State.

"The amount of clay lands needing tile drainage and the total benefits derived from such drainage are nearly twice as great as in the case of marsh lands.

"A fair estimate of the amount of land needing drainage, of the cost, and of the benefits above cost is given in the following table:

"Acreage of poorly drained land of each type, together with cost and profit of drainage.

Kind of soil.	Number of acres.	Cost of drainage	Profit above cost.
Peat and muck on sand and granitic area	2,000,000	$10,000,000	$20,000,000
Muck and peat on limestone area	610,000	18,300,000	24,000,000
Clay of last glaciation on limestone	1,500,000	11,250,000	30,000,000
Red clay of Superior and Green Bay region	1,300,000	9,750,000	13,000,000
Old glacial clay on granitic area	1,000,000	11,250,000	15,000,000
Last glacial clay on granitic area	600,000	8,600,000	6,000,000
Old glacial clay on limestone	50,000	350,000	1,000,000
Residual clay on limestone	300,000	2,250,000	5,000,000
Total	7,360,000	66,750,000	114,000,000

"The writers know of no other way in which so great an increase in the productive power of the agricultural lands of Wisconsin can be effected as by drainage."

RURAL ECONOMICS.

Report on the decline in the agricultural population of Great Britain, 1881–1906, R. H. REW (*Bd. Agr. and Fisheries [London], 1906, pp. 143, figs. 2, map 1*).—The census returns of Great Britain for the period 1881–1901 show a decrease of 294,627 agricultural laborers, and the returns from this inquiry, which were secured from 248 correspondents, indicate "that since 1901 there has been some further reduction in the number of men employed on farms, but that the diminution is proceeding at a slower rate than during the 10 or 20 years preceding that date."

The causes assigned for this continuing decline in farm labor are the laying down of arable land to grass, the use of improved machinery, the higher wages and superior social advantages afforded by employment in other industries, a deficiency of satisfactory housing accommodation, the few opportunities for financial advancement, a deficiency of small holdings in some counties, and a lack of money on the part of those who would take up small holdings. On the other hand, encouragement for the future is found in the fact that farmers are adapting themselves to changed conditions by taking up "the cultivation of fruit and vegetables, the rearing of poultry, and other industries of a so-called subsidiary character." This transition is expected to furnish new fields of employment to labor.

A large part of the volume is taken up with a summary of the reports of the correspondents, including their names and addresses. Appendix A gives the census statistical data regarding the number of farmers and laborers, acreage of arable and grass lands, number of cattle and sheep, and number of agricultural holdings in each county of Great Britain for the period under discussion.

The decline in number of agricultural laborers in Great Britain, EVERSLEY (*Jour. Roy. Statis. Soc., 70 (1907), No. 2, pp. 267–319*).—The author discusses the causes of this decline and aims to show what has become of the laborers who have left the farm.

Of 130,000 laborers who have been withdrawn in England and Wales in the 20 years from 1881 to 1901, it is claimed that about 56,000 engaged in intensive gardening, while 74,000 found employment at higher wages in avocations and industries where physical strength is necessary—on the railways, in the rural police, as carmen, and as laborers in towns.

In the author's opinion the remedy for the decline of agricultural laborers lies "in the direction of intense cultivation in connection with small holdings, under the stimulus of ownership, or of security of tenure different from that of yearly tenancy, which is the rule with larger farms under the system of British agriculture." This he believes would give a greater employment of labor on the land and ultimately produce a vigorous and independent rural population.

The scarcity of farm help in Hungary (*Wiener Landw. Ztg., 57 (1907), No. 38, pp. 363, 364*).—This article points out the effects of labor agitation and foreign emigration on rural depopulation in Hungary and outlines the measures adopted by landowners and the government to meet this lack of farm labor.

In brief, the remedies consist in the importation of foreign farm help and the governmental regulation of the relations between landowners and laborers, including penalties for the violation of contracts and means for the better housing of laborers. The latter is regarded as especially likely to stop foreign emigration and cause the ultimate return of the people to the land.

A guide for immigrants and settlers, P. HUNTER ET AL. (*Sydney: Govt., 1906, pp. VIII + 418, pls. 31, figs. 329, map 1*).—This gives a history of the agricultural development of New South Wales, points out its industrial and agricultural possibilities, and gives suggestions to immigrants who intend to engage in agriculture. Information is given regarding the methods of acquiring land and of securing advances by settlers.

Reports on land settlement in Southern Rhodesia, 1906–7, C. D. WISE (*Rpts. Land Settlement So. Rhodesia, 1906–7, pp. 29*).—On the basis of personal observations of the agricultural possibilities of the country, the author recommends a system of land settlement in brief as follows:

The establishment of a central farm by the British South Africa Co. of not less than 5,000 acres to serve as an experimental and training farm for prospective settlers; the allotment of farms to settlers of from 1,000 to 1,500 acres in size with alternate blocks of similar size reserved by the company; the selection of practical farm hands only as settlers; the erection of temporary huts, with a view to the health and social intercourse of the settlers; the encouragement of diversified farming under irrigation wherever feasible; financial aid to farmers in a way to stimulate self-help and independent action; and supervision of the settlers' farms by the company's hired manager, with a view of giving advice where needed.

The recommendations as to advances to settlers are made for the purpose of protecting the company while making repayment as easy as possible.

The agricultural wealth and development of Western Siberia, H. C. CARPENTER (*Amer. Exporter, 60 (1907), No. 1, pp. 3–6, figs. 10*).—This is a description of the area, geological characteristics, mineral resources, and agricultural possibilities of Western Siberia.

Under native or Kirkhiz occupation this vast territory was agriculturally neglected with the exception of the raising of live stock, but in recent years farmers from Russia, Germany, Denmark, Norway, and Sweden have settled there and introduced modern methods of culture and machinery. "Their example has been of great value to the Siberian peasants in teaching methods of up-to-date farming. . . . The American observer is, however, forcibly struck by the comparatively small development that has taken place in this region of unexplored riches and by the marvelous opportunities that await intelligent efforts and capital."

Agriculture in Central Spain, A. A. DE ILERA (*Ann. Gembloux, 17 (1907), No. 4, pp. 196–217, figs. 2, map 1*).—The author describes the geography, climate, river systems, and general agricultural conditions of this region, which embraces more than half of Spain.

Agriculture is confined largely to small farms, which are worked with crude implements. Occasionally farms ranging from 50 to 150 hectares are owned or worked by individuals with modern machinery, but rarely is a farm found of more than 150 hectares. The system of farming on shares is largely practiced. Wages of regular farm hands range from 8¾ to 12¼ francs per week in autumn and winter, and from 10½ to 15¾ in spring. During the harvest season piecework is the general rule when farm hands receive from 125 to 150 francs for six weeks' or two months' work with board included. The fare provided for farm help is said to be excellent. Educational institutions for promoting agriculture are few in number.

To give a new impetus to agriculture in Spain the author recommends reforestation, the construction of irrigation works and the more general practice of irrigating crops, the extension of agricultural instruction especially in the common schools, road improvement, the organization of agricultural credit by means of Raiffeisen or similar banks, and agricultural cooperaton.

Report on the condition of agriculture in East Flanders during 1906 (*Rap. Agr. Flandre-Orientale, 1906, pp. 79*).—This includes statistics on the yields of field crops and fruits, and on horse and cattle breeding, together with notes on the weather conditions affecting agriculture, new methods of culture, agricultural industries and associations, etc.

International cooperative bibliography (*London: International Cooperative Alliance, 1906, pp. XXXVII + 276*).—A list of 5,761 entries on cooperative literature. Agriculture proper has 915 entries and rural credit societies 557 entries—a total of 1,472. This places agriculture in the lead of all other forms of cooperation. France heads the list in respect to cooperation applied to agriculture, Italy in regard to credit cooperation, and the United Kingdom in general subjects and distribution.

Agricultural credit in Germany, W. FAWCETT (*West Indian Bul., 7 (1906), No. 4, pp. 317–323*).—Statistics are presented on the growth of credit societies in Germany, with particular reference to the operations of the Schulze-Delitzsch, Raiffeisen, and other cooperative and state banks. On January 1, 1905, there were 1,595 societies for the purchase of agricultural supplies, 3,062 societies for the manufacture of dairy and other products, and 682 other agricultural societies. The members of these societies secure credit through the Raiffeisen local banks connected with central or district banks. Loans are advanced only for reproductive purposes. The administration of the local banks is honorary, "no salary being paid except a trifling sum to the secretary, and all profits realized go to a reserve fund."

Agriculture in our industries (*U. S. Dept. Agr., Office Sec. Circ. 23, pp. 8*).—A speech delivered by the Secretary of Agriculture at Pittsburg, Pa., April 27, 1907, in which a brief account is given of some of the lines of work of this Department and their practical application in the beet sugar, denatured alcohol, rice, matting, camphor, cotton, and tobacco industries, the control of animal diseases, the maintenance of the nitrogen supply, the purification of water systems, the transportation of perishable crops, and in other ways.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 9 (1907), No. 7, pp. 49–56*).—Statistics on the condition, acreage, and prices of agricultural products in the United States and foreign countries are summarized and discussed.

The yields in German agriculture during the last generation, E. WEHRIEDE (*Landw. Jahrb., 36 (1907), No. 1, pp. 99–184*).—Statistical data with discussion of the number of hectares under cultivation, the yields of the principal field crops, the industrial products of agriculture, the development in animal industry, prices of commercial fertilizers and feeding stuffs, etc., from 1870 to 1904, inclusive. The yields are discussed in relation to the law of diminishing returns in agriculture. A bibliography of German agricultural statistics is appended.

Cereal production in 1906 (*Veroffentl. K. Ung. Ackerb. Min., 1907, No. 6, pp. 21*).—The acreage and yields of wheat, rye, barley, oats, and corn in the various grain-producing countries of the world are tabulated and discussed. In some instances similar data regarding potatoes are included.

Statistics of the most important branches of agriculture in Bohemia for the season of 1905–6 (*Mitt. Statis. Landesamt. Böhmen, 10 (1907), No. 1, pt. 2, pp. 53*).—Statistics of yields and acreage under cereal and other crops, including the extent of fallow land, meadows, and beet-sugar production.

Trade and agriculture of the consular district of Odessa for the year 1906, C. S. SMITH ET AL. (*Diplo. and Cons. Rpts. [London], Ann. Ser., 1907,* *No. 3834, pp. 55*).—Statistical data with discussion of the trade relations, which are largely confined to agricultural products, and include the yields, exports, and imports for the year 1906.

Notes are given on the agrarian question, the operation of the state peasant bank, and the antiquated cropping system of the Russian peasantry. Improved methods of cultivation and a better system of rotation of crops are urged as means of solving the agrarian question and improving the lot of the peasantry. Under the present system of cropping one-third of the cultivated area lies fallow, but if the Russian peasants would adopt the intensive system as practiced in Germany, "they would be able to increase the growing area of their present holdings by something like 30 per cent, equivalent to an increase of 49,500,000 acres."

The price of cereals at St. Étienne during three centuries, M. L. J. Gras (*Ann. Soc. Agr.* [*etc.*] *Loire, 2. ser., 26* (*1906*), *No. 2, pp. 137–154*).—The prices of wheat, rye, and oats to the close of the year 1905 are reported and discussed.

AGRICULTURAL EDUCATION.

The man who works with his hands (*U. S. Dept. Agr., Office Sec. Circ. 24, pp. 14*).—This is the address of President Roosevelt at the semicentennial celebration of the founding of agricultural colleges in the United States, at Lansing, Mich., May 31, 1907 (E. S. R., 18, pp. 906–908).

Proceedings of the twentieth annual convention of the Association of American Agricultural Colleges and Experiment Stations held at Baton Rouge, La., November 14–16, 1906, edited by A. C. True, W. H. Beal, and H. C. White (*U. S. Dept. Agr., Office Expt. Stas. Bul. 184, pp. 132, fig 1*).—An account of this convention has been given (E. S. R., 18, pp. 406–416).

Proceedings of the eleventh annual meeting of the American Association of Farmers' Institute Workers, W. H. Beal and J. Hamilton (*U. S. Dept. Agr., Office Expt. Stas. Bul. 182, pp. 90*).—This includes the usual reports from the different States and Territories, the reports of standing and special committees, and papers and addresses on the work of the Illinois Association of Domestic Science on what the institute can do to improve the rural school, to interest the town and city resident in rural life, and to improve and increase crops and live stock, on cooperation in purchasing supplies and marketing products, on the improvement of county fairs, on the farm home, and on the relation of institutes to other extension work.

Agriculture for the high school, K. L. Hatch (*Wis. Jour. Ed., 39* (*1907*), *No. 4, pp. 155, 156*).—The author suggests four lines of work for a high school course in agriculture of not less than one year, viz, a study of the scientific principles underlying the subject, the application of these principles to economic agriculture, illustrative or laboratory work, and collateral reading.

Exercises in elementary agriculture, D. J. Crosby (*U. S. Dept. Agr., Office Expt. Stas. Bul. 186, pp. 64, figs. 40*).—This is a series of exercises showing what may be done with inexpensive apparatus in teaching elementary agriculture in the better grade of common schools. It is intended as a laboratory aid for the teacher, and presents a series of 54 progressive exercises in plant production, including 23 on the growth, nutrition, and reproduction of plants and 23 on the environment of the plant, besides a series of 8 brief elementary lessons on corn by G. F. Warren. There is also a list of text-books and works of reference suitable for the common school library.

Agricultural education and the farmer's son, A. D. Hall (*Jour. Farmers' Club* [*London*], *1907, Mar., pp. 559–576*).—An address before a farmers' club in which attention is called to some of the difficulties arising from the lack of central direction to agricultural education in England.

Agricultural education of collegiate grade is said to be fairly well provided for, but that of secondary and elementary grade, as carried on by the different county councils, is not symmetrically developed. Answers are given to some of the objections offered to agricultural education, notably to the one that successful farming can not be taught in the college. It is stated that with many men successful farming consists not in clever management of land or stock, but in continually getting the better of their neighbors in a bargain, and if money making is to be the test of good farming, a strong will and a tough conscience are far better equipments than any education or science. The thing most needed " is not so much the actual knowledge acquired during a college training as the scientific habit of mind and the training in exact thinking. . . . This habit of mind shortens the time required to gain experience; the scientifically educated man has his observation quickened and fits the facts he sees into a rational system, so that he makes use of experience much more rapidly than the untrained man."

The methods of teaching are discussed, and in this connection the writer recommends that the courses be made more technical, that less time be spent upon the pure sciences and more upon the science of agriculture. In chemistry, for example, " reduce the range of the curriculum to the minimum necessary for the comprehension of the technical course that follows, but that minimum should be taught with such thoroughness and with such a mixture of practical work on the pupil's part as will give him a feeling for scientific method and a respect for accuracy of working." The teachers of agriculture should not depend so much upon text-books, most of which are antiquated, but should do some research work and come into contact with improved methods of farming. A plea is also made for more attention to a rational system of bookkeeping and for instruction dealing with agricultural implements and machines.

Attention is called to the danger of leading students to dabble in so many related sciences that they lose sight of the more important features of agricultural education. This is largely due, in his opinion, to the general examination for the national diploma, which he characterizes as " the most serious hindrance to the progress of agricultural education our colleges are faced with to-day."

Country life and rural education, C. S. Plumb (*Breeder's Gaz., 51 (1907), No. 14, pp. 789, 790, fig. 1*).—The difficulty of keeping children on the farm is attributed largely to the kind of training they receive in rural schools. The remedies suggested are instruction in nature study and elementary agriculture. The work along this line of A. B. Graham, in Clark Co., Ohio, is described.

How to interest district school pupils in the study of agriculture, Gusty van Roy (*Wis. Jour. Ed., 39 (1907), No. 4, pp. 129–131*).—An account of a teacher's experience in teaching elementary agriculture by the nature-study method.

The Home Gardening Association (*Ann. Rpt. Home Gard. Assoc., 7 (1906), pp. 32, figs. 27*).—A report upon the various activities of this association for 1906, including seed distribution, lectures, school gardens and grounds, flower shows, the exchange garden, neighborhood and ward gardens, the use of vacant lots, and training for gardening.

[Report of] the professor of nature study, S. B. McCready (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 32 (1906), pp. 228–236*).—This report shows satisfactory progress in nature-study work, there having been a total attendance of 78 teachers at the spring, summer, and fall sessions. Special equipment is described.

Very few schools have taken advantage of the liberal offer of the Department of Education for the acquisition of an acre of ground for gardening purposes, so that the formal school garden on the school grounds is practically unknown. The horticultural societies have been quite successful in inducing children to grow flowers at home. In Nova Scotia, however, many of the schools have gardens.

MISCELLANEOUS.

Annual Report of Alaska Stations, 1906 (*Alaska Stas. Rpt. 1906, pp. 75*).—A report of the several lines of work carried on during the year at the Sitka, Copper Center, Rampart, and Kenai Stations. In addition to extensive tests of field and horticultural crops and the collection of meteorological data, articles on which are abstracted elsewhere in this issue, experiments in soil inoculation were carried on and an unsuccessful attempt at bee keeping at Sitka is reported. During the year a herd of 11 Galloway cattle was introduced into the Territory with the object of providing a hardy breed suitable for the conditions and of developing an all-purpose breed from the Galloway. Butter of excellent quality and some very good cheese was made at Kenai.

Nineteenth Annual Report of Kansas Station, 1906 (*Kansas Sta. Rpt. 1906, pp. 29*).—This contains a financial statement for the year ended June 30, 1906, a report of the council including abstracts of bulletins issued during the year, brief summaries of the work of the different departments not reported upon in bulletins, a report on the work of Fort Hays Branch Station, and a statement concerning cooperative experiments with this Department.

The report is also issued in bound form, including, in addition, reprints of the bulletins issued during the year, an index of the report and these bulletins, a subject list of the station publications to date, and reprints of the press bulletins issued during the year.

Fourteenth Annual Report of Minnesota Station, 1906 (*Minnesota Sta. Rpt. 1906, pp. XXII + 361, pls. 2, figs. 299*).—This contains the financial statement for the fiscal year ended June 30, 1906, a list of bulletins published during the year, the report of the director, including summaries of the work of the different divisions and of the northwest and northeast experiment farms, and reprints of Bulletins 93–96.

Seventeenth and Eighteenth Annual Reports of New Hampshire Station, 1905–6 (*New Hampshire Sta. Bul. 129, pp. 231–275*).—This contains the organization list of the station, financial statements for the fiscal years ended June 30, 1905 and 1906, and brief reports of the director and heads of departments, portions of which are abstracted elsewhere in this issue.

Seventeenth Annual Report of Oregon Station, 1905 (*Oregon Sta. Rpt. 1905, pp. 80*).—This includes the financial statement for the fiscal year ended June 30, 1905, and brief reports of the director and heads of departments. Portions of the report of the chemist are noted elsewhere in this issue.

Eighteenth Annual Report of Oregon Station, 1906 (*Oregon Sta. Rpt. 1906, pp. 20*).—This report on the college and station includes a financial statement for the year ended June 30, 1906, and a report of the director on the work and needs of the station.

Accessions to the Department Library, January–March, 1907 (*U. S. Dept. Agr., Library Bul. 63, pp. 64*).

NOTES.

Alabama College and Station.—Recent appointments include Dr. W. E. Hinds, formerly connected with the cotton boll weevil investigations of the Bureau of Entomology of this Department, as professor of entomology and entomologist; J. W. Ridgeway, a graduate of the Mississippi College, as assistant in animal industry; and A. J. Norman, a graduate of the Iowa College, as assistant in horticulture.

Arizona University and Station.—R. W. Clothier, of the Florida University, has accepted an appointment as professor of agriculture to include the farmers' institute work. E. E. Free, assistant chemist in the station, has resigned to accept an appointment in the Bureau of Soils of this Department and is succeeded by Dr. W. H. Ross, of the University of Chicago.

California Station.—E. J. Wickson, who has been acting director for some time, has been chosen director.

Colorado College.—Two-year practical courses in agriculture, domestic science, and horseshoeing are announced in a recent bulletin. These courses are to open November 5 and continue for five months during the winter, when there is no rush of work on the farm.

Connecticut State Station.—E. J. Shanley, assistant chemist, has resigned to accept a position as food chemist in the Bureau of Chemistry of this Department.

Connecticut Storrs College and Station.—The college has received a State appropriation of $50,000 for new greenhouses and a horticultural building. The old greenhouse has been turned over to the station and will be a valuable addition to its equipment.

Florida Station.—An irrigation plant is to be constructed in connection with the horticultural work at a cost of $1,000. H. P. Stuckey has resigned as assistant in agronomy. B. F. Floyd, assistant in botany in the Missouri University and Station, has accepted a position in plant physiology and will devote his time to the study of plant nutrition.

Illinois Station.—C. H. Myers has been appointed assistant in chemistry and plant breeding.

Iowa College.—A. V. Storms, R. E. Drennen, Edith G. Charlton, J. A. King, and W. R. Scott have been added to the extension department of the college.

Kansas College and Station.—A department of bacteriology has been established in charge of W. E. King. H. D. Scudder, assistant in agronomy in the college, has resigned to become professor of agronomy in the Oregon College. In accordance with an act of the legislature at its last session, Director C. W. Burkett has made an extended trip to the wheat-growing regions of Europe with a view to the importation of valuable varieties and their distribution through the agency of the station. Oscar Erf, professor of dairy husbandry, is also in Europe studying the dairy industry. E. A. Popenoe has resigned as professor of entomology and zoology in the college and entomologist in the station, and, as previously noted, has been succeeded by T. J. Headlee, of the New Hampshire College and Station. Arthur L. Peck, a graduate of the Massachusetts College, has been appointed assistant horticulturist in the college and station. He will have charge of the experimental work on vegetables.

Louisiana Stations.—H. R. Fulton, plant pathologist, has resigned to accept a similar position at Pennsylvania State College.

Maine University and Station.—W. D. Hurd, acting dean for the past year, has been made dean of the College of Agriculture. G. M. Gowell, for many years professor of animal industry in the college, will henceforth devote his entire time to the poultry investigations of the station, and is succeeded in the college by P. A. Campbell, now instructor in animal husbandry. Herman Beckenstrater, a graduate of the Wisconsin University, has been elected assistant professor of horticulture, and J. E. McClintock, for the past two years an assistant in the Bureau of Soils of this Department, has been elected supervisor of extension work. A farm cottage, a piggery, and a building for the storage of farm implements are being constructed.

Massachusetts College.—F. S. Cooley has resigned as assistant professor of agriculture to accept the newly created position of supervisor of farmers' institutes in Montana.

Michigan College and Station.—E. E. Bogue, head of the department of forestry in the college, died August 19 at the age of 43 years. Z. P. Metcalf has been appointed assistant in entomology in the college and assistant entomologist in the station.

Minnesota Station.—A department of animal nutrition has been established, in charge of T. L. Haecker as professor of dairy husbandry and of animal nutrition.

Montana College and Station.—V. K. Chestnut, professor of chemistry in the college and chemist in the station, resigned September 1 to accept a position with the Bureau of Chemistry of this Department. He is succeeded in the college by W. M. Cobleigh, the professor of physics, and in the station by Edmund Burke, the assistant chemist. A course in pharmacy is to be established.

New Hampshire Station.—C. S. Spooner, of the Bureau of Entomology of this Department, has been appointed assistant entomologist.

New Jersey Stations.—James W. Kellogg, assistant chemist, has resigned to accept a position in the Pennsylvania department of agriculture in connection with the inspection of feeding stuffs.

New Mexico Station.—A novel attempt is being made to combat the codling moth in Donna Ana County by eliminating its food supply. The conditions this season have been unusually favorable for the experiment, as a severe freeze in April killed practically all the fruit in the county. All the orchards were then given a thorough inspection and any fruit found on the trees was destroyed, thereby effecting, it is hoped, the starvation of the entire second brood. To prevent the reintroduction of the pest, all fruit shipped into the county from other sections is being inspected and destroyed if found wormy.

New York State Station.—W. G. Johnson, of *American Agriculturist*, has been appointed by Governor Hughes a member of the board of control to succeed M. H. Olin, deceased.

North Carolina College.—John Michels, of the South Carolina College and Station, has been appointed associate professor of animal husbandry and dairying, and T. D. Eason, a graduate of that college, has been appointed assistant in botany.

North Dakota College and Station.—F. J. Pritchard, assistant professor of botany in the college and assistant botanist in the station, has resigned, to take up advanced work in plant breeding at Cornell University, and is succeeded by F. J. Seaver, late a fellowship student at Columbia University. T. D. Beckwith, of the Soil Bacteriology and Water Purification Investigations of this Department, has been elected assistant professor of bacteriology and plant pathology, and will be associated with the botanist in special soil investigations at the station.

Ohio University and Station.—The Percheron Horse Society of France has recently presented the university with a bronze figure of a percheron to be used in the annual competition of the department of animal husbandry. The figure will at all times be on exhibition to the visiting public, but each year the student having the highest rank in horse judging is to be regarded as its temporary winner and will have his name inscribed upon it. The figure has a total height of 25 inches and is said to be an especially fine work of art.

C. W. Gay has resigned as associate professor of animal husbandry to accept the newly established professorship of animal husbandry in the Veterinary College of the University of Pennsylvania, and has been succeeded by F. R. Marshall, of the Texas College and Station, who will have the title of professor of animal husbandry. R. H. Williams, a graduate of the Ontario Agricultural College, and who received the degree of M. S. at the Illinois University last June, has been appointed assistant in animal husbandry. J. A. Foord, associate professor of crop production and improvement, has resigned, to accept a similar position at the Massachusetts College.

C. W. Montgomery, of Newark, has been appointed a member of the board of control of the station, vice Alva Agee.

Oklahoma College.—A teachers' correspondence course in agriculture has been established, covering two years of nine months each, the work taken up being essentially that given in the School of Agriculture and Domestic Economy, except as to the practical phases. It is hoped that this course will enable teachers to introduce agriculture into their schools in the near future, as well as to fit them for examination in this subject when this is required, as provided for in the pending constitution.

Oregon College and Station.—C. C. Vincent has been appointed assistant in horticulture in the station. F. E. Edwards, assistant professor of chemistry in the college and assistant chemist in the station, has resigned to accept a position with the California Polytechnic School. C. C. Clark has been appointed horticulturist of the Eastern Oregon Substation at Union.

Pennsylvania College and Station.—G. C. Watson, agriculturist, has been granted a furlough of one year, and is acting as manager of a series of farms near Syracuse. C. L. Penny, of the Delaware Station, has been appointed professor of agricultural chemistry in the college.

Porto Rico Station.—P. L. Gile, of the Missouri Station, has been appointed assistant chemist and has entered upon his duties.

Rhode Island Station.—W. F. Schoppe, a graduate of the University of Maine, has been appointed general assistant, and will take charge of the details of the experiments in poultry feeding. The station is carrying on a number of cooperative field experiments in different parts of the State. These are conducted primarily for the purpose of securing material for use in scientific researches now in progress, but they serve incidentally as an aid to the study of the immediate soil requirements in the respective localities.

Clemson College and Station.—H. W. Barre, a graduate of the college, and a recent recipient of the degree of M. S. from the University of Nebraska, has been elected botanist. C. E. Chambliss, entomologist, has resigned. D. O. Nourse, for several years connected with the Virginia College and Station, has been elected professor of agriculture.

Tennessee Station.—J. E. Hite, J. E. Converse, and W. N. Rudd have been appointed assistants in cooperative experiments at Gallatin, Cookeville, and McMinnville, respectively.

Texas Station.—At the last meeting of the board of control the president of the college, H. H. Harrington, was made director of the station, with J. W. Carson assistant to the director and in charge of the feed control work. W. C. Welborn was elected vice director and agriculturist. J. C. Burns, formerly assistant in animal husbandry in the college and station, was made acting professor and placed in control of the station work in animal husbandry, vice F. R. Marshall, who, as noted elsewhere, has gone to Ohio State University.

Utah College and Station.—Dr. A. S. Condon, of Ogden, and J. W. N. Whitecotton, of Provo, have been appointed to the board of trustees, of which L. N. Stohl has been elected president. A college course in veterinary science is to be offered for the first time. The work in agriculture has been increased and the course divided, degrees now being offered in agronomy and arid farming, horticulture and entomology, irrigation and drainage, and animal industry and dairying. A cooperative arrangement has been entered into with the University of Utah whereby a course in irrigation engineering will be offered jointly by the two institutions. The practical and agricultural work will be given by the college and the technical engineering subjects by the university. A normal course in agriculture and domestic science is to be established in a similar manner.

In the station, Robert Stewart has been advanced from assistant chemist to chemist. J. C. Hogenson has been appointed agronomist and E. G. Titus, of the Bureau of Entomology of this Department, associate entomologist. James Dryden, poultryman, has resigned to accept a position with the Oregon Station, and G. M. Turpin, who has been associated with him, will continue the experiments as assistant poultryman. C. Larsen, dairyman, has accepted a position with the South Dakota College.

Virginia College and Station.—A. P. Spencer, a graduate of the college and formerly connected with the station, has been appointed assistant in animal husbandry. T. L. Watson has resigned as consulting geologist.

Washington Station.—According to a note in *Northwestern Horticulturist*, R. S. Northrop, of the Utah College and Station, has been appointed superintendent of the Puyallup substation. This substation has been closed since 1903, but, as previously noted, was reestablished by the last legislature.

Wyoming University and Station.—L. B. McWethy, instructor in agronomy at the Michigan College, has been appointed agronomist in the station and will also teach agronomy in the university. T. F. McConnell has been appointed experimenter in live stock and instructor in animal husbandry in the university.

National Irrigation Congress.—The fifteenth annual session of the National Irrigation Congress was held in Sacramento, Cal., September 2–7, with over 4,000 delegates and visitors in attendance. Vice-President Fairbanks, Senators Perkins, of California, and Newlands, of Nevada, the governors of six States, representatives from China, Germany, and Mexico, E. H. Harriman, and Luther Burbank were among the speakers. The general topic for discussion was the conservation of the national resources. Most of the Federal bureaus engaged in such work were represented and presented outlines of their respective duties.

An address by Gifford Pinchot, of the Forest Service of this Department, dealt especially with the timber supply, and gave estimates showing the probable exhaustion of the present stumpage in thirty-three years. The conservation of soils was discussed by W J McGee, of the Bureau of Soils, that of the mineral resources by J. A. Holmes, of the Geological Survey, and that of the water resources by M. O. Leighton, of the Geological Survey.

F. H. Newell, Director of the Reclamation Service, summarized the work of that service, stating that the expenditures to date had been $33,000,000. The amount available for the next year would be about $7,000,000, which would exhaust the accumulated fund. From that time the service must depend on its current income. Few of the larger projects are completed, and the plan is to get a portion of the land under each reclaimed as soon as possible, and then, with the revenue derived from this part, to build the remainder of the works and finish the reclamation of the entire area.

The work of this Office in irrigation and drainage was outlined in a paper by A. C. True, who was unable to be present. The irrigation work was explained as dealing with the use of water, rather than the construction of works to supply water, and as including the study of the best methods of irrigation throughout the arid region, the feasibility of irrigation in connection with the farming of the semiarid plains, and the profitableness of irrigation in the humid East, where truck and fruit crops of high value are often injured by droughts of short duration. The drainage work consists in formulating and demonstrating the best methods of removing surplus water and protecting land from overflow. Plans for the improvement of more than 2,000,000 acres were made during the past year.

Elwood Mead discussed the necessity for laws providing for definite titles to water rights, in order that the canal owner may have the same security as the landowner; and F. W. Roeding gave an account of the irrigation extension work on the semiarid plains in connection with the three demonstration farms established by the Office.

S. Fortier declared the greatest need of the arid region to be industrious white settlers. He showed that during the year 1908 5,000,000 acres of unimproved lands provided with water rights will be opened for settlement, besides those in Colorado, Montana, Kansas, Nebraska, Oklahoma, and Texas. Before any harvest can be obtained on this new land an average of $20 per acre, or $100,000,000, must be expended. Most of the settlers for this land must come from regions where irrigation is not practiced, and this large expenditure is likely to be lost unless it can be wisely directed. To meet this demand, Professor Fortier recommended the employment by the Government of sufficient skilled irrigation farmers to direct the work of the new settlers.

Among the resolutions adopted by the congress were a recommendation for the reorganization of the irrigation and drainage investigations of this Office as a separate bureau, in recognition of its importance, and an indorsement of the work of the Bureau of Soils, the Forest Service, and the Reclamation Service.

American Chemical Society.—The thirty-sixth general meeting of this organization was held at Toronto June 27–29, with about 150 delegates and visitors in attendance. During the session an excursion was made to the Ontario Agricultural College and Experimental Farm at Guelph. Among the addresses delivered before the general assembly was one on Chemistry and Canadian Agriculture, by F. T. Shutt, chairman of the section on agricultural, sanitary, and biological chemistry. Papers were presented to this section on Unification of Terms Used in Reporting Analytical Results, by C. G. Hopkins; The Determination of Boric Acid in Common Salt, by W. D. Bigelow and C. S. Brinton; and Solubilities of Food Colors, by E. Gudeman, together with several reported by title only. It was decided to separate the offices of editor and secretary, Prof. W. A. Noyes, now of the University of Illinois, retaining the editorship of the *Journal of the American Chemical Society* and of *Chemical Abstracts*, and Dr. C. L. Parsons, head of the chemical department of the New Hampshire College, becoming secretary.

International Zoological Congress.—The Seventh International Zoological Congress was held in Boston August 19–25, in the new buildings of the Harvard Medical School. Alexander Agassiz presided, and general addresses were delivered by Prof. R. Hertwig, of Munich, on *Neuere Probleme der Zellforschung*, Sir John Murray, of the Challenger Expedition, and Prof. W. K. Brooks, of Johns Hopkins University, on Are Heredity and Variation Facts? Nearly 300 papers and addresses were offered in the various sections. Following the scientific session excursions were conducted during the following two weeks to various scientific and educational institutions in Boston, New York, Philadelphia, Washington, and other points of interest.

International Institute of Agriculture.—According to a recent note in *Science*, forty-four nations, including nearly all of agricultural importance, have now ratified the convention for the creation of this institution. The palace which is being erected for the Institute in the gardens of the Villa Borghese in Rome is rapidly approaching completion. Invitations for the meeting of the permanent committee in charge and for the inauguration of the Institute will probably be issued in November, and with the first meeting of the committee next spring the Institute will enter upon active work.

In the meantime, the Italian Royal Commission has appointed Professor Pantaleoni to superintend an inquiry as to the exact extent of the information which the different countries which have adhered to the convention can supply with regard to their agricultural production. This information will be catalogued and classified in tabular form, and a report, which will also contain comments on the various statistical methods employed, will be ready for the use of the permanent committee, whose first duty will be to discover the amount and reliable character of the statistics already available and to suggest new means of obtaining information where necessary. A great mass of material bearing on this subject has already been received by the *Consulta* from the countries interested.

The Royal Commission has also intrusted Professor Bodio, of the General Bureau of Statistics, with a mission to Germany and Austria in order to study on the spot the systems pursued by those countries for the collection of agricultural reports, and has taken other steps as well in order to extend and improve the statistics furnished in Italy.

New journals.—A Russian journal, entitled *Zhurnal Bolyeznī Rastenii*, has been begun under the editorship of A. A. Elenkin, assisted by a corps of collaborators. It is to be the official organ of the central station of plant pathology at the Imperial Botanical Gardens at St. Petersburg and will appear quarterly. German summaries of original contributions will be given. The first number contains articles on the occurrence of the mildew *Sphærotheca mors-uvæ* on the fruit of gooseberries, the Russian species of dodder, symbiosis, a mite disease of onions due to *Tyroglyphus allii* n. sp., a gall of Pyrethrum, and the first portion of a monograph on the edible and poisonous mushrooms of Russia.

According to *Gardener's Chronicle*, *Finske Tradgardsolare*, a horticultural journal in the Swedish language, has recently been established at Helsingfors, Finland, by a local nurseryman.

Miscellaneous.—The new barns of the Macdonald Agricultural College were struck by lightning September 5 and totally destroyed. The loss is said to be about $50,000.

The Secondary and Agricultural School at Bigods Hall, Dunmow, establisned by Lady Warwick about ten years ago, is to be closed. A lack of cordial support from the local educational committee and the resignation of the head master are among the reasons assigned.

Prof. W. O. Atwater died at Middletown, Conn., September 22, after several years of failing health. An account of his life will be given in the next issue.

Dr. C. A. Browne, jr., in charge of the sugar laboratory in the Bureau of Chemistry, of this Department, has resigned to become chief of the New York

Sugar Trade Laboratory, just established. He will assume his new duties about the middle of October.

C. C. Poindexter, a graduate of Ohio State University, and more recently private secretary to Prof. T. F. Hunt at Cornell University, has been appointed Director of the Department of Agriculture of the American Church Institute for Negroes. He will endeavor to introduce the study of agriculture into the St. Paul Normal and Industrial School, Lawrenceville, Va., and into the St. Augustine School, Raleigh, N. C., and will also give lectures on agricultural economics and rural sociology to the students in the Bishop Payne Divinity School, Petersburg, Va.

O

EXPERIMENT STATION RECORD.

VOL. XIX. OCTOBER, 1907. No. 2.

Professor Wilbur Olin Atwater, of Connecticut, whose death, September 22, 1907, terminated an illness of nearly three years, was for many years a leader in the experiment station movement in the United States. He was born at Johnsburg, New York, May 3, 1844, and received his academic training at the University of Vermont and Wesleyan University, Middletown, Conn., graduating from the latter institution in 1865. He received the degree of doctor of philosophy from Yale University in 1869, after a period principally spent in studying agricultural chemistry under Professor S. W. Johnson. There he also came under the influence of Professor W. H. Brewer. At this time he showed the desire to work in fields of science giving promise of early enlargement, and the ability to forecast correctly the lines of development—characteristics which largely determined his future success.

As part of his work for his doctor's degree he made a considerable number of analyses of several varieties of Indian corn—the first work of the kind done with modern methods on this side of the Atlantic.

From 1869 to 1871 he studied agricultural and physiological chemistry at the Universities of Leipsic and Berlin, and acquainted himself with the European agricultural experiment stations. After his return to America his first experience as a college professor was at the University of Tennessee and the Maine State College. He was thus brought into close touch with the national movement for agricultural education and research.

Coming to Wesleyan University in 1873 as professor of chemistry he was again brought into close association with Professors Johnson and Brewer at New Haven, and with other agricultural leaders in Connecticut. He also became intimate with Orange Judd, the founder and long-time editor of the *American Agriculturist*, who had but recently given to Wesleyan, his alma mater, a hall of natural sciences, in which Professor Atwater had his laboratory for more than thirty years.

With these men as associates and advisers, Professor Atwater, fresh from his observations of the agricultural experiment stations in Europe, entered with enthusiasm into the movement already on foot to establish similar institutions in the United States. On December 17, 1873, at the winter meeting of the Connecticut State Board of Agriculture, Professors Johnson and Atwater urged the establishment of a station in Connecticut after the European pattern. A long period of agitation followed. The project had many warm friends, but the great mass of the farmers took little interest in the enterprise. When it became apparent that it could not otherwise succeed, Mr. Judd offered on his own part $1,000 to begin the undertaking, and on the part of the trustees of Wesleyan University the free use of a chemical laboratory. These offers were made on condition that the State legislature should appropriate $2,000 per annum for two years for the work of the station. An act making this appropriation was unanimously passed July 2, 1875. Professor Atwater was made director and the first State agricultural experiment station began operations in October of that year. At the end of the two years provided for in the original bill the station was reorganized under the direct control of the State and permanently located in New Haven.

Without doubt this action of the State was a great discouragement to Professor Atwater, but with his usual persistency he continued to labor earnestly in the cause of agricultural science. He organized and superintended an extensive series of field experiments with fertilizers, accounts of which were printed in the annual reports of the Connecticut State Board of Agriculture for 1877 and succeeding years. He also prepared a series of about seventy articles on science applied to farming, which were published in the *American Agriculturist* from 1875 to 1881.

As agricultural experiment stations were established one after another in rapid succession in different States he kept in touch with the leaders in this movement, and when it assumed a national aspect and Congress was asked to enact a general law granting funds for stations in all the States he was among the foremost of the representative leaders of agricultural advancement who urged the adoption of this measure.

The report made in 1887 by a committee of the Association of American Agricultural Colleges and Experiment Stations, of which Professor Atwater was chairman, is notable as showing his attitude regarding the character of the work the stations should undertake:

"It is essential that they recognize the immediate demand for things immediately useful; that they find what questions are of direct practical importance and give such questions an amount of early attention which under other circumstances might be disproportionate. But it is vitally important that the highest scientific ideal be maintained and every effort be made toward its realization.

The future usefulness of the stations will depend upon what they discover of permanent value, and this must come largely from the most abstract and profound research; to forget this will be fatal."

On the passage of the Hatch Act in 1887, granting $15,000 annually to each State and Territory for the maintenance of one or more experiment stations, the Storrs Agricultural Experiment Station was organized by an act of the Connecticut legislature and half the income received under the Hatch Act was granted to this station. Professor Atwater was made director and for fourteen years managed this station. During this period a relatively large amount of scientific work along chemical and other lines related to agriculture was done by the station with quite limited funds. Of special interest were his studies on the acquisition of atmospheric nitrogen by plants, begun several years prior to the establishment of the Storrs Station and continued as part of the work of that station from 1888 to 1892.

On the invitation of Commissioner Colman Professor Atwater consented to become the first director of the Office of Experiment Stations, on condition that he should retain the directorship of the Storrs Station and his college professorship. In this capacity, Professor Atwater established in large measure the policy on which the Office has since been conducted and laid down the lines of its future work.

In his first report the following statements were made regarding the functions he deemed proper for this Office:

"The most immediately pressing need seems to be that of a clearing house and an exchange for the stations. The stations are widely separated; they need to know more about each other's work; they need each other's help, especially that which comes from the interchange of experience. Much is gained by the proper distribution of work and by cooperation where that is feasible. As a clearing house this Office can facilitate intercommunication between the stations, collate the results of their work, and facilitate its most advantageous coordination. It can serve as an exchange or distributing point for information in two ways, negotiating between the stations and the agricultural public, on the one side, and between the stations and the world of science, on the other.

"One of the means by which this Department can mediate between the stations and the agricultural public is the issuing of a series of farmers' bulletins, which should collate the results of station work bearing upon special topics, and the teachings of other research, and put the whole into a form so plain that the intelligent farmer will understand it, so brief that he will read it through, and so practical that he will take it to heart. Thus, while each station is distributing its own results to the farmer of its own State, this instrumentality will help to make the several stations serviceable to the agriculture of the whole country.

"As a mediator between the stations and the world of science this branch of the Department should be in a condition to collate the results of experimental research in this country and in Europe, and publish them in convenient form for the use of the station workers and others interested in the science of agriculture.

"One need is a journal for the stations, to contain accounts of their current research, abstracts of similar work in this and in other countries, and other matters of mutual interest.

"Information is also greatly needed in regard to past work and its results. This would be probably best brought to the stations in the form of monographs on special subjects."

The first Farmers' Bulletin was published in 1889. This series proved so popular that it was soon transferred from the Office and made a general series for the Department of Agriculture. Congress made a special printing fund for these bulletins and the Congressmen undertook their distribution on a large scale. Some three hundred of these bulletins have been issued, a large number of which were prepared in the Office of Experiment Stations. The editions of many have aggregated hundreds of thousands of copies, and the total output of Farmers' Bulletins by the Department has been many millions of copies. In 1906 alone more than 7,500,000 copies were printed.

The abstract journal was provided in the *Experiment Station Record*, the first volume of which appeared in 1889. This has been developed into the most comprehensive journal of its class in existence, and its circulation among students and investigators in agricultural science is world-wide. The Office has also published a considerable number of monographs on special subjects, as suggested by Professor Atwater.

With the rapid growth of the experiment station movement at home and abroad and the recognized success of the Office as a promoter of the stations' interests, the business of this Office soon increased to such an extent that it became obvious that it should have at its head a Chief who could devote his entire time to its management. Unwilling to relinquish his work as a teacher and investigator, Professor Atwater decided to give up the directorship of the Office in 1891. He continued, however, to have official relations with the Office to the end of his active career.

The influence of Professor Atwater on the development of agricultural education and research in this country has been greatly broadened through the men who came into direct association with him as students in his laboratory and who have since become directors of experiment stations and professors in the agricultural colleges.

Some of these men are now among the most active and influential leaders in this national movement.

Parallel with his studies in agricultural chemistry, Professor Atwater began at an early day to carry on investigations in physiological chemistry, with special reference to the problems of human nutrition. These studies soon brought him into official relations with national and State organizations having funds which could be used to promote research in these lines. Between 1879 and 1883 he made a series of analyses of fish for the U. S. Fish Commission and of the flesh of domestic animals for the Smithsonian Institution. Studies of the dietaries of people in Massachusetts and Canada were also made for the Massachusetts Bureau of Statistics and Labor and published in 1886.

Similar work was instituted in connection with the Storrs Experiment Station, and in 1893 with the aid of Hon. J. Sterling Morton, then Secretary of Agriculture, an appropriation was obtained from Congress for investigations in human nutrition in cooperation with the experiment stations. Headquarters for this enterprise were established at Middletown, Conn., and Professor Atwater was made its official chief. This work was broadly planned and steadily developed in succeeding years, until it became the most comprehensive investigation on this subject ever undertaken. The cooperation of universities, colleges, and schools, experiment stations, public institutions, and private organizations of various kinds was secured in different parts of the country. Hundreds of dietary studies of people of different occupations were made and the results of similar studies throughout the world were collated. Numerous digestion experiments with men were carried on and special studies made of the nutritive value of different cereals, meats, vegetables, fruits, and nuts, the effects of cooking and other forms of preparation on nutritive value, and other important food problems. Special efforts were made to improve methods and apparatus for such work.

From a scientific point of view, the most important result of these investigations was the development and use by Professor Atwater and his associates of special forms of bomb and respiration calorimeters. An instrument was thus provided for studying the effect of food in the development of energy, which surpasses all apparatus of the kind in range and accuracy of operation. As a direct outcome of this work, a respiration calorimeter for use with the larger domestic animals has been constructed by Doctor Armsby at State College, Pa. The studies in human nutrition already made with the Atwater-Rosa-Benedict calorimeter have been very important and promise to be still more so. Direct evidence has been obtained that the law of the conservation of energy holds good in the utilization of food in the human body, as well as important data regarding the actual nutritive value of different foods and the relations of food to muscular energy and mental work.

As the Chief of Nutrition Investigations in the Office of Experiment Stations, Professor Atwater planned and supervised investigations which were carried on in about twenty States. The results of this work are embodied in about one hundred technical and popular publications issued by this Department and the Storrs Experiment Station.

These publications have had a wide distribution and have been extensively utilized in domestic science courses in colleges and schools throughout the country and in the preparation of text-books and manuals on human nutrition in this and other countries.

In the judgment of competent experts, the nutrition investigations conducted under Professor Atwater's direction were more thorough in their scientific methods, more extended in the scope and amount of investigation, and more useful in the distribution and practical application of their results than any other inquiry of the kind ever undertaken in this country or in Europe.

As a public official working in a wide way in the organization and management of enterprises for the general good, Professor Atwater has earned the lasting gratitude of his countrymen, especially by what he did in connection with the agricultural experiment stations and the nutrition investigations. To this work he brought a well-trained mind and a true scientific purpose. He had the enthusiasm and persistence necessary to impress other men with the importance of his enterprises and to carry him successfully over periods of opposition and discouragement. He had unusual ability in the conception and formulation of broad lines of work, and in attracting and holding men competent to give him such aid as he needed to complete these plans, put them into successful operation, and secure substantial results.

The observance by the Massachusetts Agricultural College of its fortieth anniversary by means of a four-day conference on rural progress was a novel and suggestive departure of considerable general interest. While, as may be seen by reference to the program as given elsewhere in this issue, the historical and anniversary aspects of the occasion received substantial recognition, the opportunity was utilized in the main as a means of bringing together the varied forces making for rural betterment—educational, social, and religious, as well as those distinctively agricultural. The cooperation of existing organizations such as the State Board of Agriculture, the State Grange, and local associations of workers in schools, churches, and libraries was invited, and the program was so arranged as to offer not only sessions at which the special phases of immediate interest to each of these bodies could be considered, but also an opportunity for all to come in touch with questions of general significance.

Although the attendance at some of the sessions was less representative than had been expected, much interest was developed, especially among people but indirectly associated with agriculture and to whom the agricultural college had hitherto apparently seemed to make little appeal. The conference attracted an amount of attention from the daily press of New England seldom accorded to agricultural meetings, and in many journals the sessions were reported in considerable detail. At the close of the meetings the *Springfield Republican* commented editorially as follows:

"To estimate the actual and potential benefits of the conference is impossible, for its coherent variety might appeal to a breadth of interests which can not be mapped or platted and the wholesome strength of the influences may give them life extending beyond our perspective and branching out where we do not see. The idea of a conference on rural progress was a happy conception which was well carried out. It furnished an excellent precedent well worth following."

The need of a conference of this sort may be attributed in part to an increasing realization of the complexity of the problems confronting rural progress and the desirability of thorough understanding and sympathetic cooperation on the part of the various agencies engaged in their solution, and in part to a broader conception of the responsibility of the agricultural colleges and experiment stations in all that pertains to rural welfare. It indicates a belief that these institutions are to be looked to not only for advice in the growing of crops and the raising of stock, but also for leadership in matters connected with the farmer's roads, his school, and his home—in short, that they are potential agencies of education to an extent as yet realized only in part by the community and perhaps not fully by the institutions themselves.

Something as to the part which the experiment stations may take in such advancement was developed in the address of Doctor True on The Broad Outlook of the Agricultural Experiment Stations, which he declared to be along educational lines and for the benefit of the village and urban residents as well as the farmers.

"With their existing financial limitations the stations have properly given their attention thus far principally to the needs of our large agricultural industries, but they have also done much which is of use to village and city people, and they will undoubtedly enlarge their work in this direction as time goes on and funds increase. The farmers need have no fear that the stations will forget them or neglect their interests, but should rather rejoice that in the stations they have a powerful agency for bringing city people into closer sympathy with rural people."

"Already," he went on to say, "the work of the stations has created an entirely new agricultural literature, and . . . laid the foundations for a sound agricultural pedagogy, and . . . they must ever supply the new materials by which the courses can be strengthened and improved. But their work has a far more fundamental and far-reaching purpose; namely, to make agriculture a progressive industry and the masses of agricultural workers progressive men. Many plans for rural improvement have been made by philanthropists and statesmen, but they have largely been failures because they were imposed on the unwilling minds and hearts of unprogressive people. But if the rural people themselves awake and make their plans of improvement we may surely expect wonderful things. As an arouser of desire for improvement and a stimulator to intelligent effort to make the country a better place to live and work in, the agricultural experiment station has its chief importance and its highest mission. And it is for this service that the stations especially commend themselves to all the friends of rural progress, for if these fountains of new knowledge are kept strong and pure their waters will spring up forever to replenish the life of countless generations of rural people."

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Nitron as a microchemical reagent, H. L. Visser (*Chem. Weekblad, 3 (1906), pp. 743–746; abs. in Chem. Zentbl., 1907, I, No. 4, p. 302; Jour. Soc. Chem. Indus., 26 (1907), No. 4, pp. 167, 168; Jour. Chem. Soc. [London], 92 (1907), No. 535, II, p. 394*).—The author recommends that instead of weighing the nitron nitrate in determining nitric acid the determination be made by comparing the depth of the layer of precipitate with that of a corresponding precipitate from a solution of known content of nitric acid in glass tubes of equal diameter.

It is stated that nitron also forms almost insoluble salts with nitrous, chloric, perchloric, oxalic, and salicylic acids, which may be distinguished under the microscope by differences of crystalline form. "Nitron may also be used for the microchemical detection of saccharin if the latter be first converted into *o*-sulphaminobenzoic acid by the action of dilute alkali." The characteristic crystalline form of this substance is easily detected with the microscope.

Note on the determination of nitrogen by the Jodlbaur method, H. Volkholz (*Chem. Ztg., 30 (1906), p. 370; abs. in Ztschr. Angew. Chem., 20 (1907), No. 23, pp. 960, 961*).—The author simplifies and shortens this method by adding the zinc dust in small portions and with vigorous shaking to the hot acid solution.

Determination of nitrous acid and its separation from nitric acid, G. Maderna and G. Coffetti (*Abs. in Chem. Ztg., 31 (1907), No. 29, p. 375; Analyst, 32 (1907), No. 375, p. 234*).—The method proposed is based upon the fact that in the presence of acetic acid, or, preferably, citric acid, nitrous acid is reduced to nitric oxid by ferrocyanids, and the liberated gas may be collected and measured. Under these conditions nitric acid does not react with ferrocyanid.

Detection of nitric and nitrous acids, H. W. Wagner (*Pharm. Centralhalle, 48 (1907), pp. 5–7; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 533, II, p. 196*).—A slight modification of Sprengler's phenol test is recommended.

On the method of separating potassium from sodium as chloroplatinates, J. Morozewicz (*Bul. Acad. Sci. Cracovie, 1906, pp. 796–803; abs. in Chem. Abs., 1 (1907), No. 8, p. 972*).—Eighty per cent alcohol is considered preferable to absolute alcohol for washing out the sodium chloroplatinate. The polarizing microscope will detect doubly refracting salts in a drop of the slowly evaporated aqueous solution of the potassium chloroplatinate and thus determine its purity.

The estimation of free acids in superphosphates, J. Van Dormael (*Bul. Soc. Chim. Belg., 21 (1907), No. 3, pp. 103–115; abs. in Jour. Soc. Chem. Indus., 26 (1907), No. 8, p. 424; Analyst, 32 (1907), No. 374, p. 182*).—The method proposed embodies those of Herzfelder and Thomson and is based upon double titration with fourth-normal sodium hydroxid solution of the ether or alcohol extract (evaporated to dryness and taken up in water) of the dried superphosphates, titrating first with methyl orange and then with phenolphthalein. It is stated that as a rule the amount of free sulphuric acid in superphosphates is negligible, and therefore the whole of the sodium hydroxid consumed may be regarded as neutralizing only free phosphoric acid.

A short scheme of water analysis, J. A. HUGHES (*Merck's Rpt., 16 (1907), No. 5, pp. 128, 129*).—A simple scheme, which is considered sufficient to enable one to quickly form a very good opinion of the potability of a given water, is described.

Chemical soil analysis for investigations in plant physiology, E. A. MITSCHERLICH (*Landw. Jahrb., 36 (1907), No. 2, pp. 309–369, pl. 1, figs. 10*).—The method proposed by the author (see also E. S. R., 18, p. 417), is based upon the assumption that solubility in water saturated with carbon dioxid is a measure of the plant food in the soil at the disposal of cultivated plants. Studies of the influence of the elements of time, carbon dioxid content of the solvent, amount of solvent, and temperature are reported and the details of the method recommended are given.

The extract is prepared by digestion of the soil with 10 or 25 times its amount of solvent for 1½ hours at 30° C. in a flask provided with a constant stirring apparatus and connected with a cylinder of compressed carbon dioxid which keeps the solution in the flask saturated with carbon dioxid. The extract is clarified by suction through a clay filter and aliquot portions are taken for determination of nitrogen by the phenol-sulphuric acid method, potash by the ordinary procedure, final weighing being made of reduced platinum according to Regel (E. S. R., 18, p. 108), phosphoric acid by the Wagner-Stutzer molybdic method, and lime by precipitation with ammonium oxalate as usual.

The errors inherent in the various determinations are discussed and a series of tests are reported which show that the method is capable of detecting small variations in the composition of soils due to applications of fertilizers.

On the question of the method of determining nitric acid in soils (*Vyestnik Sakh. Prom., 1906, No. 44, p. 652; abs. in Centbl. Zuckerindus., 15 (1907), No. 34, pp. 923, 924*).—This is a brief note on work of Welbel, Frankfurt, and Duschetschkin on this subject, which led to the conclusion that the methods of determining nitric acid in soils in which the soil is digested with water for 48 hours give too low results, due to reduction of nitrates. Two hours' digestion is fully sufficient to extract the nitric acid of soils. If longer treatment is necessary, accurate results can be obtained by adding chloroform, thymol, or other substances which check the activity of the lower organisms that reduce nitrates.

Notes on the determination of nitric acid in chernozem soils, V. I. SAZANOV (*Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 7 (1906), No. 4, pp. 381–387*).—The experiments of the author show that for the estimation of the nitrates it is necessary not to allow the soil to remain in contact with the water, in the extraction, any longer than is required for the settling of the greater part of the fine particles. Longer contact causes a rapid diminution of the nitrates. Chloroform prevents this decrease of the nitrates. In keeping soils, the amount of nitrates increases with the time if the soils are preserved in the humid state. Chloroform does not prevent this increase. A quick drying (in the sun) prevents change in the nitrate content.—P. FIREMAN.

A new calcimeter, T. BIÉLER-CHATELAN (*Chron. Agr. Vaud, 20 (1907), No. 6, pp. 114–120, fig. 1*).—A simple apparatus for the rapid determination of calcium carbonate in soils is described and its practical use explained.

The use of biological methods in the analysis of food stuffs, A. J. J. VANDEVELDE (*Biochem. Ztschr., 1 (1906), No. 1–2, pp. 1–7*).—From his investigations with plasmolyse and hemolyse, the author concludes that it is possible to judge of the properties of different substances by biological methods and has reported determinations of the coefficient of toxicity of alcohols, aldehydes, acids, essences, oils, and similar substances of interest from their relation to food materials.

Concerning methods for the analysis of flours, breads, bakers' goods, alimentary pastes and similar goods, spices, and condiments (*Bul. Mens. Off. Renseig. Agr.* [*Paris*], *6* (*1907*), *No. 4*, *pp. 405–416*).—The directions for analysis are in accordance with the French law of August 1, 1905.

Comparative methods of determining the dry matter in potatoes, A. J. Hansen (*Tidsskr. Landbr. Planteavl, 13* (*1906*), *pp. 316–338*).—The results of the investigation show that the dry matter in potatoes may be determined with as much accuracy by drying as in other root crops, and that a good sample is best obtained by dividing each tuber into 8 parts by 3 perpendicular cuts through its center and selecting one or more of these parts for comminution. The author finds that results obtained by calculation of dry substance from determinations of specific gravity according to Maercker's tables are 1 to 2 per cent too low.—F. W. WOLL.

The mono-amino acids of "syntonins" from beef, E. Abderhalden and T. Sasaki (*Ztschr. Physiol. Chem., 51* (*1907*), *No. 4–5, pp. 404–408*).—Glycocoll, alanin, valin, leucin, prolin, asparagin, glutamin, phenylalanin, and tyrosin were obtained from syntonin in addition to humin. The results are expressed quantitatively.

A rapid method for the determination of fat in grits, meal, rice, and cerealine, O. Schütte (*Pure Products, 3* (*1907*), *No. 6, pp. 287–291*).—The method outlined consists in shaking a sample vigorously for 15 minutes in petroleum ether, filtering after settling and determining the amount of fat in an aliquot portion by evaporation and drying to a constant weight. As shown by comparison the results are, in the author's opinion, satisfactory, though on an average of 23 analyses they were 0.03 per cent lower than those obtained by the Soxhlet method.

A method is also described for the use of raw cereal in which the finely ground substance is allowed to stand over night in petroleum ether, filtered, and the fat determined in an aliquot portion. As shown by 8 comparative tests, the results were on an average 0.02 per cent lower than by the Soxhlet method.

The estimation of the unsaponifiable constituents of fat, G. Meyer (*Chem. Ztg., 31* (*1907*), *No. 33*, *p. 423*).—A comparative study of methods.

Concerning nitrogen-free extract in oil cakes, P. Christensen (*Jour. Landw., 55* (*1907*), *No. 1–2, pp. 47–67*).—The experimental study of the composition of oil cake of different sorts led the author to conclude that the determination, in addition to protein and fat, of total carbohydrates, starch, etc., which have food value, is a much more satisfactory procedure for judging the value of these feeding stuffs than the usual proximate analysis which includes crude fiber and nitrogen-free extract by difference. The method of estimating the total carbohydrates which he outlines depends upon the inversion of starch by diastase and acid. Before inversion the material is heated with water in a closed flask for 20 hours at 100° C.

The sugar content of dried chips and sugar-beet chips, F. Strohmer and O. Fallada (*Mitt. Chem. Tech. Vers. Stat. Cent. Ver. Rübenz. Indus. Österr.-Ungar., No. 185, pp. 18–21; sep. from Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 36* (*1907*), *No. 2*).—The study of methods, which the authors report, led to the deduction that digesting the sugar-beet chips in the usual way with hot water may give too high values for the sugar content.

A new decomposition product of gliadin, T. B. OSBORNE and S. H. CLAPP (*Amer. Jour. Physiol., 18 (1907), No. 2, pp. 123–128, figs. 2*).—From gliadin hydrolyzed by boiling for a considerable time with 25 per cent sulphuric acid, a crystalline substance of definite character was isolated, which on vigorous hydrolysis gave prolin and phenylalanin. It seems probable that this substance is a dipeptid. The yield was in the proportion of about 4 gm. from 1 kg. of gliadin.

The quantitative estimation of extractive and protein phosphorus, W. KOCH (*Jour. Biol. Chem., 3 (1907), No. 2, pp. 159–164*).—The method outlined is especially applicable to a study of brain tissue and similar materials and, according to the author, can be generally used in the study of normal and pathological material.

Determination of dry matter in milk, G. HINARD (*Bul. Soc. Chim. France, 4. ser., 1–2 (1907), No. 10, pp. 558, 559*).—In determining total solids in milk the author has endeavored to avoid by the use of formaldehyde the progressive changes which take place in the proteids during prolonged heating. The method as tried experimentally consisted in adding 3 drops of formalin to 10 cc. of milk, coagulating the milk by means of 5 or 6 drops of a 15 per cent solution of acetic acid, and evaporating at 95 to 100° C. Heating for 5 days made a difference of only 0.12 per cent in the weight of the dry matter.

A reaction of formaldehyde with naphthalene in the presence of sulphuric acid, H. DITZ (*Chem. Ztg., 31 (1907), No. 35, pp. 445–447*).—In the presence of naphthalene dissolved in sulphuric acid, formaldehyde in very small quantities is said to give a brown coloration and in large quantities a bright blue coloration. In applying this test to milk the casein is precipitated by dilute sulphuric acid and the naphthalene sulphuric acid reagent is added to a small quantity of the clear whey.

On the determination of water in butter, H. FABER (*Mælkeritid, 20 (1907), No. 11, pp. 199–211*).—Descriptions are given of the following methods of determining the water content of butter in creameries: Gravimetric chemical analysis, the Gray, the Gerber, and the Carroll method. The last method given, which was invented by Professor Carroll in Dublin, in the author's opinion, bids fair to prove the most satisfactory as a preliminary approximate test.—F. W. WOLL.

Note on the determination of volatile fatty acids in butters (Reichert number), L. DE KONINGH (*Chem. News, 95 (1907), No. 2477, p. 229*).—A modification of the Reichert method is suggested for use when the quantity of butter is small and an early analysis is required. The process is as follows:

"The butter is melted in a test tube placed in hot water, and 2.5 gm. of the clear fat are saponified with 12.5 cc. of normal alcoholic caustic potash in a flask fitted with a long vertical tube. When saponified 25 cc. of distilled water are added, and the whole evaporated in a basin to pasty consistency. The soap is dissolved in warm water, made up to exactly 60 cc., and placed in the distilling flask. Fifteen cc. of normal sulphuric acid are then added, also some fragments of clay pipe. The whole is then submitted to distillation and 50 cc. are collected. The distillate is filtered into a 300 cc. flat-bottomed Jena flask and titrated with N/10 sodium hydroxid, with phenolphthalein as indicator. The result may, however, be too high, as during the evaporation of the soap a not inconsiderable quantity of carbon dioxid may have been absorbed, and the N/10 soda used in the titration, unless freshly made, may have become somewhat carbonated. Therefore 0.5 cc. of N/10 hydrochloric acid is added and the carbon dioxid expelled by rapidly heating the liquid to boiling and then boiling gently for 3 minutes. The flask is now rapidly cooled and the titration continued; the liquid should, of course, be colorless. From the total number of cubic centimeters of N/10 soda used 0.5 cc. is then deducted."

The iodin number of olive oil and variations in this value in Tunitian oils, R. Marcille (*Ann. Chim. Analyt., 12 (1907), No. 5, pp. 188–191*).—According to the author's investigations, wide variations occur in the iodin number of Tunitian olive oils.

Glycerin in wine, D. A. Lojodice (*Rev. Vit., 28 (1907), No. 713, pp. 179–185*).—The author finds that the difference between the extract determined by evaporation in a water bath at 100° C. and by drying in a vacuum represents approximately the glycerin content of wine determined by direct methods.

Agricultural laws, E. F. Ladd (*North Dakota Sta. Spec. Bul. 5, pp. 12*).—This contains the text of the State laws relating to the sale of commercial feeding stuffs and stock foods, formaldehyde, Paris green, and commercial fertilizers.

Food and drug laws, E. F. Ladd (*North Dakota Sta. Spec. Bul. 6, pp. 20*).—This contains the State pure-food law and the pure-drug law as amended and reenacted, the paint law, abstracts from other State laws dealing with the adulteration of foods, dairy products, oils and paints, and rulings, interpretations, and suggestions for the guidance of interested parties.

A milk colorimeter, A. Bernstein (*Chem. Ztg., 31 (1907), No. 58, p. 727, fig. 1*).—The apparatus described is intended for determining approximately the fat content of skim milk. The sample to be tested is coagulated with acetic acid and the color or cloudiness of the fluid portion is compared with that of a standard solution which corresponds in appearance to whey having a fat content of 0.15 per cent. The apparatus consists of 2 glass tubes with a blue glass rod in the center of each and a white porcelain background.

Apparatus for the determination of water and fat in butter, F. T. Shutt (*Canada Dept. Agr., Branch Dairy and Cold Storage Comr. Bul. 14, pp. 8, figs. 2*).—This bulletin gives the results of tests of 2 pieces of apparatus now on the market, one designed for determining the amount of fat in butter and the other the water content. Fairly accurate fat determinations were made, but the results with the hygrometer were rather unsatisfactory.

METEOROLOGY—WATER.

The importance of meteorological and weather forecasting for practical farmers, F. Krüger (*Fuhling's Landw. Ztg., 56 (1907), No. 11, pp. 369–386, figs. 3*).—This is a discussion of this subject with a view to facilitating the use of the reports of the German weather service by practical farmers.

Meteorology in the service of agriculture, J. Hudig (*Cultura, 19 (1907), No. 223, pp. 182–189*).

Variations of the meteorological elements of the soil, A. Baldit (*Rev. Auvergne, 23 (1906), No. 4, pp. 269–271*).—Observations with a thermometer, barometer, and hygrometer buried in the soil at a depth of 1.8 m. from June 23–30 are reported. The temperature registered by the buried thermometer was 5° to 6° lower than that of the air thermometer. The barometric pressure in the soil was about 3 mm. higher than that of the barometer in air. The humidity was much higher in the soil than in the air (35 m. above ground). The most important fact observed was that the atmospheric pressure was transmitted to the buried barometer without appreciable lag or diminution of amplitude.

Results of meteorological observations in Brunswick, 1878–1905, Döbr (*Beitr. Statis. Braunschweig, 1907, No. 20, pp. 1–38, map 1*).—Detailed summaries are given.

Meteorological observations by the Biological Agricultural Institute of Amani, German East Africa, V. Lommel (*Pflanzer, 3 (1907), No. 5–6, pp.*

77–82).—Monthly summaries of observations on temperature, precipitation, and humidity at this place during 1906 are given.

Meteorological observations in German East Africa, P. Heidke (*Mitt. Forsch. Reis. u. Gelehrten Deut. Schutzgeb., 19 (1906), No. 1, pp. 40–106*).—Observations at 22 stations during 1899–1902 are summarized.

Rainfall observations in German East Africa, C. Uhlig (*Mitt. Forsch. Reis. u. Gelehrten Deut. Schutzgeb., 18 (1905), p. 352; 19 (1906), Nos. 2, pp. 164–180; 3, pp. 274–290; 4, pp. 305–335*).—Observations at some 70 places during 6 years are summarized.

The Innsbruck good weather wind, A. Defant (*Separate from Ber. Naturw. Med. Ver. Innsbruck, 30 (1905–6), pp. 16, fig. 1*).

Official experiments on hail protection in Italy, Vidal (*Bul. Soc. Nat. Agr. France, 67 (1907), No. 5, pp. 386–400, figs. 2*).—The author takes exceptions to the conclusion from the official tests at Castel-Franco, near Venice, that cannonading is useless as a means of dissipating hailstorms and states that the results obtained in France lead to the opposite conclusion.

A rain gage for agricultural purposes, Grohmann (*Illus. Landw. Ztg., 27 (1907), No. 49, p. 441, fig. 1*).—Simple and convenient forms of a rain gage with measuring apparatus are described.

The psycho-physical aspect of climate, with a theory concerning intensities of sensation, W. F. Tyler (*Jour. Trop. Med. and Hyg., 10 (1907), No. 8, pp. 130–149, figs. 26; rev. in Sci. Amer. Sup., 64 (1907), No. 1645, p. 19*).—The author describes a scheme for the utilization of certain psychical phenomena (personal sensations) as a means of synthesizing meteorological measurements recorded by physical apparatus and proposes certain sensation scales "for correlating these personal sensations with the instrumental meteorological measurements corresponding to them."

Denudation and rainfall, C. Kassner (*Mitt. Justus Perthes' Geogr. Anst., 53 (1907), No. 2, pp. 46, 47; abs. in Science, n. ser., 25 (1907), No. 649, pp. 909, 910*).—It is suggested that in regions of subdued mountain forms there is now probably less rainfall than before leveling, due to erosion, took place, and that the former rainfall distribution can be estimated upon the basis of the approximate land elevation before denudation took place.

A reviewer, M. S. W. Jefferson, of Kassner's article, however, suggests that in many cases denudation has been accompanied by a compensating regional uplift, so that there has probably been in such cases little change in rainfall.

The rainfall in the department of Puy-de-Dôme, J. R. Plumandon (*Rev. Auvergne, 23 (1906), No. 4, pp. 247–264, charts 2*).—The distribution of the rainfall of this region with reference to topography, elevation, etc., is discussed in some detail. It is shown that there is no invariable relation between rainfall and elevation, but in accounting for distribution of rainfall it is necessary to take account not only of the absolute and relative elevation of the region under consideration, but also of the topography of the surrounding country, the form of the average isobars, and the direction of the winds.

Change in the climate of Kansas, F. H. Snow (*Trans. Kans. Acad. Sci., 20 (1906), pt. 2, pp. 288–291; Quart. Rpt. Kansas Bd. Agr., 26 (1907), No. 101, pp. 438–440*).—Replying to a recent article by the Chief of the Weather Bureau of this Department (E. S. R., 18, p. 1109), the author quotes his own records at the University of Kansas, Lawrence, Kans., covering a period of 39 years (1868–1906), to show that there has been an increase of rainfall and humidity and a decrease in velocity of the wind.

The author concludes that his observations "indicate a gradual change in the climate at Lawrence, Kans. And as this locality presents a typical illustration of the climate conditions of eastern Kansas, it is safe to infer that the same changes are taking place over the entire region of which it forms a part. The rainfall and atmospheric humidity have increased and the wind velocity has decreased. The change in the rainfall and wind velocity has been in each case more than 10 per cent, while the increase in the atmospheric humidity has been more than 6 per cent."

The climatology of Kansas, T. B. JENNINGS (*Trans. Kans. Acad. Sci., 20 (1906), pt. 2, pp. 273–276*).—A brief review is given of the available historical records of floods and droughts.

Climate of different parts of the world, M. BUIJSMAN (*Cultura, 19 (1907), No. 224, pp. 277–279*).—This is a contribution to the climate of Cochin-China as indicated by the growth of different species of plants.

The productive capacity of plants and the climatic conditions in Java and Middle Europe, W. DETMER (*Botanische und landwirtschaftliche Studien auf Java. Jena: Gustav Fischer, 1907, pp. 19–26*).—In cooperative tests with maize grown from Java seed, the production of dry matter in the above-ground parts was 4 to 5 times as great in the moist, warm climate of Buitenzorg, Java, as in the cooler, drier, but less uniform, summer climate of Jena.

Influence of spring precipitation on the yield of oats and potatoes and on the starch content of potatoes, A. ALEXANDROV (*Zeml. Ghaz., 1905, No. 41, pp. 579–581; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 7 (1906), No. 4, p. 515*).—On the basis of experiments at the Viatka Experiment Station the author concludes that for oats May rains are more important than June rains, the optimum precipitation during the vegetation period being about 68 mm.; for potatoes, the greater the precipitation in May and June the less the yield and the starch content, and conversely.—P. FIREMAN.

The relation of a diffusion of heat rays to the season of the year, A. DEFANT (*Separate from Ber. Naturw. Med. Ver. Innsbruck, 30 (1905–6), pp. 17*).

Ground water in Hamburg, A. VOLLER (*Jahrb. Hamburg, Wiss. Anst., 23 (1905), Beiheft 1, pp. 7, charts 4*).—The results of observations during 1905 on ground water as related to temperature and humidity of the air, precipitation, and river levels at Hamburg are reported in detail.

Geology and underground water resources of northern Louisiana, with notes on adjoining districts, A. C. VEATCH (*Geol. Survey La. Bul. 4, pp. 209, pls. 25, figs. 18*).—This paper is made up of excerpts from Professional Paper No. 46 of the U. S. Geological Survey (E. S. R., 18, p. 817).

Underground waters of Missouri, their geology and utilization, E. M. SHEPARD (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 195, pp. X+224, pls. 6, figs. 6*).—This report describes the topography and geology of the State and their relations to artesian waters, discussing in detail the underground supplies of each county. The results of investigations of the sources and qualities of waters used for municipal supplies are also reported.

Ground and deep waters of North Carolina, G. MCCARTHY (*Bul. N. C. Bd. Health, 22 (1907), No. 1, pp. 1–14, figs. 6*).—The arrangement of strata in the Atlantic Coast region, particularly in North Carolina, with reference to underground water supplies is discussed, and examinations of several samples of North Carolina deep water are reported.

Water supply of Nome region, Seward Peninsula, Alaska, 1906, J. C. HOYT and F. F. HENSHAW (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 196, pp. 52, pls. 6, fig. 1*).—This paper gives the results of investigations made during the season of 1906 to determine the water supply available for the economical development of the placer mines and water power of Alaska.

The quality of surface waters in Minnesota, R. B. DOLE and F. F. WESBROOK (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 193, pp. 171, pls.*

7, figs. 4).—This paper "outlines the general characteristics of surface waters in Minnesota and the various factors that tend to modify the quality of the drainage. It includes the results of nearly two years' field and laboratory work done by the United States Geological Survey in cooperation with the Minnesota State board of health. First the general features, both natural and economic, that influence the quality of the meteoric water and impart to the lakes and streams their essential characteristics are reviewed. Next each drainage area is considered in detail, the streams are described, the sources of pollution are discussed, and the results of chemical analyses and bacteriological examinations are given. Statistics are presented regarding practically all of the municipal water supplies in the State and the relative value of the surface and ground waters for general consumption is discussed. At the end is a description of the laboratory methods employed in the chemical and bacteriological work."

Pollution of Illinois and Mississippi rivers by Chicago sewage, M. O. LEIGHTON (*U. S. Geol. Survey. Water-Supply and Irrig. Paper 194, pp. 369, pls. 2, figs. 5*).—This is a digest of the testimony taken in the case of the State of Missouri *v.* the State of Illinois and the sanitary district of Chicago, together with the full text of the decision of the Supreme Court on this subject.

The problem of potable water, E. A. MARTEL (*Presse Méd.* [*Paris*], *1907, No. 28, pp. 217–220, figs. 4*).—This article discusses the sources of water supply for Paris, subterranean waters in limestone or chalk, wells and water levels, effect of droughts and deforesting, microbiology of the waters, temperature, protection against pollution, purification, and sterilization.

Water supply and sewage disposal in France (*Rec. Hyg. Pub., 35 (1905), pp. 386–466, 635–731*).—The character of the water supply and methods of sewage disposal in various towns in France are described in a series of reports to the consulting commission of public hygiene of France, with detailed tabular statements of chemical and bacteriological examinations, the interpretation of the results of analyses of water, and tests of methods of purification.

Sewage irrigation at Paris (*Rev. Sci.* [*Paris*], *5. ser., 7 (1907), No. 21, p. 666*).—This is a note on a recent report to the French Minister of Agriculture on work in the Commune of Achères. The amount of sewage is increasing beyond the capacity of the area to dispose of it, and a large extension of the area or the introduction of other methods of purification are considered imperative.

SOILS—FERTILIZERS.

The influence of soil on vegetation, H. FRICKHINGER (*Ber. Naturw. Ver. Schwaben u. Neuburg, 37 (1904–5), pp. 247–277*).—Previous observations on the relation between the character of soils and the vegetation growing on them are briefly reviewed, the importance of mineral matter for plants, with a compilation of analyses of typical rocks and minerals from which soils are derived, is discussed, and experiments with 17 so-called silica-loving and lime-loving plants are reported. The soils used were: (1) That in which the plants were found growing naturally; (2) coarse-grained weathered dolomite; (3) a mixture of quartz and weathered gneiss, and (4) a mixture of humus, calcareous loam, and quartz. The plants experimented with were: *Spergula arvensis, Lycopsis arvensis, Veronica verna, Scleranthus annuus, S. perennis, Sarothamnus vulgaris, Sagina procumbens, Gypsophila muralis, Farsetia incana, Digitalis purpurea, Helichrysum arenarium, Arabis hirsuta, Laserpitium latiforium, L. siler, Coronilla montana, Erysimum cheiranthoides,* and *Agrostemma githago.*

The results show that a small content of silica and calcium carbonate in the soils did not prevent the plant roots from obtaining the necessary amounts of these materials. The so-called silica-loving plants grew vigorously on weathered dolomite rich in lime, provided the porosity of the material was similar to that of the quartz soils. The so-called lime-loving plants grew badly on a calcareous soil which had been rendered very porous by the addition of quartz. They grew well on a siliceous soil which had been rendered compact by the addition of loam and a little calcareous clay.

It seems clear, therefore, that it is the physical and mechanical properties and not the chemical properties which influence the growth and distribution of plants. The difference in growth on sandy soils and on calcareous and clay soils depends solely upon variations in the mechanical condition of the products resulting from the weathering of various soil-forming rocks.

Some factors influencing soil fertility, O. SCHREINER and H. S. REED (*U. S. Dept. Agr., Bur. Soils Bul. 40, pp. 40, pls. 3*).—This bulletin cites previous experiments by the Bureau of Soils and other investigators which are held to indicate the presence of toxic properties in unproductive soils, manifesting themselves in diminished yields of succeeding crops and in the mutually injurious effects of the roots of trees and other plants, and reports experiments with wheat, oat, corn, and cowpea seedlings to determine the behavior of these plants when grown in fresh non-nutrient agar or in that containing the excreta from previous crops of the same plant or of other plants.

From the facts presented in the bulletin the authors conclude that "it is evident that the production of toxic excretions by the roots of plants is undoubtedly a factor of importance in soil fertility. Many experiments have demonstrated that the accumulation of these toxic excretions may temporarily impair the fertility of certain soils. The foregoing experiments have not only shown that infertility may be due to actual toxic conditions of the soil, but also that the toxic conditions may arise from the growth of vegetation. The data given are just as conclusive in showing that the infertility of the soils was not due to their poverty in plant food constituents. . . .

"In our present state of knowledge it would seem that we must regard the excreta of growing roots as one of the main causes of the low yields obtained in improper crop rotations.

"In some types of soil, influenced perhaps by certain climatic environments, there appear to exist conditions which are unusually favorable to the rapid destruction of toxic excretions. Such soils, when planted year after year to the same crop may not only maintain their original productive powers, but even increase with continued cultivation."

Soil improvement for the worn hill lands of Illinois, C. G. HOPKINS and J. E. READHIMER (*Illinois Sta. Bul. 115, pp. 431-443*).—This bulletin is a report of progress in the land improvement work carried on by the station, chiefly in southern Illinois. A plan of the experiments and earlier results have been previously noted (E. S. R., 17, p. 361).

In summarizing the results with wheat on the Vienna experiment field, taking into account the total yields for the last 3 years, it is shown that untreated land produced 11.8 bu. per acre, while with a leguminous crop the yield increased 11.5 bu., and with lime used in addition to the leguminous crop the increase in yield was 34.3 bu. During this period the use of phosphorus gave a further increase of only 5.6 bu. per acre, and the use of potassium of 10.8 bu. It is pointed out that the direct effect of the lime applied in the form of ground limestone is to increase the growth of the crops for green manuring.

In the corn tests for the last 3 years the untreated land produced 109.2 bu. per acre. The use of a leguminous crop alone increased the yield only 9.8 bu., while with the further addition of lime an increase of 50.7 bu. was secured.

Neither phosphorus nor potassium increased the yield of corn beyond that obtained from the use of a leguminous crop and lime.

In pot culture experiments made with red silt loam of unglaciated hill land there was practically no gain except when nitrogen was supplied either directly in commercial form or indirectly by means of a leguminous crop. The effect of phosphorus and potassium was less where decaying organic matter had been provided in the leguminous crop than where the nitrogen was given in commercial form with but little organic matter. Since 1905 practically no effect has been observed from either phosphorus or potassium when applied in connection with growing leguminous crops for soil improvement. These results bear out conclusively the results obtained in the field tests, that marked improvement can be made on this soil by turning under leguminous crops where lime has been applied.

Another series of pot culture experiments was made with soil from worn gray silt loam hill lands of northwestern Illinois. In these tests the amount of oats secured where nitrogen was applied was about 8 times that where no nitrogen was given Lime alone produced no beneficial results, thus indicating that lime and nitrogen together are necessary on this land.

Notes are given on crop rotations, the use of the crops, and the use of fertilizers in soil improvement A rotation for the worn hill lands of southern Illinois, consisting of corn the first year, cowpeas or soy beans the second, wheat the third, clover and timothy meadow the fourth, and pasture the fifth and sixth years is suggested.

Improvement of upland timber soils of Illinois, C. G. Hopkins and J. E. Readhimer (*Illinois Sta. Circ. 109, pp. 8*).—This circular briefly summarizes the more practical results of field experiments carried on in a representative area of the ordinary gently rolling upland timber soils of northern and central Illinois. The profitable system of improvement for such soils, as indicated by the results of these experiments, "is to grow legumes in the crop rotation and make as much manure as possible to maintain the supply of humus and nitrogen and to purchase somewhat more phosphorus, in the form of pure steamed bone meal or fine-ground raw rock phosphate, than is removed from the soil by cropping, so that the soil will grow richer rather than poorer."

The action of water and aqueous solutions upon soil phosphates, F. K. Cameron and J. M. Bell (*U. S. Dept. Agr., Bur. Soils Bul. 41, pp. 58, figs. 5*).—This bulletin reviews the literature bearing on this subject and reports experiments on the action of water on monocalcium, dicalcium, and tricalcium phosphate: the behavior of the three-component system—lime, phosphoric acid, and water—and the four-component system—lime, phosphoric acid, sulphuric acid, and water; the action of solutions of carbon dioxid, sulphurous acid, citrates, ammonium compounds, calcium salts, potassium chlorid, sodium nitrate and chlorid, and other solvents on the phosphates of calcium; and of the behavior of superphosphates and magnesium, iron, and aluminum phosphates under similar treatment. The following is the authors' summary:

"In this bulletin it has been shown that the soil phosphates are decomposed or hydrolyzed by water, with the formation of other phosphates containing relatively more of the base.

"Neutral salts in solution have a marked effect upon the amount of phosphoric acid and of lime going into solution from a lime phosphate, generally increasing both. Lime salts generally decrease the amount of both in solution, as do alkaline solutions, while acid solutions increase it.

"Neutral salts have, however, little effect upon the solubility of the phosphates of iron or alumina, and it is impossible to predict the direction of the effect. Salts which hydrolyze with the formation of acid or alkaline solutions increase the amount of phosphoric acid yielded to the solution by the phosphates of iron and alumina. The phosphates of the soil, whether solid solutions or definite chemical compounds, are of such a nature as to yield a solution containing very small quantities of phosphoric acid. Inasmuch as all soils contain far more basic matter than is sufficient to combine with the phosphoric acid, the least soluble phosphates are the ones which will be formed and will control the concentration of the soil moisture. This fact, together with the well-known phenomena of absorption, gives a satisfactory explanation of the observation that the concentration of the soil moisture is low and varies but little for different soils and with the total amount of phosphoric acid in the soils. For the same reason, the addition of phosphatic fertilizers can not be expected to influence materially the concentration of phosphoric acid in the soil moisture.

"The action of phosphatic fertilizers is, therefore, on the soil and not primarily on the plant; for the concentration in plant food constituents of the solution on which the plant feeds is not materially altered by the addition of phosphatic fertilizers in the amounts used in ordinary field practice.

"The changes in both solution and solid which take place during the progress of leaching superphosphates have been described."

The action of straw manure on the fertility of soils, L. HILTNER and L. PETERS (*Arb. K. Biol. Anst. Land u. Forstw., 5 (1906), No. 3, pp. 99-125; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 534, II, p. 296*).—Pot experiments with lupines and oats grown on lupine and potato soils and fertilized with lupine straw, alone or with the addition of potassium nitrate, and in all cases with a basal ration of potash and phosphoric acid, are reported.

The growth of the oats was retarded by the application of lupine straw. The lupines were not affected. The second year the growth of oats was greater after lupines than after oats. The after-effect of lupine straw on oats following lupines was very favorable, increasing the yield about 50 per cent, so that the net effect of the lupine straw for the first and second years was good. The addition of nitrate increased the effect of the straw. In case of oats following oats the average gain from the use of lupine straw was only about 19 per cent, making a net loss for the 2 years.

Field experiments with lupines, seradella, robinia, peas, and beans gave similar results. Alfalfa was injured by the application of the straw. The favorable action of the robinia straw, which is very woody, was particularly marked. Straw extract greatly increased the yield of mustard, indicating that it is the insoluble matter of the straw which produces the injurious effects.

Recent progress in investigations on nitrification, P. EHRENBERG (*Mitt. Deut. Landw. Gesell., 22 (1907), No. 13, pp. 134–137*).—This is a brief review of recent investigations by Winogradski, Schloesing, Kellner, Godlewski, Boullanger, and Massol, the author, and others.

On changes of availability of nitrogen in soils, I, O. LOEW and K. ASO (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1907), No. 3, pp. 443–448*).—From a study of the character of the nitrogenous excretions from living and dying yeast cells and from investigations on the effect of sterilizing soil by carbon bisulphid and heat, the authors conclude that "on the death of cells all soluble matters can pass through the cytoplasm to the outside. Peptones and mineral nutrients are excreted largely by dying yeast cells and very probably also by the microbes of the soil. This phenomenon throws some light on the beneficial action on crops of bisulphid of carbon when applied to soils."

The activity of bacteria in soils, V. BROMBERG (*Illus. Landw. Ztg., 27 (1907), pp. 177, 178; abs. in Chem. Abs., 1 (1907), No. 10, p. 1309*).—The dependence of nitrogen-fixing bacteria upon the organic matter of the soil is discussed.

Assuming that 1,000 gm. of organic matter is used by bacteria in fixing 8 gm. nitrogen, it is estimated that on a soil containing 2 per cent humus the organisms would produce 42 lbs. nitrogen per acre per year. Increasing the amount of organic material or source of energy in the soil by the addition of humus-forming substances and by cultivation, or by favoring the growth of algæ, tends to raise the nitrogen-accumulating power of the soil. Fallow favors bacterial action most. Plats inoculated with nitrogen-fixing organisms produced 18 to 56 per cent more dry matter and 23 to 130 per cent more nitrogen than uninoculated plats in the case of soy beans, lupines, and seradella.

Further experiments on nitrogen-fixing bacteria, KEDING (*Wiss. Meeresunters. Abt. Kiel, 9, p. 275; abs. in Centbl. Bakt. [etc.], 2. Abt., 18 (1907), No. 10–12, pp. 351–353*).—The author reviews work of other investigators and reports experiments of his own on the nitrogen-fixing bacteria found in sea water and in soils of various kinds. He confirms the conclusion of Keutner that Azotobacter occurring in sea water is, in all respects, similar to that found in soils. Sodium chlorid was found to favor the growth of this organism.

The organism was found in all soil samples examined except those from moor lands. Its fixing power was not affected either by the air drying of soil in which it occurred during 11 months or by rapid drying over sulphuric acid. The organism was capable of assimilating the nitrogen of the air in pure cultures. This power was not increased by associative action of other bacteria and the nitrogen compounds of the air were also without influence.

The use of nitrobacteria in Mexican agriculture, C. MACIAS (*Bol. Sec. Fomento [Mexico], 6 (1906), Nos. 4, pp. 74–78; 6, pp. 257–263, pls. 3; 7, pp. 267–274; 8, pp. 291–309*).—This is a preliminary report on investigations made under the auspices of a special commission on agricultural parasitology, appointed by the Mexican government to study especially the root tubercle organisms of leguminous plants. The report, however, summarizes information regarding all of the more important organisms which are known to fix and transform nitrogen in the soil, as well as those assimilating nitrogen of the air in symbiosis with leguminous plants.

Information regarding the preparation and use of efficient nitragin cultures is given with considerable fullness, the general conclusion being reached that inoculation with this material is not applicable to all soils, but that the individual soil conditions must be studied and that in any case only the more virulent organisms should be used.

The inoculation question in soil bacteriology, P. EHRENBERG (*Fühling's Landw. Ztg., 56 (1907), No. 9, pp. 301–311*).—The progress of investigation on this subject is briefly reviewed, special attention being given to the relative merits of soil and seed inoculation. The conclusion is reached that notwithstanding some disadvantages in its present stage of development, seed inoculation is a satisfactory, cheap, and convenient method when carried out with proper precautions.

Fertilizers, E. B. FERRIS (*Mississippi Sta. Bul. 99, pp. 16, figs. 3*).—This bulletin summarizes the results of 5 years' experiments with fertilizers, manures, and restorative crops on fruits, vegetables, and staple farm crops at the McNeill substation, which is situated on sandy and sandy loam soil "similar to those which occur throughout the long leaf pine belt, which occupies an area of some 15,000 square miles, or practically one-third of the entire State."

Analyses of samples of soil and subsoil from the experimental field showed the following results:

Analyses of soil and subsoil from McNeill substation, Mississippi.

	Soil.	Subsoil.
	Per cent	*Per cent*
Sand	53.440	48.780
Silt	28.650	28.370
Fine silt	3.860	3.450
Clay	5.400	11.920
Phosphoric acid	.023	.017
Potash	142	210
Lime	.220	.170
Magnesia	.162	.140
Iron oxid and alumina	4.800	7.830

The requirements of Mississippi soil of the type experimented with for phosphoric acid, potash, and nitrogen, and the kinds of fertilizer suited to cotton, corn, winter grains, sweet potatoes, sugar cane, cowpeas, peanuts, vegetables, and fruits are discussed as well as methods of application.

The author's conclusions are as follows:

"It is estimated that the farmers of the fertilizer belt of Mississippi are spending $100,000 annually for the purchase of potash in their fertilizers. So far as results at McNeill go to show, this money is practically wasted, and we would urgently insist that the thinking men of the State, merchants, farmers or manufacturers, who can control the composition of fertilizers, either discontinue the use of potash or convince themselves that it is necessary under their own conditions. The McNeill Station would also insist on the use of less cotton-seed meal applied directly to crops, provided, of course, the farmers themselves would get the nitrogen that the soils need from other sources. Cowpeas will supply this nitrogen and they can be grown every year after corn, oats, and practically all vegetables. By rotating the crops cowpeas may also be made to furnish a large part of the nitrogen to such crops as cotton, strawberries, and sugar cane, occupying the land one year or longer. Spanish peanuts will add much nitrogen to soils, especially if hogs are allowed to graze them off, and there is certainly no surer money-maker on the farm than pork grown and fattened on such crops. The growing and feeding of cattle in our State, except for dairy purposes, has not on the whole been profitable, yet we are convinced by work done here, that by buying and selling judiciously, we may, under average conditions, feed cotton-seed products to cattle and get the manure on the land as a profit. [In parking experiments carried on] since 1903 the average yearly increase in yield of corn and cotton, due alone to the manure from cattle, has been 848 lbs. of seed cotton per acre and 21.4 bu. of corn per acre."

Every farmer his own experimenter, H. B. M. Buchanan and J. J. Willis (*Mark Lane Express, 96 (1907), Nos. 3930, pp. 52, 53; 3931, p. 86; 3932, p. 111; 3933, p. 145; 3934, p. 180; 3935, p. 211; 3936, p. 242; 3937, p. 273; 3938, p. 305; 3939, p. 337; 3940, p. 365; 3941, p. 391; 3942, p. 418; 3943, p. 447; 3944, p. 476; 3945, p. 509; 3946, p. 542; 3947, p. 581; 3948, p. 609; 3949, p. 641*).—This article undertakes to present in clear and simple language some of the more important and practical principles governing the general manuring of farm crops, the results of a few experiments showing how these principles have been applied in a practical and profitable way, and to induce farmers to undertake experiments for themselves in a small way.

On the influence of different methods of applying fertilizers on their efficiency, P. Holdefleiss (*Sächs. Landw. Ztschr., 55 (1907), Nos. 1, pp. 3–5; 2, pp. 32–34*).—A brief general discussion of the subject.

Studies of changes which take place in nitrogen when added to soils in different forms of combination, W. A. WITHERS (*North Carolina Sta. Rpt. 1906, pp. 15–18*).—This is a brief summary account of the work of the year in the chemical department of the North Carolina Station which dealt mainly with the changes which nitrogenous matter undergoes in the soil, and is a continuation of previous work along the same line (E. S. R., 17, p. 344). The nitrogenous compounds experimented with were asparagin, ammonium sulphate, sodium nitrite, and sodium nitrate. When these materials were mixed with sterilized soil and immediately extracted by shaking with water for 4 hours about 88 per cent of asparagin and of ammonium sulphate, 92 per cent of sodium nitrate, and only 59 per cent of sodium nitrite were recovered.

The colorimetric method for the determination of nitrites, proposed by the Bureau of Soils, was used in these investigations. As a means of decolorizing the nitrite solutions lampblack extracted with alcohol or gasoline was found to be satisfactory as was also the treatment with ammonia and alum combined, the alum being used in excess.

In soils with or without addition of the nitrogenous compounds named there was no production and some reduction of nitrates or nitrites during February but a considerable formation in September. At the latter period the soil treated with asparagin produced nitrites but no nitrates and that treated with ammonium sulphate produced nitrates but no nitrites. The conclusion is therefore reached "that the oxidation of organic nitrogen and of ammoniacal nitrogen is accomplished by different organisms."

Other observations are reported which indicate that nitrifying organisms are readily transferred from the soil of one pot to that of another by natural agencies. Apparently the nitrous organism is more resistant than the nitric organism but less resistant than the reducing organism. Other lines of work which are in progress or contemplated are briefly referred to.

The interaction of ammonium salts and the constituents of the soil, A. D. HALL and C. T. GIMINGHAM (*Jour. Chem. Soc. [London], 91–92 (1907), No. 534, pp. 677–687*).—In view of the observation that the application of neutral ammonium salts, such as sulphate and chlorid, has resulted in the production of an acid reaction in soils, the authors undertook the investigations which are here reported to determine the actual effects which are produced when dilute solutions of ammonium salts are brought in contact with the separate approximate constituents of soils, viz, sand, clay, humus, and calcium carbonate. The method of procedure was, in general, to shake 100 gm. of dry material for 24 hours with a solution of 300 cc. of a solution of ammonium salts, then to determine whether there had been any increase in acidity or evolution of ammonia.

The trials with sand gave absolutely negative results and are not reported. In the case of clay there was no change of reaction and no withdrawal of the acid radicle from the solution. The reaction of the ammonium salts on the clay was apparently purely one of double decomposition. Complete absorption of the base did not occur even when as much as 50 gm. of clay to 1.6 gm. of ammonium chlorid was used. Much the same results were obtained with ammonium carbonate and phosphate as with ammonium chlorid.

In the case of the phosphate and carbonate, some of the acid was also removed from solution. It was observed that when ammonium salts were used in excess of the clay, reaction proceeded until a definite point was reached and then stopped, "so that a given weight of clay removes the same amount of ammonium from solution, whatever the strength of the solution of ammonium salt with which it is in contact." It was found that when varying quantities of clay were shaken with fifth normal and tenth normal solutions of ammonium chlorid, 100 gm. of clay withdrew approximately 0.147 gm. of ammonium from solution, whatever the quantity of solution with which it was in contact. This proportion, however, was found to vary with different samples of clay used.

When calcium carbonate was shaken up with solution of ammonium salts the reaction was of the same type as with clay. The addition of 10 gm. of calcium carbonate to 50 gm. of clay increased somewhat the precipitation of ammonium, but did not change the type of the reaction. "Since few soils would contain as much as 10 gm. of calcium carbonate per 50 gm. of clay, it may be concluded that the main reaction when ammonium salts are applied to the soil takes place with the clay, although the calcium carbonate will afterwards continue to decompose the zoolitic ammonium compound as ammonium carbonate is removed by nitrification."

Experiments of similar character with different kinds of peat showed that there was no production of acidity when any of the samples of humus were shaken up with the solutions of ammonium salts. In experiments with peat, which had been extracted with hydrochloric acid and thoroughly washed with hot distilled water, there was apparently a slight production of acid and withdrawal of ammonium from solution. The ammonium had been replaced by calcium, small quantities of which had remained in the peat in spite of the treatment it had received. "It seems, however, certain that free 'humic acid' can to some extent decompose ammonium salts with the formation of an insoluble ammonium compound, and this is confirmed by the observation that whereas the humus, after all mineral acid had been washed away, yielded a brown solution on shaking with pure water, when shaken with the ammonium salt a colorless solution resulted. As free 'humic acid' does not appear to be a normal constituent of soils, this experiment does not vitiate the general conclusion reached by the authors that the constituents of the soil do not react with solutions of ammonium salts to produce a free acid. For the acid observed in the field experiments quoted a biological origin has now been found."

Can calcium carbonate cause loss of ammonia by evaporation from the soil? T. TAKEUCHI (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1907), No. 3, pp. 433–436*).—From a study of the reaction between calcium sulphate and ammonium carbonate and calcium carbonate and ammonium sulphate, the author concludes that "there is no danger of losing any significant amount of ammonia by manuring a soil with ammonium sulphate where calcium carbonate is present."

The cause of the lower efficiency of ammoniacal nitrogen as compared with nitric nitrogen (*Abs. in Saaten, Dünger, u. Futtermarkt, 1907, No. 17, p. 483*).—The conclusion of Wagner that the lower efficiency of ammoniacal nitrogen is due to loss of ammonia in soils containing calcium carbonate is briefly referred to.

On the prospects for natural and artificial nitrogenous compounds in the service of agriculture, K. RÖRDAM (*Tidsskr. Landbr. Planteavl, 12 (1905), pp. 381–410*).—A detailed discussion of the present sources of nitrogenous fertilizers and the prospects for their use for agricultural purposes.—F. W. WOLL.

On the exhaustion of the Chilean nitrate of soda deposits, W. OBST (*Saaten, Dünger, u. Futtermarkt, 1907, No. 11, pp. 313–317*).—The possibility of the exhaustion of the Chilean deposits and of supplying nitrogen compounds by artificial means is discussed.

Nitrate of soda propaganda (*Asoc. Sal. Propaganda, Circ. Trimest. 41, 1907, pp. LXVI+165*).—Detailed statistics of production and consumption of nitrate of soda are given, with reviews of investigations relating to the production of nitrogen compounds from the air and their comparison with nitrate of soda as a fertilizer.

Lime nitrogen as a commercial substitute for nitrate of soda, A. Frank (*Illus. Landw. Ztg., 27 (1907), No. 43, pp. 388–391*).—In this paper, which was read before the International Congress of Agriculture at Vienna, the author discusses the commercial possibilities of lime nitrogen in an optimistic manner.

On lime nitrogen, I, G. Bredig et al. (*Ztschr. Elektrochem., 13 (1907), No. 9, pp. 69–75; abs. in Chem. Abs., 1 (1907), No. 10, p. 1224*).—The authors maintain that neither the theory of a high temperature of reaction nor that of finely divided carbid explains the absorption of nitrogen by calcium carbid in presence of calcium chlorid and other substances. They believe that calcium chlorid acts as a catalyzer.

Experiments were made at 800° and 700°, the calcium carbid being heated electrically in a nitrogen atmosphere. The temperature was read by means of a thermo-couple and kept constant either by shutting off the supply of nitrogen or by diminishing the heating current. At 800° a mixture of calcium carbid with 10 per cent of calcium chlorid absorbed in 2 hours 22 per cent of nitrogen, and calcium carbid alone only 3.1 per cent. Other substances, such as lithium chlorid and sodium chlorid, act also as catalyzers, but to a smaller extent; lime, magnesia, calcium fluorid, and sea sand have little or no action. At 700° the rapidity of the reaction decreases, but much more in case of calcium chlorid than in that of lithium chlorid or sodium chlorid.

On atmospheric nitrogen fertilizers, H. Briem (*Centbl. Zuckerindus., 15 (1907), No. 30, pp. 816–818*).—Progress in the manufacture of lime nitrogen and lime niter and in tests of the fertilizing value of these materials is briefly reviewed with a short bibliography of the more important investigations relating to the subject.

Nitric acid from the air (*Ztschr. Electrochem., 13 (1907), Nos. 9, pp. 75–77, figs. 2; 18, pp. 190–198, figs. 24; 19, pp. 210–221, figs. 28; 20, pp. 225–234, figs. 36; 21, pp. 237–255, figs. 61; 22, pp. 280–286, figs. 11*).—The various technical processes and apparatus which have been devised for the artificial production of nitric acid from the air are quite fully described in this article.

On the electro-synthetic production of certain nitrogenous compounds of agricultural value, Bruttini (*Bol. Quind. Soc. Agr. Ital., 12 (1907), No. 7, pp. 245–248*).—A brief review of recent progress in the manufacture of such products.

Norwegian lime niter, I. Bjerknes (*Tidsskr. Norske Landbr., 13 (1906), No. 9, pp. 385–396*).—The article contains an illustrated description of the Notodden lime-niter factory (Birkeland-Eyde process).—F. W. Wool.

Fertilizer experiments with lime nitrogen and Norwegian lime niter, H. von Feilitzen (*Deut. Landw. Presse, 34 (1907), Nos. 28, pp. 229, 230; 29, p. 243*).—In pot experiments with oats, barley, spring wheat, and potatoes on sand and loam soils lime nitrogen was very nearly equal to ammonium sulphate. With oats, barley, spring wheat, on moor soil of better quality the action of the lime nitrogen was also good, but very poor and much inferior to other fertilizers on oats and potatoes on moor soils which were not well decomposed. The lime niter was fully equal in effect to nitrate of soda in experiments with oats on sand and moor soils. In fact the lime combination with nitrate seemed somewhat better for oats than the sodium compound. The investigations were in continuation of earlier work (E. S. R., 17, p. 17; 18, p. 19).

Further comparative experiments with lime nitrogen and lime niter on barley and oats, R. Otto (*Deut. Landw. Presse, 34 (1907), No. 36, pp. 295, 296*).—In plat experiments on different kinds of soil the results with lime nitrogen were somewhat inferior to those with nitrate of soda.

On bat guano from Marianne Islands, S. Kanamori (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1907), No. 3, pp. 461–464*).—Pot experiments with barley to test the availability of the nitrogen of this guano, a large part of which is in the form of chitin, are reported. The results show that the undecomposed chitin is not a readily available source of nitrogen.

Concentration of sugar beet vinasse for fertilizer, M. P. Kestner (*Betterave, 1906, No. 411, pp. 403–406; abs. in Chem. Abs., 1 (1907), No. 9, pp. 1159, 1160*).—Instead of using the vinasse for recovery of potash as usual, it is proposed to mix the dried vinasse with peat or other absorbent material and thus prepare a fertilizer containing nitrogen as well as potash. The increased cost of preparation is said to be offset by the higher value of the product.

Continued test of nine phosphates with different plants, H. J. Wheeler and G. E. Adams (*Rhode Island Sta. Bul. 118, pp. 55–86*).—A previous bulletin reported the results of these tests up to and including 1901 (E. S. R., 18, p. 619). This bulletin reports a continuation of the tests with soy beans in 1902; with Alaska peas, beans, squashes, potatoes, ruta-bagas, turnips, mangel-wurzels, barley, millet, oats, cabbage, tomatoes, lettuce, spinach, and crimson clover in 1903; and with oats in 1904; also with redtop following the miscellaneous crops grown in 1903.

The experiments embraced tests of the relative efficiency of the same 9 phosphates (dissolved boneblack, dissolved bone, acid phosphate, fine ground bone, basic slag meal, floats, raw and roasted redondite, and double superphosphate) used in previous trials on the same soil, limed and unlimed. The applications of phosphates were equalized for the first time in 1902, sufficient amounts of each phosphate being added in that year to bring the rate of application for the entire period, 1894–1904, up to 67.12 lbs. of phosphoric acid per acre per annum.

As in previous trials liming greatly increased the efficiency of roasted redondite but was without influence on the raw redondite, as "in several cases in the limed series the results were better without than with the raw redondite."

"In the unlimed series neither the raw nor roasted redondite proved to be of much practical value when used in connection with most of the varieties of plants. The crimson clover, potato, and especially the Japanese millet, oat, and golden millet, furnished, however, some notable exceptions.

"Floats gave very good results with the soy bean, peas, crimson clover, mangel-wurzel (on limed land), barley (on limed land), potato (on unlimed land), Japanese millet, oat, and golden millet, but they proved highly inefficient especially for the Hubbard squash, ruta-baga, crook-neck squash, flat turnip, cabbage, mangel-wurzel (on the acid unlimed land), tomato, lettuce, New Zealand spinach, and red valentine bean.

"As a rule in the unlimed series, especially in the case of plants which are subject to injury by acid soils, double superphosphate failed to give good results. The same inferior action, in a less degree, was observed in the case of certain plants both with dissolved boneblack and acid phosphate.

"In one or two cases the results with acid phosphate were quite poor even in the limed series, but whether this was incidental or due to the presence of some compound peculiar to this substance, which is particularly toxic to certain plants, remains to be determined. . . .

"Basic slag meal and fine ground bone proved to be excellent phosphatic manures for acid soil, the former being immediately efficient and the latter becoming so after remaining in the soil for 2 or 3 years or long enough for extended decomposition to result.

"These results ought to show that attention must be paid to the kind of crop, the kind of phosphate, and the kind of soil, if one will make sure that the phosphoric acid shall pay proper returns for the money employed in its purchase."

The influence of contact with the soil on the absorbability of soluble phosphates, C. SCHREIBER (*Rev. Gén. Agron., n. ser., 2 (1907), No. 2, pp. 49–53*).—Pot experiments with superphosphate, Thomas slag, and precipitated phosphate on ferruginous soil are reported which show that prolonged contact with the soil destroys the absorbability of available phosphates. This retrogression varies with the character of the phosphate, being much greater in the case of superphosphates than of Thomas slag and precipitated phosphate.

Wolters phosphate, E. WEIN (*Deut. Landw. Presse, 34 (1907), No. 35, pp. 289, 290*).—Comparative plat tests of Wolters sodium phosphate and potassium phosphate, superphosphate, and Thomas slag on mustard, meadows, potatoes, barley, oats, and clover, show the Wolters phosphate to be readily available and as effective as superphosphate.

Ground limestone for acid soils, C. G. HOPKINS (*Illinois Sta. Circ. 110, pp. 19, figs. 5*).—The character and action of caustic and carbonate lime are briefly explained. The advantages of limestone over caustic lime for use under ordinary conditions in Illinois are pointed out, and the best methods of applying lime on such soils are outlined.

"As a general rule, we should use lime only to correct the acidity of the soil, and this is necessary only where there is difficulty in obtaining a good stand and luxuriant growth of a leguminous crop, such as red clover. As to the form of lime to use for this purpose, the farmer must be governed somewhat by the cost of the material. Fine-ground limestone will be both the best and the most economical form of lime to use wherever it can easily be obtained. If caustic lime be used, we should make special provision to maintain the humus in the soil."

The conclusions drawn are based upon experiments by the Pennsylvania and Maryland stations, as well as on those carried on for a number of years by the Illinois Station. As an average of 50 tests carried on by the latter station "during the last 3 years on the soil experiment fields at Vienna in Johnson County, at Cutler in Perry County, at Dubois in Washington County, at Odin in Marion County, and at Edgewood in Effingham County, the value of the increase produced by lime or ground limestone has been $2.69 an acre a year, counting corn worth 35 cts. a bushel, oats 25 cts., wheat 70 cts., and clover hay worth $6 a ton. As an average of 20 tests on these fields, the yield of corn has been increased 6.6 bu., and as an average of 18 tests the yield of wheat has been increased 4.8 bu. per acre, both of these crops being grown in rotation with legume crops on both the limed and unlimed land. As an average of 7 tests the yield of clover has been increased 0.37 ton of air-dry hay per acre, and liming has increased the yield of oats 10 bu. per acre, but this is an average of only 5 tests."

AGRICULTURAL BOTANY.

Some factors determining the structure of plants, J. LAURENT (*Rev. Gén. Bot., 19 (1907), No. 220, pp. 129–160*).—A study was made of a number of the factors that determine the structure of plants, and as a result of his investigations the author concludes that of the internal factors changes in turgescence through changed osmotic pressure produce the principal variations in growth, and that of a considerable number of specific factors studied those capable of increasing osmotic pressure are capable of influencing the structure of the plant. A bibliography is appended.

Notes on polyembryony, M. T. COOK (*Torreya, 7 (1907), No. 6, pp. 113–117, figs. 3*).—On account of the importance of plant-breeding experiments with tropical fruits, the author describes cases of polyembryony in the mango and the rose apple. The mango, which is recognized as a very important fruit in the Tropics, is being studied with a view to securing improved varieties, but in connection with breeding experiments the possiblity of several embryos must be considered.

The effect of acids, alkalis, and neutral salts on the fermentative activity of yeast cells, E. DRABBLE and DAISY G. SCOTT (*Bio-Chem. Jour., 2 (1907), No. 7–8, pp. 340–349, dgm. 1*).—An account is given of observations on the effect of acids, alkalis, and neutral salts on the rate of fermentation induced by yeast cells and also some notes on the rate of multiplication of yeast cells in culture media to which a neutral salt had been added to increase the osmotic pressure. The solutions employed were sodium chlorid, potassium chlorid, sodium nitrate, potassium nitrate, hydrochloric acid, nitric acid, sodium hydroxid, and potassium hydroxid, all of which were made up in various fractional portions of gram-molecular strength.

The neutral salts failed to exercise any marked inhibiting action on the fermentative activity of yeast when added to sugar solutions in strengths of 0.1, 0.01, 0.001, and 0.0001 gram-molecule. Sodium and potassium hydroxids of 0.1 gram-molecular strength entirely prevented fermentation. The weaker strengths depressed the action, while 0.0001 affected the process but little. Hydrochloric and nitric acids of the weaker strengths depressed the action of yeast and at 0.1 strength entirely prevented fermentation and completely inhibited the reproduction of yeast. The lower concentrations permitted slight reproduction of the cells. In all strengths of the neutral salts employed the cells reproduced actively. The hydroxids were found to be destructive at a concentration of 0.1 gram-molecule and at this strength prevented any reproduction. At the lower concentrations, except 0.01 per cent potassium hydroxid, reproduction took place.

In a series of cultures containing sodium nitrate of strengths differing by one-tenth from 1.0 to 0.1 gram-molecule the greatest reproduction was found in the media containing 0.2 sodium nitrate. From this stage increasing strengths of the salt depressed the activity until no reproduction took place at 0.7 per cent. At greater strengths than this the solutions proved destructive to some of the cells.

Recent investigations on the development of the ascomycetes, P. CLAUSSEN (*Ber. Deut. Bot. Gesell., 24 (1906), Generalversammlungs-Heft, pp. 11–38, figs. 7*).—A review is given of some of the more recent literature relating to the life history of the ascomycetes. A bibliography of about 100 titles is included.

Utilization of nitrogen in air by plants, II, T. JAMIESON (*Agr. Research Assoc. [Scot.] Rpt. 1906, pp. 29–117, pls. 2; abs. in Chem. News, 95 (1907), No. 2474, p. 203*).—Experiments are reported upon that were conducted to prove that plants take up nitrogen from the air by means of special trichomes, called by the author "albumin generators," which were described in a previous communication (E. S. R., 18, p. 125).

Cultures were made in pots as well as water cultures with rape, cress, frogbit, azolla, chickweed, and mimulus, which are reported upon in detail. It appears that gains in nitrogen were made by each of these plants. Expressed in percentages of dry weight the gains were as follows: Rape 3.998, cress 2.693, frogbit 2.105, azolla 1.876, chickweed 0.541, and mimulus 0.392 per cent. The details of the analyses are given in an appendix to the report.

Root action and bacteria, S. PICKERING (*Nature [London], 76 (1907), No. 1962, pp. 126, 127*).—In previous publications (E. S. R., 15, p. 474) it is shown that injurious effects followed the growing of grass over the roots of freshly planted apple trees at the Woburn experimental fruit farm. The conclusion at that time was that the effect was due to a poison produced either directly by the grass or indirectly through the agency of bacteria. Subsequent investigations have strengthened the view that bacteria are probably the principal agents in causing the injury.

In investigating this subject trees were planted in pots, the soil of some of which was sterilized, others partially sterilized, and some untreated. All those which were untreated started growth immediately, while of the 9 in sterilized soil, 2 started about 2 days later than those unsterilized or those in which the soil had been partially sterilized, 6 were retarded for at least 14 days, and 1 did not grow at all. It is believed that sterilization, while not destroying all the bacteria, did have the effect of killing some bacteria which are connected with root activity.

The nature of starch and its reactions depending upon different media, J. Wolff (*Rev. Gén. Sci., 18 (1907), No. 11, pp. 459–464*).—Attention is called to the differences noted between starch as it exists in the leaves and other green organs of plants and that deposited as reserve material in various parts of the plant.

The effect of malt diastase on starches of different origin and at different temperatures is described. The proportion of starch transformed in experiments with malt diastase was found to vary with the temperature. Only 5 per cent of potato starch was transformed at 55° C., while 90.3 per cent was transformed at 65°, the temperature at which this starch becomes gelatinized. The average of a number of samples of rice showed 9.7 per cent transformed at 55° and 31.1 per cent at 65°, the gelatinization of this starch taking place at 80°. Of barley starch 53.3 per cent was transformed at 55° and 96.2 per cent at 65°. Wheat starch was transformed to the extent of 62.2 per cent at 55° and 94.6 per cent at 65°. No cornstarch was transformed by the malt diastase at a temperature of 55°, 18.5 per cent was transformed at 60°, and 54.6 per cent at 65°. Other starches showed a wide variation, and considerable differences are noted for starches from different varieties of the same plant.

The changes of starch during germination and the action of diastases under the influence of various chemical and physical agents are discussed at some length.

On the occurrence of sucrase and saccharose in different parts of the grape, V. Martinand (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 24, pp. 1376–1379*).—In a previous publication (E. S. R., 13, p. 225) the author called attention to the occurrence of invertin or sucrase in grapes, grape must, and wine, remarking that the enzym occurred in considerable quantity, sufficient to ferment all the sugar contained in the fruit.

In the present paper the author gives an account of investigations to determine the distribution of sucrase, and he finds that it occurs in practically every part of the grapevine. Saccharose was observed in the leaves, in the pulp of the grape, and in small quantities in the roots, but he was not able to recognize it in the juice obtained from the grapes without pressure, nor in the woody part of the vine.

From his investigations the author concludes that the hydrolysis of saccharose may take place in any of the parts of the grape through the intervention of sucrase occurring naturally in it, and that there is always a considerable excess of the enzym which is capable of fermenting the must obtained under pressure as well as the saccharose which may be added. Without this ferment it would be necessary to resort to the use of yeast or other hydrolyzing agents in the fermentation of the grape juice.

On the relation between the magnesium oxid and calcium oxid in the leaves of various plants during different periods of growth, J. Seissl (*Ztschr. Landw. Versuchsw. Oesterr., 10 (1907), No. 3, pp. 88–101*).—The author investigated the ratio between the calcium and magnesium oxid content of a considerable number of plants at various periods of their development.

About 20 species of vascular plants were subjected to analysis and the results obtained are given in tabular form. The experiments covered portions of 3 seasons, and slight fluctuations were noted between the ratio of these 2 substances in the ash analyzed in different years. In nearly every instance there was a progressive increase in the ratio of the lime to the magnesia content toward autumn. In only 2 samples of vascular plants was the lime content greater than that of the magnesia. Similar ratios were obtained for a number of seaweeds, but in an analysis of a number of fungi, mostly basidiomycetes, the lime content was only about one-third that of the magnesia.

Phaseolunatin and the associated enzyms in flax, cassava, and Lima beans, W. R. DUNSTAN, T. A. HENRY, and S. J. M. AULD (*Proc. Roy. Soc. [London], Ser. B, 79 (1907), No. B532, pp. 315–322*).—It having been stated that several cyanogenetic glucosids may exist in the Java beans instead of one, as reported in the previous paper (E. S. R., 18, p. 330), the authors have reviewed their previous investigations and claim that in the Java beans there is no cyanogenetic glucosid except phaseolunatin. This glucosid is said to be identical with linamarin in flax and the enzyms of the Lima beans, flax, and cassava decompose it.

A study was made of the enzyms present in Lima beans, and there seems to be evidence to establish the identity of the α-enzym with yeast maltase. Since, however, the enzym preparation obtained from Lima beans decomposes amygdalin and salicin, it is believed to also contain a β-enzym identical with or similar to emulsin. A mixture of the 2 enzyms is believed to occur in cassava and flax, as enzym preparations from these sources behave in identically the same manner as preparations obtained from Lima beans. It is further stated that yeast is capable of decomposing phaseolunatin, amygdalin, and salicin, and on this account it is assumed to contain an emulsin-like enzym as well as maltase.

Investigations on the separation of vicianin and its diastase from the seeds of various leguminous plants, G. BERTRAND and L. RIVKIND (*Bul. Soc. Chim. France, 4. ser., 1–2 (1907), No. 9, pp. 497–501*).—The authors have made a study of the seeds of about 60 species of leguminous plants, representing more than 40 genera, and report that most of them contain the diastase emulsin, which is capable of hydrolyzing vicianin. The glucosid, however, is only found in species of the genus Vicia and in not all of the species of that genus. It was found that *Vicia narbonensis* did not contain either the diastase or vicianin.

The Leguminosæ of Porto Rico, JANET PERKINS (*U. S. Nat. Mus., Contrib. Nat. Herbarium, 10, No. 4, pp. 133–220 + IX*).—Descriptions are given of the species of leguminous plants known to occur in Porto Rico, and their distribution throughout the West Indies is indicated. Sixty-seven genera and 141 species are described, and notes are given on the uses of such as are known to have economic value.

Sumac and its sophistication, E. COLLIN (*Jour. Pharm. et Chim., 6. ser., 25 (1907), No. 12, pp. 603–610, fig. 1*).—A description is given of true sumacs which are said to consist of the leaves of *Rhus coriaria* and *R. cotinus*, and attention is called to a number of varieties of leaves commonly used in the falsification of these tannin materials. Among the more common are inferior varieties of Rhus, such as *R. glabra* and *R. metopium*, and the leaves of *Pistacia lentiscus*, *Tamarix africana*, *Coriaria myrtifolia*, *Osyris compressa*, and *Ailanthus glandulosa*.

FIELD CROPS.

Farm practice in the Columbia Basin uplands, B. HUNTER (*U. S. Dept. Agr., Farmers' Bul. 294, pp. 30, figs. 9*).—A description of the region and its types of soil is given, its agricultural history outlined, and the cropping systems followed described. The most important varieties of spring wheat grown in that section are Little Club, Red Chaff, Jenkins, Early Wilbur, and Bluestem, and the most important varieties of winter wheats are Red Russian, Jones Fife, Fortyfold, and Turkey Red. Each one of these varieties is briefly noted.

The best method of summer fallowing consists in disking and harrowing in the early spring before plowing, packing the subsurface immediately after plowing, and then giving sufficient surface cultivation to retain moisture and keep the weeds under control. Where this method is practiced, the yields of wheat are about 25 per cent greater than those obtained by ordinary summer fallowing. It was observed that the use of implements for settling and packing the bottom of the plow furrow tends to increase materially the yield of all cereal crops when the land is plowed in the spring before it is sown.

It is also stated that farmers as a whole will secure better results by confining themselves to a few varieties of wheat. Little Club and Red Chaff are best adapted to humid sections and Bluestem to arid and semiarid conditions. Early Wilbur, a new wheat, is promising in the arid section because of its earliness. Of the winter wheats Turkey Red stands first for the arid and semiarid sections. When the grains are hard and horny it is a very superior milling wheat, but on account of its tendency to become starchy it may be necessary to procure seed wheat occasionally from Kansas and Nebraska. Fortyfold is adapted to the entire region, stands the winters well, and has the advantage of being early.

Dry farming in Montana, F. B. LINFIELD and A. ATKINSON (*Montana Sta. Bul. 63, pp. 32, pl. 1, figs. 8, maps 2*).—The first part of this bulletin describes the districts where dry farming promises greatest success in Montana and the second part describes the principles and practices of dry farming.

In connection with the descriptions of the different districts the rainfall of the various sections is discussed and the amount of precipitation recorded. Historical notes on dry land cropping are given and the statement is made that in any portion of the State having 14 in. of rainfall or more, and where the precipitation for the months of April, May, June, and July is 7 to 8 in. or over, dry farming properly conducted ought to be successful, but that those areas with an average of 12 in. or less of annual rainfall, and with less than 7 in. in the spring and early summer months, offer a less promising outlook.

In discussing the principles and practices of dry farming the results gained from actual tests made in the State are presented. The following cultural methods have been found of value: The formation of a deep seed bed as a soil moisture reservoir, careful packing of the soil, constant surface cultivation when possible, summer fallowing each alternate year together with summer cultivation, growing hardy strains of the different crops, growing fall and early ripening strains of spring grain, thin seeding, growing intertilled crops like corn and potatoes, as constant cultivation retains soil moisture, and occasionally growing a leguminous crop.

The average yields per acre on 5 dry farms in 1906 were as follows: Durum wheat 14.63 bu., Sixty Day oats 27.45 bu., White Hulless barley 20.86 bu., spelt 19.60 bu., spring rye 14.90 bu., fall rye 25.15 bu., flax 8.72 bu., sugar beets 5.50 tons, potatoes 95.53 bu., and corn 42 bu. As determined on 3 of the farms sowing 3 pk. per acre of spring wheat or of oats gave better yields than either 5 or 8 pk., and 3 pk. of barley gave a better yield than 5 pk.

Forage plants at the Highmore substation, 1906, W. A. WHEELER and S. BALZ (*South Dakota Sta. Bul. 101, pp. 131–153, figs. 5*).—The seasons of 1905 and 1906 were favorable to the production of large crops of corn and forage. Of the different alfalfa plants tested Nos. 162, 164, 167, and 240 have been found hardy and of high forage quality under conditions at Highmore. Nos. 162 and 167 started earlier in the spring and produced a stronger first crop than Nos. 164 and 240. These 4 numbers have been tested from 8 to 10 years and with the exception of No. 240 have gone through several generations of seed. About 20 numbers of strains grown in the breeding plats as well as in ordinary field tests are described.

It was observed in the pedigree rows of 1906 that plants from the same selection had a general tendency towards uniformity, and that some rows exhibited exceptional forage qualities as compared with plants in other rows, while other pedigree rows showed great seed-bearing tendencies. Five kinds of alfalfa sown in 1905, of which Montana, Arabian, and Turkestan survived the following winter, produced 2,860 lbs. of hay per acre. In this set Oasis and Tripoli were killed out entirely, while Arabian sustained a loss of 75 per cent through winterkilling as compared with only 5 per cent for the other 2 varieties.

Of the different varieties of millet, Kursk, introduced by this Department, appears to be as well adapted to South Dakota as any other variety tested, and some of the pedigree stocks from this source are very promising. Of the broom corn or proso millets, Voronezh or Black Turkestan and Tambov have given the best yields and appear to be well adapted to the region between the James and Missouri rivers in South Dakota and possibly west of this region. Seed of Red Orenburg and Black Voronezh grown at Highmore yielded better than seed from other sources.

The results with 16 varieties of corn under trial show that Minnesota No. 13 still leads in quality and yield, although Golden Ideal in 1906 produced 3.7 bu. more per acre than this variety. Golden Ideal, however, required 6 days longer for maturing, had a larger percentage of cob, and contained more water. Of the Dent corn varieties tested at Highmore in 1906 only Minnesota No. 13, Early White Dent from North Dakota, and Brown County Yellow Dent seem worthy of extended trial.

Notes are also given on the value of 3 sorghums tested for the past 3 years, but owing to a poor stand in 1906 no comparisons were made.

Report on the northern substations for 1906 [Field crops], E. J. DELWICHE (*Wisconsin Sta. Bul. 147, pp. 1–15, 20–24, 27–48, figs. 8*).—This bulletin contains the report on the first season's work carried on at the substations located at Ashland, Iron River, Bayfield, and Superior. The Ashland and Superior experiment farms are located on red clay, and the Iron River farm on red sandy soil typical of much of the sandy soils of northern Wisconsin. The purpose of these experiments is the introduction and examination of farm crops, the dissemination of suitable standard seeds, the determination of varieties adapted to the region, and the development of such agricultural industries and practices as are adapted to the conditions.

At Iron River, Oderbruck barley was sown at the rate of 5 pk. per acre on April 30. A crop of 26 bu. of grain per acre was threshed in September, the weight per measured bushel being 49.2 lbs. Nine pecks per acre of Swedish Select oats was sown May 1, from which a yield of 27 bu., weighing 38.6 lbs. per measured bushel, of oats of a fine quality was secured. Early Yellow Dent corn planted from June 2 to 7 was harvested the first days in October. The yield of the 2 acres first planted was 47.7 bu. of shelled corn per acre, and the total yield of green corn was 18,500 lbs. per acre.

Soy beans planted June 12 were cut for hay September 10. The yield of hay was at the rate of 3,828 lbs. per acre. A row of beans left uncut to ripen was killed by frost October 12. Kleinwanzleben sugar beets planted May 30 were harvested October 26, giving a yield of 9 tons per acre. The sugar content was 16.9 per cent and the purity 93.3 per cent. Alfalfa was sown at the rate of 25 lbs. of seed per acre on May 2. The alfalfa grew to the end of the season and stood from 6 to 7 in. high.

At Ashland, on clay soil, Oderbruck barley sown May 10 at the rate of 7 pk. of seed per acre was harvested August 10. The crop was heavy in straw, stood up well, and free from rust or smut, and the yield per acre was 22½ bu. This first plat was on fall plowing. The spring plowed plat, although better drained than the first, yielded only 10 bu. per acre. Swedish Select oats were sown May 16 and 20 at the rate of 2 bu. of seed per acre. The early sowing produced a good stand but was attacked by rust and yielded only 16 bu. per acre. The later sown oats did not reach maturity. A good patch of clover was secured with the oats as a nurse crop and a still better one with the barley. White Flint corn planted July 11 had produced fully developed ears in the milk stage by September 8 and was cut for fodder early in October.

At Superior, Swedish Select oats on a stiff red clay loam, rather mucky in the lowest places and poorly drained, produced only 9 bu. of grain of poor quality.

Potatoes were planted at Iron River on 4 different plats. The first was manured with well-rotted barnyard manure at the rate of 10 loads per acre. The second received 200 lbs. of sodium nitrate, 300 lbs. of desiccated bone, and 200 lbs. of potassium sulphate per acre. The third was left as a check, and on the fourth a crop of clover was turned under. The barnyard manure plat yielded 197 bu. 14 lbs., the commercial fertilizer plat 192 bu. 23 lbs., the check plat 174 bu. 53 lbs., and the clover plat 241 bu. 36 lbs. per acre. It was also shown that potatoes should not be raised two years in succession on the same land, and that nitrogen at present seems to be the only fertilizer element needed to produce a good crop of potatoes on these sandy soils. This type of soil seemed well adapted to the potato and clover growing is the cheapest method of supplying the soil with the needed nitrogen.

Other experiments on sandy soils with corn and potatoes seemed to show that peat in combination with rock phosphate and potassium sulphate is an effective substitute for barnyard manure. Acid phosphate apparently gave a decided increase in yield, while lime also gave an increase, but not in any marked degree. The principal needs of this type of soil are nitrogen and humus, of which peat is a cheap source. The results of experiments with green manuring crops showed that the cowpea, hairy vetch, soy bean, and crimson clover were best adapted to that kind of soil.

Notes are also given on experimental work conducted on the red clay soils with barley, oats, and corn, and with rotations and fertilizers. The effect of tile drainage was observed to be beneficial to the different crops, but with oats the effect was not so pronounced as with barley. Corn gave a better crop on tiled than on untiled land, and the best results were obtained where the tiles were placed 40 ft. apart.

Small grain crops, A. M. Ten Eyck and V. M. Shoesmith (*Kansas Sta. Bul. 144, pp. 141–193, figs. 5*).—A trial of varieties of winter wheat is described in detail. Hardy strains of durum wheats sown in fall were nearly all destroyed, while ordinary winter varieties survived the winter in good condition. Observations made in 1904 on the yield in connection with stooling showed that those varieties averaging 6 or more tillers per plant made an average yield of 28.45 bu. per acre, while those averaging less than 6 produced 21.74 bu. The varieties yielding 27 bu. or more per acre averaged 6.6 tillers per plant, while those yielding less than 27 bu. averaged 4.85 tillers per plant. In 1905 stooling apparently had little or no effect upon the yield. In 1906 varieties averaging 7 or more tillers per plant made an average yield of 43.62 bu. per acre, and those averaging less than 7 a yield of 45.51 bu. In 1904 the varieties tillering the most made the largest yields, while in 1906 the reverse took place, indicating that the yield depends upon the thickness of the stand, but that the proper thickness may vary with the season.

In 1904, 2 varieties of soft wheat gave an average yield of 27.2 bu., 15 varieties of the smooth bearded type of hard wheats 28 bu., 2 varieties of the smooth awnless type 19.8 bu., and 2 varieties of awnless velvet chaff 10.4 bu. per acre. During the 3 years the varieties of the hard red Turkey or Russian type of wheat were the best yielders. The highest average yield for the 3 seasons, 41.7 bu. per acre, was made by Bearded Fife, really a hard red Turkey wheat. Other varieties tested for 3 years and producing large average yields were Defiance, Turkey No. 4, Turkey No. 9, Malakoff, and Kharkof of the hard wheats, and Zimmerman and Fultz of the soft wheats. The 2 soft wheat varieties averaged 38.3 bu. per acre, as compared with 37.88 bu. for the 11 hard wheats tested during the same period. It is stated that the hard wheats are especialy adapted to fairly dry or upland conditions, such as obtain in the western two-thirds of the State and on the uplands in the eastern part, while the soft wheats give best results in eastern Kansas on bottom lands and in some sections on the lower uplands.

A selected strain of winter durum wheat produced 42.56 bu. per acre in 1904, as compared with 17.52 bu., the largest yield from spring durum wheat. The following year, however, only about one-tenth of the plants of this strain survived the winter.

In 1906 the best results were secured from planting wheat in furrows 2 to 2½ in. deep. Seeding winter wheat at weekly intervals from September 1 to November 3 resulted in the best yields on the plats sown September 21 and 27 and October 5. The use of 5 pk. of seed per acre gave the largest yield as compared with other quantities of seed. In previous tests, seeding 6 to 8 pk. per acre has given the best results.

A yield of 59.09 bu. per acre was secured on a ½-acre plat. This high yield is regarded as resulting from a good rotation of crops, the application of barnyard manure in moderate quantities, early plowing and frequent cultivation of the soil, seeding at a favorable time, and the use of a well-bred variety. In this same field a measured acre produced 3,497.6 lbs., or 58.3 bu. of wheat.

In a fertilizer experiment it was shown that commercial fertilizers on worn land, deficient in humus and in bad physical condition, are practically a total loss. In all fertilizer tests with small grains conducted at the station the application of barnyard manure has resulted in the largest yields. For green manuring the cowpea was found to be an excellent crop. It was found, however, that corn is a much better crop than wheat to follow cowpeas.

Wheat was grown in a 2-year rotation, being alternated with wheat, oats, flax, millet, soy beans, sorghum, Kafir corn, and corn. The value of the crops for a 4-year period was greatest when wheat was rotated with oats, and next greatest when wheat was grown continuously.

In 1904 winter barley, owing to winterkilling, gave a low yield, but in 1905 2½ acres yielded 67.86 bu. per acre. In 1906 a yield of 66.9 bu per acre was secured from a variety originally obtained from the Tennessee Station. As compared with other grains winter barley yielded nearly 75 bu. more grain per acre in the 3 years than spring barley and 40 bu. more than the best producing oats. The barley sown on September 21 and 27 gave better results than that sown either earlier or later. Seeding 2 bu. per acre produced a heavier yield than either smaller or larger quantities of seed.

Monster winter rye grown for 3 years successively gave an average yield of 37.97 bu. per acre. Ivanof winter rye, a Russian variety, appeared a little hardier and a stronger growing rye than Monster. The average yields for the 2 seasons, 1904 and 1905, were about the same.

Of the varieties of winter oats tested at the station, Winter Turf seemed more hardy than Virginia Gray, Common Gray, and Culbertson. In the fall of 1904, 2 samples of Winter Turf oats were sown, the first yielding 57.37 bu. and the second 44.05 bu. per acre, while on another field Red Texas oats yielded 71.26 bu. per acre. The following year the winter oats winterkilled very badly, only a few plants surviving. The seed from these was harvested for further planting and the selection of hardier strains. The Winter Turf oats stooled abundantly and made a rank growth of foliage.

In experiments with spring wheat Velvet Don durum wheat, as an average for 4 years, yielded 14.24 bu. per acre, while the best producing variety of winter wheat yielded 41.70 bu. The durum wheats yielded better than the common varieties of spring wheat.

The highest average yield during the 4 years' comparison of varieties of oats, which was 43.24 bu. per acre, was produced by Sixty-day, and the second highest yield, 42.11 bu. per acre, by Kherson, two of the earliest maturing varieties grown. Red Texas ranked third, with an average yield of 40.44 bu. per acre. In 1905 and 1906 the average highest yields were as follows: Red Texas 54.37 bu., Silvermine 52.18 bu., White Tartar 51.97 bu., Danish 48.03 bu., Kherson 47.27 bu., Sixty-day 46.75 bu., Minnesota No. 202 46.57 bu., and Swedish Select 45.16 bu. per acre.

During the 4 seasons' work with varieties of barley, Common Six-rowed barley made the largest average yield, 30.94 bu. per acre, Bonanza and Mansury ranking second and third, with yields of 28.97 and 28.80 bu. per acre, respectively. Beardless varieties produced smaller yields with a poorer grade of grain than varieties of the six-rowed bearded type. Hulless barley produced relatively low yields. In general, the largest yields from different rates of seeding barley and oats were secured from the use of 2½ bu. of seed grain per acre. The yields of grain on brome sod land, however, were not only larger than those produced on corn ground and alfalfa land but the largest crop was also secured from sowing 1½ bu. of seed barley per acre. The brome sod land produced nearly 25 bu. more per acre than the alfalfa land and 11.3 bu. more per acre than the corn ground. This result was largely due to the lodging of the grain where the crop followed the alfalfa and corn. In 1905 the best yield of oats, as well as of barley, was secured from seedings made March 30. In 1906 barley and oats were sown on 7 different dates from February 1 to May 11. The largest yield of barley, 36.55 bu., was produced by seeding February 1, but the largest yield of oats, 43.75 bu., was secured from the seeding made March 29. The seeding of different small grains on February 1, February 19, and at the ordinary season showed that spring wheat, emmer, and barley gave decidedly larger yields from the early or winter seeding, while oats, winter wheat, and winter rye were most satisfactory when sown at the ordinary season.

Nitrate of soda was applied at the rate of 180 lbs. per acre for oats and 210 lbs. per acre for barley. The oats lodged badly on both the fertilized and unfertilized plats. The fertilized plat produced 19.5 bu. of grain and 1,512 lbs. of straw, and the unfertilized plat 24.4 bu. of grain and 1,649 lbs. of straw per acre. The fertilized barley plat gave 20 bu. of grain and 2,234 lbs. of straw per acre, and the check plat 16.2 bu. of grain and 1,640 lbs. of straw per acre. The following year the experiment was repeated, nitrate of soda being applied to both oats and barley at the rate of 186 lbs. per acre. The fertilized plat of oats yielded 24.17 bu. of grain and 1,637 lbs. of straw, and the check plat 26.27 bu. of grain and 1,602 lbs. of straw per acre, while the fertilized barley plat produced 35.21 bu. of grain and 1,594 lbs. of straw, and the unfertilized plat 17.69 bu. of grain and 819 lbs. of straw per acre. In another series of experiments with commercial fertilizers a combination of the fertilizers gave practically no better results than the application of each on separate plats. A crop of cowpeas preceding the oat crop but not plowed under for green manure was much more effective in increasing the yield than the use of commercial fertilizers. Applying commercial fertilizers at different rates on poor upland soil proved of very little effect in increasing the crops of grain, whether applied in small or large quantities.

Spring emmer was tested for 3 years, one variety received from a Kansas seed firm giving an average yield for the 3 seasons of 28.46 bu. per acre, while another received from the North Dakota Experiment Station produced 31.35 bu. per acre. Fall seeding of emmer with the purpose of producing a winter variety proved unsuccessful. Seeding emmer at the rate of 1.87 bu. per acre through the use of an ordinary grain drill set to sow 2½ bu. of barley per acre produced the largest yield as compared with other quantities. A yield of 2,571 lbs. of spelt per acre is also recorded.

The varieties of flax producing the largest average yields in 1905 and 1906 were as follows: Common flax No. 14, 11.58 bu.; U. S. Department of Agriculture No. 9982, 10.82 bu.; North Dakota No. 155, 9.78 bu.; North Dakota No. 709, 9.15 bu. per acre. The best average yield of grain was secured by seeding at the rate of 3 pk. per acre. The thickest sown flax, 5 pk. of seed per acre, produced the largest quantity of straw, 4,723 lbs. per acre. The next largest yield, 4,633 lbs., being obtained from the plats seeded with 3 pk. per acre. A brief note on flax culture in Kansas is also given.

A preliminary progress report of cereal investigation, 1905–1907, G. W. SHAW (*California Sta. Circ. 28, pp. 4*).—The object of this work is to discover or produce such wheat as will yield the largest profit per acre and supply grain of superior milling quality, to conduct similar experiments with oats, barley, and other cereals, and to determine the effects of various methods of culture and of changes of environment upon the growth of cereals and particularly the wheat kernels.

The act passed by the State legislature to provide for the improvement of the cereal crops of California is given, and the arrangements for the work and the plan of operation are discussed. The grains introduced into California in connection with this work and not before grown in the State are listed. With the exception of corn and a very few varieties of other grains the entire list of varieties was planted at Modesto and Yuba City, the 2 field stations established for these investigations.

Cowpeas and soy beans, L. A. MOOREHOUSE (*Oklahoma Sta. Bul. 74, pp. 22, figs. 5*).—General descriptions of the cowpea and the soy bean are given and their value, especially in crop rotations, is pointed out.

Rotation experiments with these crops have been in progress at the station for several years. One rotation included corn, oats, and wheat and cowpeas, covering a period of 3 years, wheat and cowpeas being taken from the land in one season. In this test the plats receiving barnyard manure at varying intervals gave an average yield of 3.23 bu. of grain and 0.35 ton of straw per acre, while the unmanured ground gave 2.88 bu. of grain and 0.29 ton of straw as an average yield. This low yield of the cowpea crop was due to a poor stand resulting from the seed not giving a good germination. The second rotation included castor beans, Kafir corn, cotton, oats, and wheat and soy beans, the series being completed in 5 years, with crops of wheat and soy beans in the final year. The manured section received barnyard manure at the rate of 14 tons per acre in the spring of 1902, with no further application of any kind since that date. After the wheat was harvested in June, 1904, all plats were disked twice and a third disking was given about the first of July after heavy rains had fallen. The plats were seeded to soy beans on July 12 and 13 in drills 32 in. apart at the rate of about 30 lbs. of seed per acre. The unmanured plats yielded 11.6 bu. of beans and 0.68 ton of straw, and the manured plats 17.6 bu. of beans and 1.02 tons of straw per acre. This crop matured in 79 days.

In a variety test with cowpeas, conducted in 1903, Whip-poor-will produced a more vigorous growth of vines and gave a larger yield than California Black Eye. The Iron cowpea gave a heavy yield of forage but a low yield of grain. In 1904, 5 varieties of cowpeas were compared, and in this test the White Era led in yield of grain with 18.20 bu. per acre, a local variety somewhat resembling Whip-poor-will standing next with 13.59 bu. The Iron cowpea gave the maximum yield of cured hay, with a low yield of seed. California Black Eye ranked first in earliness, requiring only 112 days to mature, while the other varieties continued to grow and blossom for 142 days.

In 1904 cowpeas and soy beans were compared on bottom and on upland soil. The bottom land was seeded May 5 and the upland June 30. On the bottom land the soy beans produced 0.70 ton of hay and 9.90 bu. of grain, and the cowpeas 1.79 tons of hay and 8 bu. of grain per acre. On the upland area soy beans produced 0.61 ton of hay and 9.45 bu. of grain, and cowpeas 1.07 tons of hay and 12.45 bu. of grain per acre.

Root crops for stock feeding, S. FRASER, J. W. GILMORE, and C. F. CLARK (*New York Cornell Sta. Bul. 243, pp. 47-76, figs. 15*).—This bulletin deals with mangels, sugar beets, turnips, hybrid turnips, ruta-bagas, kohl-rabi, carrots, and parsnips, with a view to guiding those wishing to raise any of these crops under New York State conditions. The value of root crops for forage is discussed and the cultural experiments conducted for 3 years are reported.

In 1904 the crops were sown early in May and the middle of June on land part of which had been in mangels for 3 years and the remainder under a rotation of crops. The early sown mangels on the no-rotation areas were attacked by leaf spot while young. The land received about 10 tons of barnyard manure per acre, was plowed about 8 in. deep early in the spring, and harrowed 4 times. Four hundred pounds of 17 per cent available acid phosphate was sown broadcast and harrowed in. The land was rolled before sowing and the seeds put in with a hand planter. The mangels were sown at the rate of about 8 lbs. of seed per acre. Mangel and parsnip seeds were put in about ¾ in. deep and all others ½ in. deep. The mangels came up in 12 days and the cabbages, ruta-bagas, hybrid turnips, and common turnips in from 5 to 6 days. The carrot seed was slow in starting and the parsnips were a failure. The ruta-bagas were sown at the rate of 4 lbs., hybrid and common turnips rather less, and carrots at the rate of 6 to 7 lbs. per acre. The cultivation for all crops was the same. . The hand cultivator was used twice in May and the 1-horse cultivator on May 20 and every 2 weeks during June and July, and in the case of the late-sown crops until August or until the plants met in the row. Common turnips were harvested July 18 and all other roots from October 22 to 29.

Sugar beets were also grown with and without rotation on a well fitted, rich loam soil. This was replowed and fertilized with 1,000 lbs. per acre of a mixture containing 4 per cent nitrogen, 5 per cent phosphoric acid, and 10 per cent potash. In addition 1,500 lbs. per acre of air-slaked lime was applied. The seed used was of the Kleinwanzleben variety, grown at Fairfield, Wash. The seed was sown ½ to ¾ in. deep at the rate of 12 lbs. per acre. The plants were thinned 6 to 8 in., and the rows were 27 in. apart. Harvesting was begun Sept. 13 and continued weekly until Nov. 1.

In 1905 the experiment was conducted on clay loam soil in poor condition, which in 1902 and 1903 had produced oats, and in 1904 soy beans. The land was manured in the fall with from 10 to 12 tons of cow manure per acre. It was plowed 8 in. deep from May 2 to 5. It was harrowed and limed with about 1,200 lbs. of unslaked freshly burned lime per acre. The lime was slaked to a fine powder and then spread and harrowed in, after which a dressing of 240 lbs. of 12 per cent available acid phosphate, 120 lbs. of 16 per cent available dried blood, and 120 lbs. of muriate of potash was given.

In 1906 the soil used for this work was a Dunkirk clay loam which had been in corn in 1905 and in timothy for several years previous. It was plowed in the fall and limed, and manure was applied at the rate of 10 tons per acre. It was brought to a good tilth the next spring and given an application per acre of 120 lbs. of dried blood, 240 lbs. of acid phosphate, and 120 lbs. of muriate of potash. The seeds were sown on May 15 and 16. No late sowing was made, as the results of the 2 previous years were not favorable to late sowing.

A summary of the results for the 3 years is given in the following table:

Yields per acre of fresh and dry substance of different root crops.

Crops.	1904.		1905.		1906.		Average.	
	Fresh substance.	Dry substance.	Fresh substance	Dry substance.	Fresh substance.	Dry substance.	Fresh substance.	Dry substance.
	Tons.	*Pounds.*	*Tons.*	*Pounds.*	*Tons*	*Pounds*	*Tons*	*Pounds.*
Mangels	20.8	4,726	26.2	5,800	23 9	4,940	23.6	5,155
Half-sugar mangels			29.6	6,580	23.6	5,180	26.6	5,880
Sugar beets			26.9	8,120	20.7	6,060	23 8	7,090
Carrots	9.6	3,181	16.8	3,720	11 3	2,500	12.6	3,134
Ruta-bagas	17.1	3,074	25.8	4,820	26 0	5,100	23 0	4,331
Hybrid turnips	21.4	3,561	24 7	4,120	18.1	3,400	21 4	3,694
Turnips	5.6		20.9	3,380	12.1	1,980	12.9	2,680
Kohl-rabi			22.3	4,480	20.0	3,660	21.2	4,070
Cabbages	43.8	6,206	29.0	3,640	22.5	4,140	31.8	4,662
Parsnips			8.0	3,240	8.1	3,020	8.1	3,130

Sugar beets gave the highest average yield of dry matter, but the difficulty of harvesting them seems to offset this advantage. Mangels and half-sugar mangels stood next in yield of dry matter and were closely followed by ruta-bagas and cabbages. It is stated that the greatest economy would be practiced by growing cabbages, ruta-bagas, and mangels in succession for harvesting and feeding, more especially for sheep and swine. The results show that a profitable yield of stock feed may be harvested in average seasons from practically all of these crops and that a greater average yield of dry matter may be obtained from mangels, half-sugar mangels, sugar beets, and ruta-bagas than from an average yield of corn, although at not quite so low a cost. Mangels proved more succulent than sugar beets, were easier to harvest, and also kept better during storage. Turnips are considered useful for early feeding, but were found not to yield as well as the other roots and were more liable to be attacked by disease. The yields of carrots and parsnips were not sufficiently large to warrant general planting for stock feeding. Notes on harvesting, storing, and feeding roots are given.

Culture and varieties of roots for stock feeding, S. FRASER, J. W. GILMORE, and C. F. CLARK (*New York Cornell Sta. Bul. 244, pp. 79–122, figs. 29*).—This bulletin discusses the culture of roots, describes the leading varieties, and reports the experience gained with this class of crops at the station.

The number of seeds or fruits per pound of the different kinds of seed, as well as the percentage of germination, were determined, and the results are summarized in the following table:

Comparison of root crop seeds.

Crop.	Seeds or fruits per pound.	Germination.
		Per cent.
Mangels	32,000 to 185,000	73 to 185
Half-sugar mangels	24,000 to 36,000	100 to 136
Sugar beets	22,000 to 24,000	102 to 132
Ruta-bagas	161,000 to 188,000	83 to 92
Hybrid turnips	183,000 to 266,000	71 to 94
Common turnips	200,000 to 260,000	89 to 92
Kohl-rabi	114,000 to 129,000	48 to 96
Carrots	440,000 to 460,000	15 to 83

Carrot seed with a germination power of only 15 per cent was sown, and for each carrot secured over 80 seeds were required. Sowing from May 6 to 9 proved better for all roots than sowing as late as June 12. On clay loam soil carrot seed failed to grow when sown ¼ in. deep, while it grew well in sand sown ⅝ in. deep. Mangels, half-sugar mangels, and sugar beets were all sown ¾ in. deep, and all others between ¼ and ½ in.

Mangels were ready for thinning 30 to 35 days after sowing, ruta-bagas 25 to 30 days, turnips 16 to 25 days, and carrots and parsnips 35 to 40 days. An application of 100 lbs. of nitrate of soda per acre was made when the crops were found to be making insufficient growth. Common turnips, some of the hybrid turnips, and cabbages were used from the beginning of September until November, and the other crops were harvested and stored in October and early in November.

Proper rotation, early sowing, and a uniform stand are regarded as essentials for a high yield. Mangels grown continuously on the same land for 4 years yielded 9.6 tons of roots, containing 1 ton of dry matter, while on land under rotation they yielded 34 tons of roots and 4 tons of dry matter per acre. From 25,000 to 30,000 plants of mangels, ruta-bagas, and hybrid turnips, and from 40,000 to 60,000 plants of carrots per acre are suggested as a proper stand.

Two half-sugar mangels, Vilmorin Half-sugar Rosy and Carter Half-sugar, are considered suitable stock for breeding purposes. Carter Holborn Elephant, Kangaroo, and Garton Superlative ruta-bagas were found to be comparatively free from fibrous roots and of uniform and good shape. The Yellow Aberdeen hybrid turnip proved best for early fall use, while Garton Pioneer is later and can be stored as well as ruta-bagas. Mammoth Improved Green Globe and White Egg turnips were the best early varieties. Carter 100-ton carrot was the best variety for clay loam soil. Lobberich Agricultural carrot grew equally well on clay loam and gravel loam, and Giant Wiltshire and Orange Giant gave good yields on heavy clay land. Owing to difficulty in harvesting, the Giant Wiltshire and Orange Giant are better adapted to deep friable loams than to soils of a heavier nature. White Vienna and Carter Model kohl-rabi gave about equally good results.

With mangels, the average yield of dry matter per acre in the past 3 years was between 2.4 and 3 tons per acre. In 1904 the dry matter in the 9 varieties grown varied between 9.56 per cent and 16.1 per cent. Norbiton Giant was near both extremes, with 9.55 per cent in one case and 14.88 per cent in another. The sugar content for this same year varied with the 9 varieties between 4.23 per cent and 8.99 per cent. In sugar content the Norbiton Giant also showed a wide variation, although one sample ranked first.

It was also observed that mangels and sugar beets when grown continuously on the same land for 4 years were much more susceptible to leaf spot than when grown in a rotation with other crops. The results secured with 5 varieties of mangels with and without rotation showed a gain of 24 tons in total yield and of 3 tons in dry matter per acre as apparently due to rotation with other crops. In the case of sugar beets the results showed a gain of 1.9 tons in total yield or 21 per cent, and ½ ton of dry matter or 24 per cent increase per acre in favor of rotation. The increase in the dry matter was entirely in sugar, which increased 45 per cent. Data are brought together showing the composition of mangels since 1852 and pointing out that the average composition of the mangel to-day is practically the same as it was 50 years ago. Attention is called to the fact that during the past 40 years the value of the sugar beet for sugar production has been increased 50 per cent.

Alfalfa in Indiana, A. T. WIANCKO (*Indiana Sta. Bul. 122, pp. 141–154*).—The first part of this bulletin gives the results of experiments in late summer seeding, and the second part presents suggestions for beginners in alfalfa culture.

On the university farm in 1905 alfalfa was seeded August 17, a good growth was secured, and the young crop passed the winter successfully. In 1906 an effort was made to determine the practicability of late seeding by similar experiments in various parts of the State. Arrangements were made and tests were reported from 57 different farms located in 42 different counties. The reports showed good results with various dates of seeding all through the month of August. Of 38 plats sown from August 7 to 15, 34 gave satisfactory fall growth and 19 of these were in good or fair condition at the end of April. Of 19 plats sown later than August 15, 12 gave a satisfactory fall growth and 10 of these were in good or fair condition at the end of April. Of 57 reports 30 consider that the fall weather was favorable, and of the 44 reporting good stands 16 say that the fall weather was rather too dry and 5 very dry. The reports do not seem to show any relation between the date of seeding and the amount of winterkilling. Of 52 experimenters reporting on the spring condition, 23 reported less than 10 per cent of damage by winterkilling, 11 from 10 to 30 per cent, and 18 over 30 per cent. In some cases the damage was largely due to standing water and ice. There was more or less winterkilling on all types of soils, but relatively less on the lighter soil.

It is also shown that of 13 tests on pure clays all gave good or fair stands, of 38 tests on clay or clay loam soils 28 gave good or fair stands, and of 15 on sandy or sandy loam soils 14 gave good or fair stands. The preceding crop had no appreciable effect upon the results except that standing corn seemed to act unfavorably. In many cases the use of either manure or commercial fertilizers for the crop proved of considerable value. Observations on the presence of nodules and on the practice of inoculation indicated that some special form of inoculation is probably necessary in one-half of the cases where alfalfa is first introduced.

The improvement of corn, A. M. SOULE and P. O. VANATTER (*Virginia Sta. Bul. 165, pp. 91–185, figs. 48*).—The first part of this bulletin is devoted to the improvement of corn, and the second part to the basis for this improvement.

Among the best varieties of corn tested at this station are Boone County White, Cocke Prolific, Snow White Dent, Virginia Station Leaming Ear No. 37, and Virginia Golden Dent, these having made yields respectively of 78.57, 77.68, 75.89, 75.89, and 71.43 bu. per acre. Leaming is considered one of the best varieties for high elevations, and Hickory King for soils of medium fertility. The period of tasseling with the 20 varieties under test commenced July 1 and ended July 31, and the period of silking commenced July 6 and ended August 12, the number of days varying from 9 to 24. The benefits of detasseling did not pay for the labor. While varieties from the Middle West will outyield home-grown strains under proper soil conditions, they will not do so well on the comparatively thin lands of the State as the native varieties.

In 1906 a variation in yield per acre of more than 9 bu. between the best and poorest strains of Hickory King and nearly 18 bu. between similar strains of Virginia Ensilage was observed. A sample of Leaming corn from Illinois yielded 76.34 bu. and a Virginia sample 59.81 bu. per acre. Ear No. 14 from the breeding plat made a yield of 59.82 bu., Ear No. 35, 66.29 bu., and Ear No. 37, 67.84 bu. per acre. These results are pointed out to show the importance of securing the right strain.

It was found that corn developed on thin land will not yield well when first placed on rich ground. Virginia Leaming on land where cowpeas were plowed under yielded 59.81 bu., as compared with 76.34 bu. for a thoroughbred sample from Illinois. Ear No. 37, a strain improved at the station, made a yield of 64.34 bu. These results indicate that corn from the West should be put on rich land and the native corn bred up by crossing to produce corresponding yields under favorable conditions.

The application of fertilizers where cowpeas and barley or cowpeas alone were turned under was not profitable as a rule. The most profitable fertilizer application when green manure was also used was acid phosphate at the rate of 150 to 300 lbs. per acre and muriate of potash at the rate of 50 lbs. Green manuring with leguminous crops was highly beneficial, but heavy applications of fertilizers seemed advisable where vegetable matter was lacking in the soil. Where wheat stubble was plowed under in the fall 15 tons of barnyard manure gave an increase per acre of 27.91 bu. over no fertilizer, at a cost of 21 cts. per bu., 300 lbs. of cotton-seed meal an increase of 31.93 bu. at a cost of 14 cts., acid phosphate at the rate of 150 or 300 lbs. an increase of 9.16 and 18.33 bu., respectively, at a cost of 10 cts., Thomas slag at the same rates, of 10.54 and 14.99 bu. at a cost of 13 and 18 cts., respectively, floats at the rate of 300 lbs., of 5.59 bu. at a cost of 18 cts., muriate of potash, of 16.75 bu. at a cost of 6 cts., and a complete fertilizer at the rate of 100 lbs. nitrate of soda, 300 lbs. of acid phosphate, and 50 lbs. of muriate of potash made an increase of 16.30 bu. at a cost of 33 cts. per bu.

The necessity and possibility of improving corn is shown by the fact that the yield from 40 samples tested varied from 28.14 to 57.26 bu. per acre in 1905, and from 34.79 to 81.69 bu. in 1906. The effect of cross-pollinating native varieties with western strains is shown in Ear No. 23, which yielded 47.73 bu. in 1905 and 79.46 bu. in 1906, and in Ear No. 35, which yielded 54.94 bu. in 1905 and 81.69 bu. in 1906. The effect of cross-pollination was further shown by the fact that the lowest yield from Illinois seed in 1905 was 26 bu. and the highest 53 bu., while in 1906 the lowest was 42 bu. and the highest 68 bu. In 1905 the lowest yield of the Virginia sample was 39 bu. and the highest yield 57 bu., while in 1906 the corresponding yields were 52 and 81 bu. A Virginia sample of Boone County White after cowpeas plowed under made 84.53 bu., after 15 tons of barnyard manure 73.21 bu., and after timothy and clover sod 79.46 bu., while the Illinois sample yielded 58.92 bu. after cowpeas, 76 bu. after manure, and 67.86 bu. after timothy and clover sod. The fact that the Virginia seed germinated more vigorously and the plants grew better than the other strain is taken as pointing out the relation of acclimatization to yield.

Large ears selected from different samples of known history gave in every instance a more vigorous germination and higher yield than small ears similarly selected. In some instances the difference in yield amounted to nearly 11 bu. per acre. Corn stored in the crib showed a very poor germination as compared with corn stored in a dry room and on racks in the barn. The average per cent of protein in the native ears of Leaming corn in 1906 was 10.30 and in the Illinois ears 10.68. Many of the best yielding ears did not contain as high per cent of protein as the undesirable ones, thus indicating the necessity of not basing selection on a high protein content alone.

Sugar beet experiments during 1906, F. W. WOLL and C. W. STODDART (*Wisconsin Sta. Bul. 150, pp. 45, figs. 4*).—Experiments were conducted on 10 different farms with soils ranging from light sandy loams to heavy clays. The object of the work was to study the adaptability of types of Grant and Vernon county soils to sugar beet culture, and to investigate the system of fertilization that would produce the best results for factory purposes. A 1-acre field of sugar beets was grown on each of the 10 farms under different systems of fertilization. These fields were divided into 7 plats, Nos. 1 and 7 of which received no fertilizers; 2, 180 lbs. of potassium sulphate per acre; 3, 420 lbs. of 14-per cent acid phosphate; 4, these quantities of potassium sulphate and acid phosphate combined; 5, the same application as 4 with 300 lbs. per acre of nitrate of soda in addition, and 6, 10 tons of barnyard manure calculated to contain approximately the same amounts of fertilizer ingredients as the application on plat 5. Lime was applied at the rates of ½ and 1 ton per acre.

The results of this one season's work show that sugar beets as rich in sugar and high in purity can be produced in the southwestern part as elsewhere in the State. The general averages for the beets grown in that region were 15.49 per cent sugar and 91.6 per cent purity.

In all cases but one the largest yields of beets and of sugar were obtained on the plats receiving a complete fertilizer, with barnyard manure standing next as the cheapest application. Lime applied at the rate of 1,000 lbs. per acre produced a beneficial effect on a number of fields, and in one instance a heavy clay soil required a double application to increase the yield of beets and sugar. The results secured at each of the different farms are presented in tables.

HORTICULTURE.

Report on the Northern Substations for 1906. Horticulture, E. J. DELWICHE (*Wisconsin Sta. Bul. 147, pp. 15–20*).—The horticultural work at the Northern Substations is planned along 3 principal lines: Orchard work with regard to the adaptability of different kinds of fruit trees to the soil and climate and the development of methods of cultivation best suited to northern Wisconsin conditions, experiments with small fruits, and demonstrations and experimental work with potatoes and garden vegetables. As previously noted (E. S. R., 18, p. 1049), investigations were conducted to determine the possibility of fruit culture in the Lake Superior region of Wisconsin during 1906, as a result of which 3 trial orchards were established.

The orchard work for the first season is here reported, including a description of the site, a list of the varieties of fruit grown, and notes on the first year's growth. Plums, cherries, and apples were planted and as a whole the results for the season were satisfactory, although many of the cherry trees died. The failure of the latter trees to succeed is believed to be due partly to the trees being too far along when planted and partly to their being planted on wet ground. The work with potatoes is elsewhere noted.

Varieties of vegetables grown at the Xieng-Khouang experimental station in 1905, PIDANCE (*Bul. Écon. Indo-Chine, n. ser., 10 (1907), No. 60, pp. 150–159*).—A brief account is given of the cultural methods employed at the station, together with notes on a large number of vegetables, and small and tree fruits grown.

The parthenocarpie or virgin fruitfulness of fruit trees, R. EWERT (*Die Parthenocarpie oder Jungfernfrüchtigkeit der Obstbäume. Berlin: Paul Parey, 1907, pp. 57, figs. 18*).—The author's experiments in the determination of the relation of the productiveness of apples to the biology of the flowers were continued during the season of 1906. Previous results (E. S. R., 17, p. 1156) were corroborated, in addition to which a new phase in orchard culture is advanced, viz, the development of fruit without fertilization or "parthenocarpie."

In the present work the author describes his method of procedure, together with the experiments conducted in the artificial production of seedless fruit, both in the greenhouse and on trees growing out of doors. Although he has succeeded in producing seedless apples and pears of the size and quality of normal fruit, the hard cores are still present.

The planting of varieties showing a tendency to produce seedless fruit is believed to be advisable so that the supply of fruit may be maintained even when, for some reason or other, cross-fertilization has not taken place.

Report on the results obtained from the summer pruning of fruit trees (*Gard. Chron., 3. ser., 41 (1907), No. 1069, pp. 400–403; 406, 407*).—In order to obtain a large number of opinions with regard to the practice of summer pruning, the *Gardners' Chronicle* recently sent out a list of questions on the subject to correspondents interested in fruit culture in different parts of Great Britain and Ireland. The information thus secured is presented in tabular form.

With respect to the date of pruning, it appears that some operators commence in June and others as late as August, but the great majority in July. Plums are generally treated before apples and pears. More than 150 report satisfactory results from summer pruning, while only 35 express doubts as to the value of the practice. The results as tabulated are discussed editorially, and reference is made to the experiments conducted on the Duke of Bedford's experimental fruit farm, as noted below, which have not been favorable to summer pruning.

Seventh report of the Woburn Experimental Fruit Farm, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt., 7 (1907), pp. 56, pls. 4*).—This report deals with the results of pruning experiments, chiefly on apple trees, of which records have been kept for the last 12 years. The problems considered include the effect of branch pruning on growth and crop, summer pruning, cutting back transplanted, injured, or ailing trees, and the pruning of older trees. The results secured prior to 1905, based on the measurements of tree height, spread of the branches, and diameter of the stems, have been reported and noted (E. S. R., 17, p. 559).

In 1905 more than half the trees were dug up and weighed, and the tree-weights appear to more than substantiate the previous tree measurements in proving that the less a tree is pruned the larger and heavier it becomes. The details of the investigations are explained and discussed at length, and the results, together with the authors' conclusions, are summarized.

The main series of experiments were conducted chiefly on dwarf apple trees on paradise stock, with three varieties possessing very different habits of growth. At the end of 12 years those not pruned at all were 20 per cent heavier than those which were moderately pruned, whereas the hard-pruned trees were 16 per cent lighter. Since the difference in weight between the unpruned and moderately pruned trees is greatly in excess of the wood removed by pruning, it is concluded that pruning does not increase the actual size of the tree, but even results in less new wood being formed. When similar branches on the same tree were pruned to different extents it was found that the less the pruning the greater the number, length, and weight of new shoots formed and the increase in girth of the original branch.

The reduction in pruning appears more marked as regards the crop. With the dwarf apple trees, during the first 5 years, the crops from the unpruned trees were more than twice as great as from those moderately pruned, and more than three times as great as from those hard pruned. These differences were increased during the second period of 5 years, and at the end of the twelfth year the unpruned trees yielded nearly three times as much as the moderately pruned ones, while the hard-pruned trees had practically no crop at all. (Only 1 variety was in fruit for comparison during the twelfth year.)

Similar results were obtained in 1906 with trees of 53 and 80 varieties of the crab and paradise stocks, respectively. The trees were not allowed to overbear and it is claimed that the size of fruit obtained from trees pruned to different extents was approximately the same, hence the values of the crops were proportional to the weights. Confirmatory evidence of the antagonism of pruning to fruiting was obtained by counting the fruit-buds formed on similar branches of the same tree, which were cut back to different extents. All of the above results refer to healthy, vigorous, growing trees.

With the dwarf apple trees (15 years old) the authors find that hard pruning now results in an increase of the new wood formed, but that the crops are even more reduced by the pruning than in former years. This result is said to apply also to trees which have become stunted, as from root injury in transplanting.

Since hard pruning has been shown to be the correction for fruiting, it is concluded that freshly planted trees should be cut back hard to prevent stunting by precocious fruiting. With trees which were not cut back until the end of the first season the average size of the leaf was 24 per cent less and the new wood formed 45 per cent less than with similar trees cut back when planted. The ultimate result was found to be that trees not cut back until the end of the first year continued to form wood in subsequent years and the crop borne by them during the first 10 years was only one-third of that borne by those which were cut back when planted.

Experiments on apples, pears, and plums show that the date of cutting back a freshly planted tree is immaterial, providing it is done before growth begins. If delayed until after the growth is well started the season's growth is much reduced. This point was investigated with older, slightly stunted plum trees. The results were the same when the lopping was done during the dormant period. Lopping toward the end of May, or a few weeks after growth started, resulted in a less growth during the year, which was more than compensated by an additional growth during the succeeding season. Summer pruning, however, appears to be unfavorable for wood production.

While it appears to be established from these experiments that the crops are larger and the growth of the tree is greater in proportion as the pruning is reduced, the authors are of the opinion that another series of experiments might demonstrate that a certain amount of pruning may be good and even lead to better results than those obtained from their work, especially with certain varieties of apples which differ largely in their habits and require different treatment. The general conclusions reached are that prunings should be reduced to the lowest possible limits consistent with the formation of a tree of sufficient sturdiness to bear its crops with safety, which in most cases, would mean besides the cutting back after planting a gradually reduced pruning for the first four or five years. Pruning after this time should consist merely in the removal of interfering branches and unripened wood. With precocious varieties or very weak growers the pruning should be greater or continued longer. More pruning is required with standard than with dwarf trees, since with the standard it is desirable to produce a compact head before heavy crop production begins.

Atlas of fruits, A. S. GREBNITSKI ET AL. (*Atlas Plodov. St. Petersburg: Imp. Russ. Soc. Fruit Cult., 1903, vol. 1, pp. XXIII+158; 1904, vol. 2, pp. IV+159–308; 1905, vol. 3, pp IV+309–429; 1906, vol. 4, pp. 430–589, pls. 100*).—This work consists of colored illustrations, drawings, and pomological descriptions of over 100 of the best or most widely distributed commercial varieties of apples, pears, and drupaceous fruits in Russia.—P. FIREMAN.

Lists of fruits recommended for culture in Wisconsin (*Ann. Rpt. Wis. Hort. Soc., 37 (1907), pp. XX–XXII*).—Provisional lists, prepared by the trial orchard committee of the State horticultural society, are here given of all of the important orchard and bush fruits recommended for planting in Wisconsin. In the selection of these varieties particular attention has been paid to the hardiness of plant and fruit bud.

Cooperation in the marketing of apples, A. MCNEILL (*Canada Dept. Agr., Branch Dairy and Cold Storage Comr. Bul. 18, pp. 28*).—This bulletin contains a brief account of the origin and progress of apple growing in Canada and the varying conditions of the market for Canadian apples during the past 40 years, together with the history of cooperative associations in Canada, and a discussion of all the important features of the systems now in use. A list is also given of the cooperative associations of Ontario and British Columbia in successful operation during the season of 1906, together with the text of the constitution and by-laws of typical organizations.

Etherization of strawberries (*Gard. Chron., 3. ser., 41 (1907), No. 1063, p. 302*).—Brief mention is made of the work of M. Bultel[a] in forcing strawberries with ether, in which it was shown "that strawberries previously subjected to etherization not only flowered and fruited earlier but also bore a larger yield of fruit than others."

Judging from his experiments, M. Bultel is of the opinion that plants etherized for early fruit production give as satisfactory results as plants which are etherized for the production of early flowers.

The viticultural experiment station of Juazeiro, J. SILVEIRA (*Bol. Dir. Agr. Bahia, 8 (1906), Nos. 5, pp. 504–508; 6, pp. 586–592*).—The author gives a general account of the organization of the station, together with an outline of the work, which consists principally of variety tests of a large number of grapes, although attention is also paid to many other crops.

Report presented to the viticultural society of Lyon by the committee on hybrid direct-bearers for 1906, E. DURAND (*Vigne Amér., 31 (1907), No. 5, pp. 141–157*).—In this report some general considerations are given on the subject of grape hybridizing, together with a descriptive list of the hybrid direct-bearers considered by the committee to be of the most value for planting in France.

Recent observations on the hybrid direct-bearers in the Valley of the Rhone, A. DESMOULINS and V. VILLARD (*Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), Nos. 23, pp. 679–690; 24, pp. 719–724; 25, pp. 738–741*).—Observations have been made for the past 7 years on a large number of hybrid direct-bearers in vineyards of the Rhone Valley, and are here presented in tabular form, including the varieties, color of the fruit, period of maturity, vigor and degree of ripeness of the shoots, resistance to phylloxera, fungus diseases, and drought, together with brief notes on each variety.

Tabulated data are also given on studies made of the fruits and must from each variety, and the hybrids considered most valuable for the reconstitution of vineyards are discussed with regard to their hardiness, productiveness, resistance to phylloxera, mildew, etc., and the content of the wine made of the must in alcohol and sulphuric acid.

---

[a] Jour. Soc. Nat. Hort. France, 7 (1906), pp. 27, 191.

Fertilizer experiments with grapes at Graves [France], H. Verdié (*Rev. Vit., 27* (*1907*), *No. 704, pp. 657–660*).—This is a preliminary report on experiments conducted for the past 3 years to determine an economic fertilizer for the grape region of Graves. The ingredients used were in the following proportions: Dried blood 100 kg., sulphate of potash 200 kg., basic slag 800 kg., plaster 400 kg. The total cost of this fertilizer was computed as 137 francs ($26.44). Nine plats were used in the experiment, including the check plat, and this formula was varied on different plats by the omission of one or more elements. The soil in this region is sandy and noncalcareous.

A table is given showing the nature of the fertilizers used in each plat, the weight of 100 fruits, the percentage of skins, seeds, pulp, and juice, the weight of dry matter for 100 gm. of fresh berries, and the percentage of phosphoric acid and soluble potash. Another table shows the richness of the must of grapes from the various plats in grams of sugar and sulphuric acid per liter.

From these experiments the author concludes that growers are warranted in using chemical fertilizers in the manuring of vines for the production of high-grade wines. Although nitrogen increased the vigor of the vines, where the amount used was large the quality of the must appeared to be less rich than in plats where the nitrogen content was small. It is believed that potash has a decided influence on the quality of the fruit and must. To secure the best results the author recommends the use of the complete formula employed in the experiment, including the lime.

Cold storage of grape vines, E. H. Pratt (*Fruit Grower, 18* (*1907*), *No. 7, p. 3*).—A brief summary is given of the author's report at the meeting of the American Association of Nurserymen at Detroit as to an experiment conducted to test the value of cold storage for carrying nursery stock over from one season to the next.

In October, 1900, some grape vines were dug and placed in the ordinary storage house, where they remained all winter. On June 7, 1901, 3 boxes of these vines were placed in cold storage, 2 of which were kept at a temperature of 33° to 34° and the other at a temperature of 28°. In the latter part of September, after having been in cold storage 3 months and 19 days, the vines were replaced in the nursery storage house and carried over until the spring of 1902. A portion were then used in filling orders in March, 1902, but in order to test the value of the vines about 1,200 were retained by the firm and planted late in the following May. They grew well and were dug in the fall of 1902 and used in filling orders. The test appears to have been successful in every way. Further successful efforts in the cold storage of nursery stock have been noted (E. S. R., 17, p. 467).

Cold storage, G. H. McKay (*Proc. N. J. Hort. Soc., 32* (*1907*), *pp. 127–135*).—In this paper the author discusses conditions which should be observed in putting fruit in cold storage. In respect to the Kieffer pear it is stated that this fruit will stand a temperature of 32° F., and it is believed that much of the disrepute into which this pear has fallen is due to its having formerly been stored at a considerably higher temperature.

Considerable comparative data are also given with reference to the profits derived from the cold storage of fruit.

Cool storage and fruit fly (*Jour. Dept. Agr. West. Aust., 15* (*1907*), *No. 4, pp. 252, 253*).—A brief account, with tabular data, is given with regard to experiments conducted by T. Hooper on the destruction of the fruit fly maggot in fruit by means of cold storage. In previous experiments along this line, the manager of the refrigerating works of the Western Australian government had found that these maggots lived to resist temperatures of 44° to 38° F.; hence in the present experiments the wormy fruit tested was subjected to a temperature averaging from 33° to 35°. When taken out and examined, the eggs appeared fresh, but when subjected to ordinary temperature they failed to hatch out and shriveled up after a few days.

In the data obtained from this experiment 15 days was found to be the limit at which the maggot or eggs lived, although to insure perfect safety it is recommended that wormy fruit be submitted to cold storage at the above temperature for 3 weeks.

Formosa tea industry, J. H. Arnold (*Mo. Consular and Trade Rpts.* [*U. S.*], *1907, No. 321, pp. 149, 150*).—In this abstract of the author's report on the Formosa tea industry the exports of tea from Formosa during 1906 are given as 21,992,145 lbs., with an approximate value of $3,500,000, of which the United States took 17,159,310 lbs. as compared with 18,061,911 lbs. in 1905.

A tea expert has been endeavoring to show the Chinese growers the value of fertilizers in increasing the productivity of the crop without injuring the flavor of the tea. Utilization of the inferior leaves, whch were at one time a loss to the dealers, is recommended in the manufacture of pouchong and black teas. Pouchong tea is described as an oolong, scented with the flowers of jasmine, gardenia, etc., and has an extensive sale among the Chinese population in the Straits Settlements, the Philippines, Hawaii, and some parts of the United States. In 1906, 4,300,000 lbs. of pouchong tea was exported from Formosa, about one-half of which was produced on the island. An attempt is now being made to secure a market in Turkey and Russia for brick and black teas of Formosa manufacture, in the making of which it is hoped to utilize the tea dust which at present finds no market.

Pruning coffee trees, E. J. Nuñez (*Bol. Agr.* [*San Salvador*], 7 (*1907*), *No. 3, pp. 108–119, figs. 8*).—This article contains general considerations with regard to the principles and advantages of pruning, with a special discussion on the pruning of coffee trees.

Turkish hazelnut growing, M. A. Jewett (*Daily Consular and Trade Rpts.* [*U. S.*], *1907, No. 2908, pp. 11, 12*).—The author gives a brief description of hazelnut (filbert) production in the province of Trebizond, Asia Minor. It is estimated that 400,000 acres of land on the hillsides along the south shore of the Black Sea and extending 10 to 15 miles inland are devoted to filbert culture.

The young trees begin to bear at the end of the fourth or fifth year and are said to be at their best when 7 or 8 years old. The orchards are renewed at the end of 15 to 20 years' time. The nuts are harvested in July and August and dried and sorted to some extent before being brought to the market. There are 3 varieties grown—the round, pointed, and almond—of which the round nuts are most abundant and furnish the basis for prices. The "almond" filberts, while few, are of high quality and sell for 30 per cent more than the round. The pointed nuts are shipped in the shell and cost 10 per cent more than the round. The round nuts, which form the bulk of the crop, are usually shelled before being exported, since shelling effects a saving of about 50 per cent on the freight. The shells are used for fuel and a small quantity are shipped to Europe, where they are said to be used in adulterating spices.

The nuts are sometimes bleached by fumigation before they are exported. However, while this practice improves the color, it is said to injure the flavor and the keeping quality of the nuts and is not considered a beneficial practice. The total exports for 1906 were 80,000 cwt. of nuts in the shell and 85,000 cwt. shelled, of which 6,340 cwt., practically all shelled, valued at $63,834, were sent direct to the United States.

Hardy trees, shrubs, and vines suitable for planting in Oklahoma, O. M. MORRIS (*Oklahoma Sta. Bul. 73, pp. 6*).—This bulletin is a brief report on variety testing of trees and shrubs desirable for planting for timber, home adornment, and ornamentation of public parks. Descriptions are given of several trees recommended for general planting, together with notes on their economic value. Several lists are also given of hardy and tender trees and shrubs, useful native plants, hedge plants, and hardy vines and roses.

All the native shrubs worth planting, J. TIPLADY (*Ann. Rpt. Wis. Hort. Soc., 37 (1907), pp. 25–31, pls. 3*).—The author has compiled a list giving the common and botanical names of native shrubs best adapted to different locations and conditions in Wisconsin. The varieties are grouped together with reference to their size and adaptability to light and shade and to different degrees of soil moisture and fertility.

FORESTRY.

The use of the national forests (*U. S. Dept. Agr., Forest Serv., 1907, pp. 42, pls. 6*).—The object of this publication is to explain the true purpose and use of the national forests, "what they mean, what they are for, and how to use them." The forests are considered in regard to their value to the home seeker, prospector and miner, users of timber, range, and water, and to taxpayers and others. The methods of protecting the national forests by the Forest Service are discussed at length. In the appendix is given the text of the agricultural settlement act of June 11, 1906, together with the name and location, date of latest proclamation, and area of each national forest in the United States, Alaska, and Porto Rico. The grand total of 153 national forests comprises 147,948,685 acres.

Suggestions for forest planting in the Northeastern and Lake States (*U. S. Dept. Agr., Forest Serv. Circ. 100, pp. 15, fig. 1*).—Popular suggestions are given for the reafforestation of cut-over lands, worn-out agricultural lands, sand dunes, and barrens, together with the development of watershed protection and woodlots, including brief cultural notes and species recommended for planting. The suggestions contained herein are said to apply to the New England States, New York, New Jersey, Pennsylvania (except the western portion), Michigan, Wisconsin, and eastern Minnesota.

Suggestions for forest planting on the semiarid plains (*U. S. Dept. Agr., Forest Serv. Circ. 99, pp. 15*).—The suggestions contained in this circular are intended to apply to the western portions of Kansas, Nebraska, and Oklahoma, northwestern Texas, eastern Colorado, and eastern New Mexico, in which region the distribution of the rainfall is uneven and wide areas often suffer from prolonged drought. Some general considerations are given with regard to the advisability of tree planting for protective purposes, woodlots, and shade trees, together with suggestions as to methods of planting, cultivation, and care, and a list of trees recommended for planting in this area, including the Russian mulberry, Osage orange, green ash, black locust, honey locust, cottonwood, white elm, hackberry, hardy catalpa, boxelder, red cedar, and several species of pines.

Notes are also given with regard to the soil and climatic requirements, general characteristics, planting distances, and uses of the species mentioned.

Report of the superintendent of forestry, R. S. HOSMER (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 3 (1906), pp. 15–66, maps 4*).—This is a report of the work of the division of forestry for 1906, and embraces a discussion of forest reserves, forest extension, and miscellaneous forest work. The forest fire service and progress of forestry in the Territory are also considered, together with future plans and recommendations for the betterment of the work.

During the year 7 new forest reserves have been established, with an aggregate area of 126,825 acres, of which 62,425 acres have been actually set apart. The total number of forest reserves is now 12, with a combined area of 337,147 acres, of which 117,532 acres of unleased government land has been actually set apart.

Tabular data are given showing the area of leased, unleased, and private forest reserves in the islands of Kauai, Oahu, Maui, and Hawaii, together with maps showing the location of the 12 reserves established on these islands. A record is also given of the year's fires on the islands of Hawaii, Oahu, and Kauai.

The division of forestry has undertaken 3 kinds of rubber experiments. A systematic trial of Ceará rubber (*Manihot glaziovii*) has been made in various localities throughout the territory to ascertain definitely where this species will grow. The importation of seed or seedlings of other rubber-producing trees, together with their propagation and distribution, and systematic experiments in tapping rubber trees that have reached sufficient size for this purpose are also discussed.

Progress report of forest administration in the province of eastern Bengal and Assam for the year 1905–6, W. F. L. TOTTENHAM (*Rpt. Forest Admin. East. Bengal and Assam, 1905–6, pp. 62, map 1*).—This is the annual report in regard to the constitution, management, protection, sylviculture, exploitation, and financial results of the State forests of eastern Bengal and Assam for the fiscal year 1905–6. All the important phases of the work are presented in tabular form.

During the year 17,206 acres were added to the reserve forests, making the present total area 3,841,820 acres. The gross revenues amounted to 1,254,787 rupees ($602,297.76) and the expenditures to 675,863 rupees ($324,414.24).

There are 4 rubber plantations aggregating 2,928 acres scattered through the province, of which the most important is at Charduar, where 2,746 acres of *Ficus elastica* have been planted out. The net revenue of the year from the rubber plantations is given as 23,381 rupees ($11,222.88) and the commercial value of the undertaking appears to be established. The text is accompanied with a map, showing the forest areas in this province.

Notes on western [Australian] timbers, R. J. DALTON (*Agr. Gaz. N. S. Wales, 18 (1907), No. 2, pp. 143–145, fig. 1*).—A list is given of 16 kinds of timber found in western Australia, with notes on the uses of each.

The silva of Colorado. I. Trees of the pine family in Colorado, F. RAMALEY (*Univ. Colo. Studies, 4 (1907), No. 2, pp. 109–122, pl. 1, fig. 1*).—This is the first of a series of papers to be published with respect to the trees and shrubs of Colorado. The present paper deals with the pine family in that State, including the pines, spruces, and firs. General considerations are given with regard to the economic and other values of forests, together with a list of books dealing with the trees of Colorado, and keys with descriptions of the genera and species of the pine family in this State.

The uses of beech wood, H. ZOLIKOFFER (*Ann. Gembloux, 17 (1907), No. 5, pp. 264–279*).—An account is given of the mechanical and physical properties of beech wood, together with its use for railway ties, construction purposes, manufacture of carriages, furniture, etc., as well as its value for firewood and the manufacture of charcoal.

With reference to its use for railway ties as compared with oak the following illustration is given: A section of 808 oak ties on the railroad between Paris and Strassburg was examined at the end of about 12 years, during which period 128,000 trains had passed over them. Of the total number of ties 178, or 22 per cent, were found still intact, 275, or 34 per cent, were found passable, and 355, or 44 per cent, were found poor. On the line between Paris and Mülhouse a section of 224 beech ties was examined at the end of 14 years, during which time 109,000 trains had passed over them. Of the total number of ties 216 were good, 7 passable, and one alone was poor. Beech ties, however, are liable to split and should be bolted at the end.

Production of red cedar for pencil wood, L. L. WHITE (*U. S. Dept. Agr., Forest Serv. Circ. 102, pp. 19*).—The number of pencils manufactured in the United States each year is given as something like 315,000,000, for the production of which 300 tons, or 20,000 cu. ft. of wood are required daily, the greater part of which is red cedar.

In order to devise some method by which a future supply of cedar might be secured a study was made in Florida, Alabama, and Tennessee, where conditions are believed to be typical for cedar production. This circular contains the results of these studies, in which 2 species of red cedar are dealt with, the southern form (*Juniperus barbadensis*) and the northern from (*J. virginiana*). Among the phases considered are the commercial range, silvical characteristics, methods of reproduction, present logging methods, and future management. Two systems of management are discussed: "Woodlot management" to meet the needs of the small timberland owners, and "management of large holdings" for the use of pencil manufacturers in the position to grow their own timber.

The text is accompanied with a planting plan and several tables regarding the relation of diameter and crown width to age, the number of feet, total volume, and percentage of heartwood in the used length, and the clear length and total height at different diameters of forest-grown and open-grown cedar. Data are also given in regard to the cost, yields, and financial returns of red cedar plantations.

In order to have a constant supply of cedar on a 60-year rotation, it is estimated that about 225,000 acres should be fully stocked, and it is suggested that companies interested in this work purchase large holdings of suitable cedar land and manage the tract on a basis of a sustained annual yield.

The Douglas fir since its introduction into Europe (1828–1906), J. BOOTH (*Allg. Forst u. Jagd Ztg., 83 (1907), Jan., pp. 5–10; Feb., pp. 45–50; Mar., pp. 87–93; Apr., pp. 113–118*).—This is an historical account of the cultivation of the Douglas fir in Europe from its introduction in 1826 up to 1906.

Acacia macrocarpa, with respect to its production of tannin, G. BARBION (*Bul. Soc. Hort. Tunisie, 6 (1907), No. 25, pp. 79, 80*).—An account is given of the *Acacia macrocarpa* which has been cultivated for several years at the Tunis experimental garden. The trees when pruned are used for hedges and are said to yield a fusiform fruit from 6 to 10 cm. in length and weighing from 5 to 10 gm. when dried.

Upon analyzing these fruits, the director of the agricultural chemistry laboratory found the scales, which composed 52 per cent of the fruit, to contain 14 per cent of tannic acid, or practically the same amount as is obtained from rich tannic barks. The tannin has given satisfactory results when used on fresh hides and is to be further tested by commercial leather manufacturers.

The eucalyptus, A. ROYER (*Bul. Soc. Hort. Tunisie, 5 (1906), Nos. 22, pp. 207–216; 23, pp. 271–277; 6 (1907), 24, pp. 52–56; 25, pp. 95–99*).—This is a monograph on the eucalyptus tree, including a general consideration of the genus as a whole, botanical descriptions, history, discovery, and propagation, geographical distribution, classification of species according to soils and climate, important uses, and acclimatization in North Africa, together with its uses, properties, products, and defects, and a description of some of the better species growing in North Africa, including characteristics, soil, climate, cultivation, and uses.

The work concludes with directions for the culture of the eucalyptus, embracing sowing, nursery practices, shading, hybridizing, and selection. The author is of the opinion that the introduction and culture of the eucalyptus in Mediterranean Africa is one of the most remarkable and useful agricultural experiments of the past century.

Tapping Funtumia rubber, H. H. Bell (*Agr. News [Barbados], 6 (1907), No. 127, p. 77*).—The writer gives an account of the tapping of *Funtumia elastica*," or "Lagos silk rubber" in the Budonga forest in Uganda, Africa, together with a description of the treatment of the latex. The trees are tapped every 3 months on different sides of the trunk. The average yield of the latex at each tapping is given as about 1 qt. per tree, with an annual average yield of 1 lb. of pure rubber. The process of coagulation is described. It is stated that a considerable quantity of Funtumia has been planted in the West Indies in the last 2 or 3 years. Rubber from this tree is now selling in London at 5s. 6d. per pound, a price almost equaling that obtained for the best Para rubber.

The valuation of rubber, M. Calmon (*Bol. Dir. Agr. Bahia, 9 (1907), Nos. 1, pp. 1–32; 2, pp. 117–154*).—This is a report of the commissioner of agriculture and industry on the production and commercial importance of rubber, including an account of the development of the industry in all of the important rubber-producing countries and a large number of statistics taken from various sources with respect to the exploitation, the imports and exports of crude rubber, and the commerce in articles made of rubber in the various rubber-consuming countries.

The open-tank method for the treatment of timber, C. G. Crawford (*U. S. Dept. Agr., Forest Serv. Circ. 101, pp. 15, figs. 4*).—This method of treating timber was originated by the Forest Service as a result of experiments conducted to obtain some cheap and simple process of wood preservation adapted for timber in common use for which the pressure methods are too expensive. In this circular consideration is given to the history, description, theory, and methods employed in the open-tank process, with its application and limitations. Descriptions follow of the necessary apparatus, together with diagrams of experimental tanks for treating fence posts, telephone poles, and mine timbers, as well as a diagram of a small commercial plant.

The open-tank method is based upon the use of an open tank, capable of withstanding heat, and either equipped with steam coils or so arranged that a fire can be placed underneath. Extensive experiments by the Forest Service with fence posts, telephone poles, and mine timbers have given satisfactory results, and it is believed that any of the preservatives in general use can be applied by the open-tank method for the treatment of fence posts, telephone poles, mine props, small dimension timber, cross-ties, piling, and similar timbers, provided that the temperatures are properly controlled.

DISEASES OF PLANTS.

Report of the biological division, F. L. Stevens (*North Carolina Sta. Rpt. 1905, pp. 20–29*).—A summary is given of the investigations carried on by the biologist of the station during the period covered by the report, the principal observations being on the disease of tobacco known as Granville wilt. Among the miscellaneous notes, accounts are given of the asparagus rust, which has become quite destructive in portions of North Carolina and for which sulphur applications are recommended; the powdery mildew of the rose, to prevent which spraying with potassium sulphid is advised; a disease of sweet potatoes, due to *Fusarium* sp., which results in a wilt of the plants; and a disease of apples, to which the name apple scurf is given. This apple disease is of fungus origin, although the species has not been determined. It affects the bark, causing the appearance well described by the name given, and the characteristic malformations have been repeatedly formed through inoculation experiments.

The tobacco wilt is said to be the most important of the diseases under investigation, and for its control the author has conducted experiments in soil treatment as well as in the breeding of resistant races. A large number of chemical substances were used in attempts to destroy the fungus in the soil, without results that would be considered satisfactory in ordinary use. During the progress of these investigations the susceptibility of a considerable number of plants to this fungus was tested, and it was found that Irish potatoes and tomatoes were subject to a disease which in all appearances was like the tobacco wilt. Specimens of eggplant and peppers were similarly affected, but the identity of the diseases on these plants with tobacco wilt is not fully established. Experiments with the electric current for sterilizing the soil were undertaken without beneficial results. The most promising means of overcoming the Granville tobacco wilt is believed to be in the breeding and selection of resistant varieties or races. A considerable number of these have been experimented with and marked differences in susceptibility to disease are noted.

Notes on the watermelon wilt, and a brief account of experiments in breeding by selection and hybridization for resistant varieties are given. These latter experiments were in cooperation with the Bureau of Plant Industry of this Department.

The root-rot fungus, M. C. Cooke (*Gard. Chron., 3. ser., 41 (1907), No. 1067, p. 361, fig. 1*).—Attention is directed to a disease due to *Thielavia basicola*, which attacks indiscriminately a great variety of cultivated plants, the account being largely drawn from the report of the Connecticut State Station for 1906 (E. S. R., 18, p. 1138). According to the author this fungus has been reported on peas, horse-radish, cyclamen, lupines, tobacco, sainfoin, senecio, violets, aralia, and nemophila. It is shown that the fungus, which is usually saprophytic, becomes under favorable conditions an aggressive parasite.

Take-all and its control, G. H. Robinson (*Jour. Dept. Agr. Victoria, 5 (1907), No. 4, pp. 253-256*).—A description is given of the disease known in Australia as take-all, which is due to the fungus *Ophiobolus graminis*. For the control of this disease rotation of crops, burning over of badly affected stubble, early fallowing, and the substitution of crops not liable to disease are recommended.

Diseases and injuries to beets in 1906, R. Schander (*Bl. Zuckerrübenbau, 14 (1907), No. 8, pp. 113–119*).—The summer of 1906 is said to have been especially favorable to plant diseases in West Prussia, and brief accounts are given of the more important fungi and insects observed as attacking beets. Among the more important ones described are the beet-root rot (*Phoma betæ*), a dry rot, and a rot due to *Rhizoctonia violacea*, which were especially destructive. Beet scab and the leaf spot caused by *Uromyces betæ* were not very prevalent and the bacterial black rot was not observed. Among the more troublesome animal pests were nematodes, wireworms, field mice, etc. Suggestions are given for the control of all the serious pests.

The zonal beet scab, A. Stift (*Bl. Zuckerrübenbau, 14 (1907), No. 10, pp. 151–153*).—A description is given of a form of beet scab that from its habit of girdling the root is called zonal scab. This disease has been attributed by different authors to various causes, one claiming that it is caused by attacks of minute worms, species of Enchytræidæ, followed by *Oospora* sp. (E. S. R., 16,

p. 886), and that the sugar content of the beet is diminished in direct proportion to the severity of the attack of the disease.

After investigating this disease for several years the author failed to find any connection between the dry weight, sugar content, etc., of beets and the presence of the disease. He also failed to discover that the worms had anything to do with it. In regard to the fungus he reserves his opinion until further study.

The selection of sugar cane cuttings in combating the red rot, E. J. BUTLER (*Agr. Jour. India, 2 (1907), No. 2, pp. 193–201, pls. 3*).—An experiment in selecting seed cane for the prevention of the red rot of sugar cane caused by the fungus *Colletotrichum falcatum* is described.

An especially susceptible variety of cane was selected to test the effect of planting the red-spotted and spot-free cuttings. The effect of planting diseased cuttings was so marked that the author suggests the inspection of all cuttings, and, as the fungus often does not run through the whole cane, tops instead of butt sections should be selected for planting. Experiments show that the fungus does not persist long in the soil, and with the planting of more resistant varieties and the examination of cuttings much of the present loss would be avoided.

The smuts of cereals; their distribution and prevention, O. BREFELD, O. APPEL, ET AL. (*Jahrb. Deut. Landw. Gesell., 22 (1907), No. 1, pp. 75–91*).—After a review, showing the status of information regarding cereal smuts, an account is given of various methods for their control. These include hot water, formalin, copper sulphate, and other treatments of the seed, and the efficiency of the different methods in preventing smut as well as the effect of the different treatments on the germination of the seed are discussed.

Notes on Ustilago esculenta, S. HORI (*Ann. Mycol., 5 (1907), No. 2, pp. 150–154, pls. 2*).—A description is given of this interesting smut which occurs on species of Zizania, the smutted grains of which are said to be considered quite a delicacy in Formosa. In describing the fungus comparisons are drawn between specimens obtained in Formosa and in Tokio, the Formosa material being much larger in every way. On account of the differences, the author has given an amended description of the fungus and describes its germination, distribution, etc. The smutted plants are said to retain their greenish color for a long time in the autumn and as a consequence are readily distinguished from the normal plants. The smutted shoots assume a long spindle shape and remain within the leaf sheaths for a long time. The leaf shoots of the Formosa specimens attain a length of 10 to 20 cm. or 2 to 4 times larger than those hitherto reported.

Some diseases of cereals caused by Sclerospora graminicola, E. J. BUTLER (*Mem. Dept. Agr. India, Bot. Ser., 2 (1907), No. 1, pp. 24, pls. 5*).—A diseased condition of pearl millet is described in which the heads are transformed into curious leafy proliferations due to the presence of the above fungus. Other portions of the plant are subject to attack, the mycelium of the fungus having been found in the stems, leaves, and various parts of the flower spike. Technical descriptions are given of the various phases of the fungus.

The same organism is said to attack *Andropogon sorghum*, causing a condition known as shredding of the leaves. The fungus occurs in the leaves of this plant, where it destroys the parenchyma, resulting in the torn condition.

In addition to the above, *S. graminicola* occurs on Italian millet and teosinte. Upon the latter host plant only the sporangial stage has been observed.

The characters observed for the fungi on all these hosts agree with those given for Sclerospora, 3 species of which are recognized, and the author believes that probably a fourth should be included, *Peronospora maydis*, thus including all the Peronosporaceæ known to occur on grasses.

Note on the infection and histology of two wheats immune to the attacks of yellow rust, DOROTHEA C. E. MARRYAT (*Jour. Agr. Sci., 2 (1907), No. 2, pp. 129–138, pl. 1*).—Infection and histological experiments are reported in which a variety of wheat (American Club) and Einkorn, a half-wild form of *Triticum monococcum vulgare*, were studied to determine the infection by the yellow rust (*Puccinia glumarum*). For purposes of comparison a very susceptible variety (Michigan Bronze) was used. Seedlings of these three varieties of wheat were grown and when the young plants were well developed all were infected by placing spores on the leaves. These were observed from time to time and the infected material subjected to histological examination. In the normal development of the fungus the germ tubes pass through the stomata into the tissues beneath where haustoria are developed with considerable rapidity. Ordinarily numerous nuclei are present in the hyphæ, large numbers of haustoria are developed, and a healthy condition of the host cells is maintained about the developing fungus. After about 10 days the small hyphæ begin to mass themselves beneath the epidermis and later pustules develop.

In a case of the very resistant Einkorn, the germ tubes enter as usual through the stomata, but almost in the beginning the contents of the hyphæ look watery and show very few nuclei. They appear to be too feeble to send out any haustoria, the host cells in the vicinity of the fungus are shrunken, and in later stages the leaf tissue apppears a dead, shriveled mass.

It appears that in this immune wheat, although the fungus makes its entry and produces abundant hyphæ, yet sooner or later it is starved to death by the breaking down and death of the host tissue in its vicinity, and as a consequence the fungus is unable to make further progress. The host plant, on the other hand, having checked the parasite, continues to flourish except for the small dead areas mentioned above. With the third species of wheat, which appears to be intermediate between the susceptible Michigan Bronze and the resistant Einkorn, the entry takes place through the stomata. The hyphæ appear for a time perfectly healthy and some develop normal haustoria, but before long the progress of the parasite is checked and only in occasional cases are spores produced. In the case of immune varieties, it appears that while the fungus succeeds in making good its entry and producing hyphæ, further progress is completely checked by the breaking down and death of the host tissue accompanied by the starvation and death of the parasite, as in the Einkorn, or else a more protracted struggle takes place, as in the American Club. In the latter case the development proceeds to a farther point, but is retarded as compared with a normal case such as described from the Michigan Bronze.

The reason for this immunity is unknown, but for the present the author suggests that it is probably due to the production of certain toxins and antitoxins by host or parasite, or both, which are mutually destructive.

A leaf-curl disease of cassava, A. ZIMMERMANN (*Pflanzer, 2 (1906), No. 10, p. 145; abs. in Centbl. Bakt.* [*etc.*], *2. Abt., 18 (1907), No. 10–12, pp. 366, 367*).—A description is given of a disease of cassava in which the leaves become curled and variously distorted. So far a large number of causes have been assigned to this disease, but after investigating the subject the author reports that he is unable to find any fungus or animal parasite in the affected leaves, and he believes that it is very likely due to causes similar to those producing the mosaic disease of tobacco, the infectious chlorosis of mallows, etc. Some varieties of cassava seem to be especially subject to it, and in making plantings those that are known to be liable to it should be rejected.

The American gooseberry mildew (*Jour. Bd. Agr.* [*London*], *14* (*1907*), *No. 2, pp. 104–106, pl. 1, figs. 2*).—An illustrative description is given of the American gooseberry mildew (*Sphærotheca Mors-uvæ*), which appears to be quite destructive to gooseberries and seems to be spreading in different parts of Europe. An account is given of this disease so that growers may be able to recognize it upon their bushes and aid in repressing its distribution.

Notes on some diseases of the pineapple, N. A. Cobb (*Hawaii. Forester and Agr.*, *4* (*1907*), *No. 5, pp. 123–144, figs. 9*).—The author gives an account of some of the more troublesome diseases of the pineapple in Hawaii and calls attention to the occurrence of *Thielaviopsis ethaceticus* on the pineapple.

This fungus, which has been previously described by the author (E. S. R., 18, p. 843), causes the well-known pineapple disease of sugar cane as well as the most common rot of pineapples in Hawaii. It is characterized on the fruit by a blackening which usually begins at the cut end of the stem and spreads upward through the core, ultimately involving the entire fruit. This discoloration, which is dark at first, becomes sooty black when fully developed. The fungus is described at considerable length, and its dissemination on the pineapple seems to be associated with various insects, principally flies. The author suggests that where tops are used for planting, diseased specimens should be eliminated as far as possible. Additional precautions of dipping in fungicides will probably be found advantageous. Experiments with the treatment of sugar cane for the prevention of this disease have proved very efficient, and the use of Bordeaux mixture or tar upon the pineapple cuttings is recommended as a preventive treatment.

Diseases of coffee, G. Delacroix (*Agr. Prat. Pays Chauds*, *7* (*1907*), *Nos. 50, pp. 384–399; 52, pp. 26–41; 53, pp. 152–165, pls. 3*).—A description is given of some of the better known diseases of coffee, the author grouping them according to whether they are due to nonparasitic or parasitic causes. Among the leaf diseases of coffee the principal one described is that caused by *Hemileia vastatrix*.

Root diseases of tea, T. Petch (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, *28* (*1907*), *No. 5, pp. 292–296, pl. 1*).—The author describes some root diseases of the tea plant which have previously been referred to a fungus, *Rosellinia radiciperda*, but which are now believed to be due to different fungi. One form of the disease which is said to occur on tea plants growing at an elevation of 4,000 ft. or more is caused by the fungus *Porias hypolateritia*. This fungus also attacks the roots of Hevea rubber and seems to spread to the tea roots from stumps of various forest trees. In the lower districts a root disease of tea appears in which the roots show black nodules from which arise an underground mycelium which spreads between the wood and the bark in white or yellowish fan-shaped patches. The fungus appears to be an undescribed species of Ustilina, a brief description of which is given. For preventing these diseases the author recommends the digging out and burning of dead bushes and the burying or burning of all tea prunings.

The downy mildew of grapes and its control, J. Capus (*Rev. Vit.*, *27* (*1907*), *Nos. 705, pp. 677–680; 706, pp. 705–708*).—The author has made a study of the downy mildew of grapes and its control, the investigations covering a period of 5 years.

The appearance of the mildew on the vines was found to be closely associated with periods of high temperature, and the period of incubation of the various invasions varied from 7 to 28 days, depending upon the prevailing temperature conditions. As a rule the mildew was found to be most severe in its attacks on the older leaves, the young leaves being nearly free from the invasion of the

fungus. On this account it was found to be especially necessary to protect the foliage with fungicides during the months of August and September.

Experiments were conducted with different strengths of copper sulphate solutions and Bordeaux mixture, and it was found that while weak solutions were efficient in protecting the leaves for a time against the invasion of the fungus, the period of protection was much shorter than where stronger solutions were employed. In a comparison of the efficiency of simple solutions of copper sulphate a 1 per cent solution upon the leaves remained protective for 28 days, while a 2 per cent solution remained efficient for 48 days. A solution containing about ¼ of 1 per cent copper sulphate was effective for only 7 or 8 days. In practice it was found that spraying thoroughly with a 2 per cent solution late in July will ordinarily protect vines against the downy mildew throughout the remainder of the season.

The resistance of table grapes to downy mildew, R. SALOMON (*Rev. Vit., 27 (1907), Nos. 701, pp. 576–578; 703, pp. 630–633*).—A report is given of investigations to determine the relative susceptibility of varieties of table grapes to mildew. In all 180 varieties, represented by over 800 specimens, were observed during the years 1902, 1903, 1904, and 1905. The grapevines were all in the same field, were sprayed 3 times with Bordeaux mixture, and were subjected to similar conditions throughout. In reporting upon these different varieties the author adopted a scale of resistance, and while some differences were noted due to slight attacks of the fungus on some of the species, yet in general the relative resistance remained the same. The relative resistance of the different varieties is shown in tabular form

A new treatment for downy mildew, E. CHUARD (*Chron. Agr. Vaud, 20 (1907), No. 9, pp. 181–188*).—In reporting upon experiments for the control of the downy mildew of grapes, the author gives an account of the use of a new fungicide which he claims has proved very efficient. This fungicide is made by dissolving 200 gm. of copper oxychlorid in a hectoliter of water, with which the vines were given 5 applications. The copper oxychlorid is said to be an intermediate product in the manufacture of copper sulphate and consists of a combination of chlorate and oxid of copper. This fungicide does not appear to injure the foliage even when used in very strong solutions. It is sufficiently noticeable when sprayed upon foliage and appears to be exceedingly adhesive.

A disease of larch trees in Jura, L. MANGIN and P. HARIOT (*Bul. Trimest. Soc. Mycol. France, 23 (1907), No. 1, pp. 53–68, figs. 9*).—A description is given of a disease of larch trees which is characterized by the orange-red color assumed by the leaves of diseased trees. These, standing out against the uniform green color of the other trees, make them very conspicuous objects. This disease has been attributed to the fungus *Hypoderma nervisequum*, but the authors have found a number of species of fungi attacking the foliage, the more important of which are noted in a preliminary account (E. S. R., 18, p. 650). In addition to these fungi a number of others seem to occur quite uniformly upon the leaves, so that the authors are unable to decide what particular organisms are the cause of the disease. It is believed, however, that *Rhizosphæra abietis* is one of the most prominent in causing the trouble.

A disease of maple trees, F. VON HÖHNEL (*Österr. Bot. Ztschr., 57 (1907), No. 5, pp. 177–181*).—A disease of the maple, *Acer campestre*, is described which is attributed to the fungus *Polyporus radiatus*. The author points out resemblances between this fungus and a number of other allied species and gives a technical description of it.

The leaf blotch of maples (*Jour. Bd. Agr. [London], 14 (1907), No. 2, pp. 106, 107, fig. 1*).—Descriptive accounts are given of two forms of leaf blotch occurring on different species of maple, the fungi causing them being *Rhytisma acerinum* and *R. punctatum*. As a means of preventing the spread of this disease it is recommended that the dead leaves lying upon the ground be collected and burned, as the fungus passes the winter upon them.

A pine disease (*Jour. Bd. Agr.* [*London*], *14* (*1907*), *No. 3, pp. 164–166*).—It is stated that diseased shoots of pine have been sent to Kew from time to time, but until March, 1906, no definite statement could be given as to the primary cause of the disease by reason of the failure to secure the development of the fungus.

The disease is confined to the terminal shoots and may be recognized by the yellowing and subsequent shedding of the leaves, followed by the death of the shoots, which die back for a distance of 6 to 10 in. These dead shoots are persistent and furnish centers for infection of other shoots. An investigation of the host plant showed that the injury was due to the fungus *Diplodia pinea*, a wound parasite.

Inoculation experiments demonstrated that within 2 months after infection the leaves become yellow and at the expiration of 4 months the leaves have fallen and the shoot is dead. These experiments were carried on with 3-year-old plants of white pine, Scotch pine, spruce, silver fir, and larch, by placing the spores on the young shoots, but positive results were obtained only in the case of the 2 species of pine.

Although the fungus is quite destructive, its entry to the host was found to depend on the presence of some previous wound and it is probably associated with some insect, but as yet this point has not been settled.

In the case of nursery stock and young trees the author recommends the removal of all dead shoots to prevent the further spread of the fungus.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Outlines of zoology for foresters, A. JACOBI (*Grundriss der Zoologie für Forstleute. Tübingen: H. Laupp'schen, 1906, pp. XI+263, figs. 441*).—The present volume is intended as a supplement to T. Lorey's Handbook of Forestry, as it is believed that in the latter volume the subject of forest zoology was not considered at sufficient length for the purposes of the practical forester. In this supplementary volume, therefore, a general account is given of gross and microscopic anatomy of animals. The greater part of the volume is occupied with a systematic account of the various groups of animals which are of economic importance to the forester.

Destruction of deer by the northern timber wolf, V. BAILEY (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 58, pp. 2*).—In northern Michigan, Wisconsin, and Minnesota it is reported that deer are killed in considerable numbers in the deep snow of winter by timber wolves. In this section of the country the breeding season for the wolves appears to be later than in the Rocky Mountains. Wolves may be destroyed by locating the dens and killing the puppies, or by the use of traps.

Game protection in Florida, R. W. WILLIAMS, Jr. (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 59, pp. 11, fig. 1*).—The essential facts in the history of legislation regarding game protection in Florida are presented, together with a list of the game laws of that State. The author also takes occasion to discuss the present status of game protection in Florida and the functions of game commissioners.

Notes on the Sabi game reserve, J. S. HAMILTON (*Transvaal Agr. Jour., 5* (*1907*), *No. 19, pp. 603–617, pl. 1*).—The Sabi game reserve was established in the Transvaal in 1898 and has been found to serve excellently well the purposes for which it was set aside. The animals which are protected in this reserve are not found in the United States, but the author calls attention to the fact that the conditions in South Africa and the United States are essentially the same in that a number of the most interesting and most valuable native animals are apparently doomed to extinction unless given the protection of a reserve.

Methods of destroying rats, D. E. Lantz (*U. S. Dept. Agr., Farmers' Bul. 297, pp. 8, fig. 1*).—The common brown rat is considered the most injurious mammal in the country. It may be combated by poisoning with barium carbonate, strychnin, arsenic, or phosphorus; trapping, especially with some form of guillotine trap; the use of ferrets and dogs; fumigation with carbon bisulphid in burrows; and by the general adoption of rat-proof construction of buildings, which may be accomplished by the use of cement.

Means of destroying rats, mice, and snails, H. Raebiger (*Jahrb. Deut. Landw. Gesell., 22 (1907), No. 1, pp. 104–130*).—The common methods for the destruction of rats and mice include the use of traps, poisons, and bacterial cultures. In the author's experience, traps and poisons have given less satisfactory results than bacterial virus, particularly a form of virus which has been extensively used by the German Agricultural Society. In some instances, this does not cause an infection, but the author believes that rats and mice vary greatly in their resisting power.

In combating snails and slugs, the author recommends sprinkling dry powdered lime on plants so that snails will come in contact with it. The lime dust sets up a fatal irritation on the integument of snails.

The occurrence of field mice and means of combating them, N. Hiltner (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 5 (1907), No. 5, pp. 50, 51*).—Brief notes are given on the injuries which may be produced by field mice and on the distribution of virus for causing infection among these pests.

The protection of our native birds, T. H. Montgomery, Jr. (*Bul. Univ. Texas, Sci. Ser. No. 8, pp. 30*).—The author presents a series of arguments in favor of bird protection and gives data regarding the destruction of birds for food and millinery purposes and on the means of bird protection.

Bird protection, H. von Berlepsch (*Jahrb. Deut. Landw. Gesell., 22 (1907), No. 1, pp. 130–157, figs. 20*).—Descriptions are given of a large number of devices for feeding birds and for use in nesting.

Injurious birds, Knotek (*Naturw. Ztschr. Land u. Forstw., 5 (1907), No. 6, pp. 273–280, figs. 3*).—Particular attention was directed to the attacks of magpies, jays, and various species of crows on corn. Illustrations are also given of the injury to the foliage of coniferous trees from various wild species of grouse.

Index-catalogue of medical and veterinary zoology, C. W. Stiles and A. Hassall (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 39, pt. 18, pp. 1305–1398*).—This part of the bulletin contains the names of authors arranged alphabetically from Martius to Mitrofanow.

The use of glass vessels in the study of the relations between insects and flowers, F. Plateau (*Acad. Roy. Belg., Bul. Cl. Sci., 1906, No. 12, pp. 741–775, figs. 2*).—In the author's experience it appears that the color of flowers is not as important a source of attraction to insects as has usually been assumed. Other factors are observed to exercise more influence in determining the flight of insects in visiting flowers.

Fourth annual report of the State entomologist of Montana, R. A. Cooley (*Montana Sta. Bul. 64, pp. 33–45*).—Brief notes are given on the cutworms in winter wheat fields, the sugar-beet webworm, codling moth, cabbage plutella, currant spanworm, rose slug, spotted blister beetle, grasshoppers, cabbage aphis, etc.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Div. Zool., 4 (1907), Nos. 11, pp. 385–414; 12, pp. 415–450, pls. 6*).—Notes are given on methods of destroying the cabbage root-worm and San José scale. Remedies are also suggested for use in controlling codling moth, cutworm, tent caterpillars, etc.

On some injurious insects in 1906, R. S. MACDOUGALL (*Trans. Highland and Agr. Soc. Scot., 5. ser., 19 (1907), pp. 173–188*).—*Lampronia rubiella* on raspberries may be best combated by cutting off and burning infested shoots. Raspberry weevils are partly controlled by the cautious use of boiling water about the canes. Protection may be afforded strawberries against the attack of ground beetles by the use of baited traps at night.

In insecticide work against the currant gall mite the best results were obtained from dusting infested plants with a mixture of lime and sulphur. The author found that grain weevils would remain alive for from 8 to 14 months in small tubes partly filled with wheat.

The natural history of Tapinostola musculosa, S. MOKRZECKI (*Ztschr. Wiss. Insektenbiol., 3 (1907), Nos. 2, pp. 50–53; 3, pp. 87–92, figs. 6*).—The caterpillar of this moth attacks the stems of wheat, barley, rye, and other cereals, causing at times serious losses. The insect passes the winter in the egg stage, and since the eggs are deposited on stubble and volunteer grass and other plants in grain fields, obvious remedies are to burn the stubble after harvest or to plow the ground deeply.

A fight with climbing cutworms (Leucania unipuncta), W. W. FROGGATT (*Agr. Gaz. N. S. Wales, 18 (1907), No. 3, pp. 265–268*).—A description is given of a serious outbreak of army worms in which good success was had from the use of poisoned bait composed of bran and Paris green.

The periodical cicada in 1907, C. L. MARLATT (*U. S. Dept. Agr., Bur. Ent. Circ. 89, pp. 4, figs. 3*).—This circular is published for the purpose of eliciting information concerning the brood of periodical cicada which appeared in May and June of this year throughout the southern States, east of Texas, except Florida, and northward as far as Iowa and Illinois.

The use of cloth barriers and hopperdozers in combating locusts, E. DE BANÓ (*Com. Par. Agr. [Mexico], Circ. 56, pp. 9, pls. 8*).—A description of methods adopted in combating the locust plague in Hungary. In this campaign barriers were constructed of cloth and the locusts were gradually driven into partly enclosed spaces in which they were easily captured. An account is also given of various forms of hopperdozers used for the same purpose.

Some insects injurious to truck crops. The asparagus miner. Notes on the asparagus beetles, F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Bul. 66, pt. 1, pp. 10, figs. 2*).—*Agromyza simplex* has been known as causing injury to asparagus since 1896. It is distributed from New England to Tennessee. Notes are given on its habits and life history. The larvæ live under the epidermis of the stems. In controlling this insect it is recommended that a few volunteer asparagus plants be allowed to grow as a trap crop in the spring and that these be later destroyed. It would also be well to pull up and destroy infested plants in old asparagus beds in order to accomplish the destruction of the second brood of flies.

Some insects injurious to truck crops. The water-cress sowbug. The water-cress leaf-beetle, F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Bul. 66, pt. 2, pp. 9–20, figs. 3*).—An aquatic sowbug, belonging to the species *Mancasellus brachyurus*, is reported as causing great injury to water-cress in Virginia, West Virginia, and Pennsylvania. According to some of the correspondents of the Bureau it is practically impossible to control this pest by means of insecticides alone. The best results are obtained by constructing the beds in which the water-cress is grown with a trough running through the central lowest point at such a grade that the water can be drained off at will. The sowbugs follow the receding water, and when they are all in the trough they may be destroyed by the liberal use of sulphate of copper. It is possible that carp and other fish may also be of service in destroying this pest.

The water-cress leaf beetle (*Phædon æruginosa*) was reported as injuring water-cress in Pennsylvania in 1903. The beetle is described in its various stages and notes are given on its life history. Some benefit is derived by the application of Paris green to infested water-cress, but this should not be done later than 1 week before the cress is picked. Better results are reported from growing water-cress in running water which carries the beetles away.

Biological notes on the Colorado potato beetle, with technical description of its stages, A. A. GIRAULT and A. H. ROSENFELD (*Psyche, 14 (1907), No. 3, pp. 45–57*).—Opportunity was had to study the various stages in the life history of the Colorado potato beetle at Myrtle, Georgia. The insect is described in all its stages and notes are given on the duration of these stages and the external appearance of the insect as observed in the Southern States.

The Colorado potato beetle, F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Circ. 87, pp. 15, figs. 6*).—In the gradual spread of this insect its attacks upon potatoes become so severe in localities where it is little known that information regarding its life history and methods of combating it seems to be required. The beetle is believed to have originated in Colorado and after having traveled to the Atlantic Coast has been spreading northward and southward, although climatic conditions are not always favorable. Its spread eastward was more rapid than its present extension southward. It has not been able to cross the Rocky Mountains.

Notes are given on its habits, life history, food plants, and natural enemies. The methods of control suggested by the author include jarring, brushing, fall plowing, the eradication of wild weeds upon which the beetles feed, and the use of arsenicals, including Paris green applied dry or in water or Bordeaux mixture, arsenate of lead, and other arsenicals. Preference is given to arsenate of lead.

Combating grapevine flea beetle, FONZES-DIACON (*Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), No. 20, pp. 582–585*).—A formula has been proposed for the preparation of an insecticide to destroy grapevine flea beetles, which calls for 500 gm. anhydrous arsenate of soda and 225 gm. of lime per 100 liters of water. The author calls attention to the fact that the insecticide resulting from the chemical action of these constituents varies considerably in composition and that some arsenate of soda may remain unchanged, although it has been claimed that the effective element of the insecticide was the arsenate of lime.

Insects affecting fruit trees, C. J. S. BETHUNE (*Ontario Dept. Agr. Bul. 158, pp. 36, figs. 4*).—A popular presentation is made of the important facts relating to insect pests of the apple, pear, plum, cherry, peach, and grape. Formulas are also given for the preparation of lime-sulphur wash, kerosene emulsion, Paris green and Bordeaux mixture, and other insecticides.

Xyleborus xylographus as an orchard pest, O. E. BREMNER (*Canad. Ent., 39 (1907), No. 6, pp. 195, 196*).—This species of ambrosia beetle is commonly reported as attacking only those trees which are already dead or dying as a result of some disease or insect injury. The author observed primary attacks of the pest, however, upon healthy peach and plum trees. Galleries containing the insect in all stages of development were found from early spring until fall. Apparently the beetles enter the tree from the north and east sides and ordinarily not more than 6 ft. from the ground.

Kerosene remedy and the fruit fly, G. COMPERE (*Jour. Dept. Agr. West. Aust., 15 (1907), No. 4, pp. 244, 245, pl. 1*).—A self-feeding kerosene trap has been devised which seems to have been quite effective in catching the fruit fly. According to the author's experience the odor of kerosene attracts this insect.

Combating codling moth with arsenicals, J. BARSACQ (*Jardin, 21 (1907), No. 484, pp. 124-126, figs. 2*).—Mixtures of Paris green, lime, and flour in water were used in spraying to combat the codling moth. It is considered that the first application should be made while the calyx is still open and that this should be immediately repeated if followed by a rain storm. In these experiments control trees showed 14.45 per cent of infested fruit, while trees sprayed with the Paris green bore only 7.46 per cent of wormy apples. Arsenate of lead in Bordeaux mixture gave still better results, the percentage of infestation being 2.15.

The terrapin scale, J. G. SANDERS (*U. S. Dept. Agr., Bur. Ent. Circ. 88, pp. 4, figs. 3*).—A detailed description is given of *Eulecanium nigrofasciatum* with notes on its food plants and natural enemies. This pest affects chiefly peach trees. It can not be satisfactorily controlled with the lime-sulphur wash, but kerosene emulsion gives good results.

Notes on Chermes, BÖRNER (*Mitt. K. Biol. Anst. Land u. Forstw., 2 (1907), No. 4, pp. 54-60, figs. 8*).—The various stages in the life cycle of *Chermes strobilobius* and *C. abietis* are presented.

The history of certain insect pests of the olive, A. BERLESE (*Redia, 4 (1907), No. 1, pp. 1-180, pls. 3, figs. 60*).—A detailed report is made on the work of the Royal Agricultural Entomological Station at Florence on olive insects, particularly olive fly, *Lasioptera berlesiana, Lecanium oleæ, Philippia oleæ*, etc. The author calls attention to the great variation in the numbers of these insect pests which appear from year to year. This variation appears to be due largely to the relative prevalence of their natural enemies, particularly parasites and predaceous insects. In combating the olive fly it is stated that excellent results have been obtained for a number of years from the use of a mixture containing 65 parts of molasses, 31 parts of honey, 2 parts of glycerin, and 2 parts of arsenite of soda.

Combating the olive fly, J. AGUET (*Coltivatore, 53 (1907), No. 19, pp. 586-590*).—In the author's opinion too little attention has been given to the natural enemies of the olive fly in the systems of artificial treatments which have been devised for its control.

Insects affecting park and woodland trees, E. P. FELT (*N. Y. State Mus. Mem. 8, vols. 1, pp. 1-332+a333-a459; 2, pp. 333-877, pls. 70, figs. 223*).—For a number of years the author and his assistants have been working on a comprehensive account of the insects of forest and shade trees. The present work is the most elaborate on the subject which has appeared in the United States since the fifth report of the United States Entomological Commission, by Doctor Packard. Both volumes are elaborately illustrated.

The subject material includes a general account of the biology of insects and the means of preventing their attacks and detailed economic discussions of all of the more important insects of forest and shade trees. These are classified primarily into borers, leaf feeders, and sucking insects, and again into the enemies of deciduous trees and coniferous trees. Bibliographical notes are given throughout the text, and a supplemental bibliography on forest insects is appended to volume 2 (pp. 701-755).

Wood wasps, R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 14 (1907), No. 2, pp. 98-104, figs. 4*).—The habits and life history of the genera Sirex and Xiphydria are briefly outlined. If these insects cause serious injuries to trees, their attacks may be partly prevented by removing and destroying or utilizing all diseased trees and fallen trunks and branches.

Occurrence of a sport in Melasoma scripta and its behavior in heredity, ISABEL MCCRACKEN (*Jour. Expt. Zool., 4 (1907), No. 2, pp. 221-238, pl. 1*).—The cottonwood leaf beetle has long been known to occur under a variety of color patterns. The frequent occurrence of pure black individuals indicates that this is a natural type of the species. This type does not adhere to Mendelian principles in inheritance, but behaves as a Mendelian recessive in first crosses.

The white-pine weevil, A. D. HOPKINS (*U. S. Dept. Agr., Bur. Ent. Circ. 90, pp. 8, figs. 6*).—The adults of *Pissodes strobi* appear in early May and feed upon the bark of the terminal shoots of white pine, later laying their eggs in the same situation. The adults are active for about 2 weeks. The white pine is the chief host plant, but cultivated spruces, jack pine, and other species of pine are sometimes attacked. The beetle is distributed from North Carolina to New Brunswick and westward to Wisconsin. Infested trees may be recognized by the abnormal development of the terminal shoots. The beetle does not breed in the bark of stumps. The method of treatment recommended by the author consists in collecting infested terminal shoots during the first half of July and placing them in barrels covered with screens so that the parasites may escape, after which the beetles are to be destroyed.

Some household pests, J. B. SMITH (*New Jersey Stas. Bul. 203, pp. 47, figs. 31*).—Practical notes and suggestions are given regarding the occurrence and means of combating the more important household insect pests, including roaches, ants, carpet beetles, moths, bedbugs, fleas, lice, flies, meal worms, larder beetles, white ants, powder-post beetles, centipedes, drug and cigar beetles, fish moth, and book lice. In the case of each one of these pests, notes are given on the life history of the insect and on the methods which have given best results in the hands of the author and other investigators. Suggestions are also made regarding general methods for the destruction of household insects, particularly by fumigation with sulphur and hydrocyanic-acid gas.

Second report upon the horseflies of Louisiana, J. S. HINE (*Louisiana Stas. Bul. 93, pp. 59, figs. 37*).—The purpose of the investigations reported in this bulletin was to obtain knowledge of the life history of horseflies which would serve as a basis for the formulation of practical rules for controlling these pests.

Horseflies appear to prefer swampy or wooded areas. One parasite was found attacking the eggs of Tabanus. *Monedula carolina* is reported as preying upon horseflies. Analytical keys are presented for the identification of the Tabanidæ of the United States and the species of Chrysops and Tabanus found in Louisiana. Each species is described with notes on its habits and life history.

Two little-known ticks of the Transvaal, C. W. HOWARD (*Transvaal Agr. Jour., 5 (1907), No. 19, pp. 581-584, pls. 2*).—An account is presented of the biology and economic relations of *Argas persicus* and *Ornithodoros savignyi cæcus*, the first species attacking fowls and the second being parasitic on man and other animals.

The fowl tick is very common throughout South Africa and is also widely distributed in other parts of the world. It is found on all kinds of domestic fowl, including also ostriches and canaries. *O. savignyi cæcus*, known by the common name of tampan, resembles the fowl tick but is considerably larger. It occurs in the dry and warm parts of South Africa and in some localities is a serious pest of man and domestic animals, particularly cattle and horses.

Sarcophaga caridei, a new species of fly parasitic on locusts, J. Brèthes (*An. Mus. Nac. Buenos Aires, 3. ser., 6 (1906), pp. 297–301, figs. 3*).—A technical description is given of the new species of fly under the name *Sarcophaga caridei*, parasitic on locusts. This constitutes the fourth species observed by the author as parasites of injurious locusts. Brief notes are included on the biology of this species.

Spraying, A. Dickens and R. E. Eastman (*Kansas Sta. Bul. 145, pp. 193–216, figs. 7*).—The orchards and vineyards of the Kansas Station have been regularly sprayed since 1887 and during this time Paris green, London purple, and arsenate of lead have been extensively used. Paris green is sometimes adulterated and the results obtained from London purple are not always uniform. Arsenate of lead has given the best results. The most satisfactory fungicide is Bordeaux mixture, and the best combination insecticide and fungicide is Bordeaux mixture and arsenate of lead. Details are given regarding spraying apparatus and a brief spray calendar is appended to the bulletin.

Spray calendar (*New York Cornell Sta. Bul. 245, pp. 127–136*).—The common garden, orchard, and ornamental plants are arranged in an alphabetical order with statements regarding the most important insects and fungus diseases to which these plants are subject and the most effective remedies for use in their control. Formulas are also given for the preparation of standard insecticides and fungicides.

The zoological bulletin of the division of zoology, H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 5 (1907), No. 1, pp. 32, pls. 3*).—Formulas are given for the preparation of standard insecticides and fungicides in the control of some of the more important insect pests and fungus diseases.

Fumigation of citrus trees with hydrocyanic-acid gas, F. Thomsen (*Transvaal Agr. Jour., 5 (1907), No. 19, pp. 710–715, pls. 3*).—Detailed directions regarding the formulas to be used in mixing the chemicals for the production of hydrocyanic-acid gas and also regarding the quantities to be used in tents over trees of different sizes.

The vetch as a honey plant, L. Lebreton (*Apiculteur, 51 (1907), No. 5, pp. 196–198, fig. 1*).—Notes are given on the extent of cultivation and the biology of different varieties of vetch. These plants furnish honey-bearing nectar in flowers and stipules. They are not honey plants of the first order, but are well worth considering.

Foul brood of bees, Maassen (*Mitt. K. Biol. Anst. Land u. Forstw., 2 (1907), No. 4, pp. 51–53, figs. 6*).—According to the author's investigations at least three organisms may be found in cases of foul brood. These are *Bacillus alvei*, *B. brandenburgiensis*, and *Streptococcus apis*. Further investigations will be made to determine the relative importance of these organisms in the production of foul brood.

Quarantine regulations against insects and plant diseases, J. T. Crawley (*Bol. Ofic. Sec. Agr. Cuba, 2 (1907), No. 5, pp. 315–327*).—A copy is given of the Cuban quarantine regulations promulgated on April 27, 1907, for the prevention of the introduction of injurious insects and plant diseases. The official method of generating hydrocyanic-acid gas and applying this remedy in the fumigation of plants is included.

Economic entomology and current literature, 1906, W. W. Froggatt (*Agr. Gaz. N. S. Wales, 18 (1907), No. 4, pp. 354–359*).—A brief review of some of the more important entomological literature of 1906, with particular reference to cattle ticks, mango weevil, cotton insects, and spray formulas.

FOODS—HUMAN NUTRITION.

Foods; their chemistry, analysis, and nutritive value, A. BALLAND (*Les Aliments. Chimie, Analyse, Expertise Valeur alimentaire. Paris: J. B. Baillière & Sons, 1907, vols. 1, pp. VII+432; 2, pp. 508*).—In this extended treatise on foods the author has summarized and discussed a large amount of available data regarding composition and nutritive value of foods and feeding stuffs.

Volume 1 contains cereals and products obtained from them, bread, and bakers' goods, and volume 2, vegetables, fruits, meat, dairy products, preserved foods, beverages, and feeding stuffs.

How may we best nourish ourselves? A. GAUTIER (*Rev. Sci. [Paris], 5. ser., 7 (1907), No. 11, pp. 321–326*).—The composition and properties of the more common food materials, the proportion of nutrients required, and related questions are discussed.

Formaldehyde in food materials, A. MONVOISIN (*Hyg. Viande et Lait, 1 (1907), No. 3, pp. 111–113*).—Data are summarized regarding the normal occurrence of formaldehyde in certain foods, particularly those which have been smoked. In the author's opinion the amount is so extremely small that it is of no importance from the standpoint of health. Data are also summarized regarding the determination of formaldehyde.

[**Food used in mountain climbing in Alaska**], F. A. COOKE (*Harper's Mo. Mag., 114 (1907), No. 684, pp. 821–837, pl. 1, figs. 13*).—In an article describing the first ascent of Mt. McKinley the author states that the ration allowance per man per day was 10 oz. of bread, 1 lb. of pemmican, 4 oz. sugar, 0.5 oz. tea, and 4 oz. "erbswurst," with 3 oz. wood alcohol for fuel. This allowance was so liberal that the food intended for 10 days was found sufficient for nearly 13 days. The pemmican used was made of equal parts of beef tallow and dried beef. The bread was specially prepared in camp and was baked in pellets not larger than a good-sized marble in a reflector in front of the fire until quite brown. The reflector was then moved farther from the fire and the bread dried until very hard. The dough used was made of flour and baking powder in the usual way, except that all shortening was omitted. "No grease was put in the pan nor the dough, for this seemed to prevent the drying process." The work performed on this ration was exhausting in the extreme.

[Calculated with the aid of average figures for the composition of the foods, the ration allowance furnished 208 grams protein and 4,790 calories of energy per man per day, or 167 grams protein and 3,835 calories of energy per day on the assumption that 10 days' food sufficed for 12½ days.]

Composition of East Indian food stuffs analyzed at the Colonial Museum, Haarlem, M. GRESHOFF, W. M. CLUWEN, and C. L. DE FOUW (*Bul. Kolon. Mus. Haarlem, 1906, No. 34, Sup.; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 7, pp. 433, 434*).—Rice, barley, buckwheat, and other cereals, dried chestnuts, St. John's bread, asparagus, portulaca, endive and other vegetables, raspberries, strawberries, cherries, and other fresh and preserved fruits, chocolate, wine, beer, shellfish, goat's milk, cream, sheep's milk, Swiss cheese, and other miscellaneous food stuffs were analyzed.

Studies on the digestibility and nutritive value of legumes at the University of Tennessee, 1901–1905, C. E. WAIT (*U. S. Dept. Agr., Office Expt. Stas. Bul. 187, pp. 55*).—Red kidney beans, white navy beans, and 3 varieties of cowpeas were used in the 72 digestion experiments with healthy men which are reported in this bulletin. The legumes constituted a large part of the simple mixed diet. The following table summarizes the results obtained:

Summary of results of digestion experiments with different legumes.

Character of diet.	Digestibility of total diet.			Digestibility of legumes alone.	
	Protein.	Fat	Carbohydrates.	Protein.	Carbohydrates.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Basal ration alone	91	95	98	....	....
Basal ration and kidney beans	78	89	95	77	94
Basal ration and white beans	81	88	95	78	96
Basal ration and cowpeas, whippoorwill	77	91	92	70	87
Basal ration and cowpeas, clay	81	93	94	74	88
Basal ration and cowpeas, lady	87	91	97	83	95

"In view of their richness in nutrient constituents, and the extent to which these are digested and absorbed by the body, the legumes deserve a high rank as important food materials. The present bulletin but demonstrates scientifically what has perhaps been long believed instinctively with regard to the value of white and kidney beans, but it also shows that whatever may be claimed for them may be claimed with at least equal fairness for the cowpea also.

"The cowpea has a distinctive and pleasing flavor and can be prepared for the table in a great many appetizing ways and compares favorably with other legumes in respect to both nutritive value and digestibility. Its wholesomeness and possible place in the diet is attested by its long and general use in the Southern States. Under usual crop conditions it is reasonable in price and it could undoubtedly be grown in quantities sufficient to meet any demand. The importance of beans, peas, peanuts, lentils, cowpeas, and indeed of legumes as a class is each year becoming more generally recognized as a source of protein in the diet, reasonable in cost as compared with common proteid foods of animal origin, and the use of legumes is increasing."

Potatoes and other root crops used as food, C. F. LANGWORTHY (*U. S. Dept. Agr., Farmers' Bul. 295, pp. 45, figs. 4*).—Potatoes, sweet potatoes, Jerusalem artichokes, tropical starch-bearing roots, such as cassava and yams, succulent roots, tubers, and bulbs, roots used as condiments, and similar food materials are included in this summary of data on the composition, digestibility, and nutritive value of root corps used as food.

Though not very nutritious in proportion to their bulk, root crops as a class, it is pointed out, offer some advantages over most other vegetable foods. They are so easily grown and are so productive that under ordinary conditions they sell at prices within the reach of all. Many of them may be kept over winter in such good condition that they are never out of season. The carbohydrates, the principal nutritive materials present, are in forms which are readily and well assimilated. The characteristic flavor which some of these vegetables possess is a decided advantage, as it makes the vegetables palatable and adds to the variety of the diet. Succulent vegetables of all sorts contribute bulk to the diet and so are valuable from the standpoint of hygiene, as within limits bulkiness is a favorable condition for normal digestion and also of importance in overcoming a tendency to constipation. In addition, the mineral salts which these vegetables contain serve an important purpose in helping to maintain the alkalinity of the blood and have other physiological uses.

Concerning the solanin content of potatoes and the effect of methods of cultivation on the formation of solanin in the potato plant, F. VON MORGEN-

STERN (*Landw. Vers. Stat., 65 (1907), No. 5-6, pp. 301-338*).—On an average, table varieties of potatoes contained 0.0125 per cent solanin and varieties suitable for farm animals 0.0058 per cent. The yellow varieties were found to contain less than red or blue. In general, the author believes that the more pronounced flavor of some varieties of potatoes is due, in part at least, to their higher solanin content. Small or unripe potatoes showed a greater percentage of solanin than full-grown tubers.

As regards methods of culture, it was found that humus, moisture, and potash tended to diminish the solanin content, while phosphoric acid and nitrogen increased it a little, though the effect of the phosphoric acid was very slight. Potatoes which had turned green owing to exposure to the light contained a considerably higher percentage of solanin than normal potatoes. Rotting neither destroyed nor appreciably diminished the solanin content.

Studies of the distribution and function of solanin in the potato plant showed that it occurs most abundantly in the growing and sensitive parts, and the author believes that it primarily serves as a plant protector, though it may also play a part in the assimilation of sugar.

Properties which determine the quality of wheat, A. CSERHATI (*Ztschr. Landw. Versuchsw. Österr., 9 (1906), p. 899; abs. in Chem. Ztg., 30 (1906), No. 102, Repert. No. 55, p. 462*).—Generally speaking, the gluten content of wheat is directly proportional to its protein content, but the proportion of gluten, according to the author, is not a satisfactory measure of the quality of the wheat.

The proteids of barley, their importance for the valuation of grain, and their relation to the steeliness of the barley, E. PRIOR (*Pure Products, 3 (1907), Nos. 2, pp. 92-98; 3, pp. 143-146; 4, pp. 192-195; 5, pp. 232-242*).—The following are some of the conclusions drawn from the extended series of investigations reported by the author:

"The content of water-soluble proteids and nitrogenous substances (leucosin, albumose, etc.) in the barley, and also the edestin-content of the barley, bears no fixed relation to the total protein content of the barley, and it varies within comparatively narrow limits.

"The hordein content of the barley and its content of insoluble proteid rises in general with the total protein content, as may be seen from the calculated average values for both proteids; numerous exceptions are, however, displayed.

"The amount of hordein + insoluble proteid in the barley rises and falls naturally with the total protein content of the barley.

"The percentage composition of the nitrogenous substances of the barley, heretofore designated as total protein, varies greatly and bears no relation to the total nitrogen content. . . .

"The causes of the apparent steeliness (degree of solubility) are the water-soluble, principally colloidal nonnitrogenous and nitrogenous bodies present in the endosperm of the barley, which caulk the starch-converting cells."

A fermented food made from rye flour, K. TEICHERT (*Centbl. Bakt.* [etc.], *2. Abt., 17 (1906), p. 376; abs. in Chem. Ztg., 31 (1907), No. 13, Repert. No. 11, p. 62*).—A Polish dish called "zur" is described, which is made by fermenting a rye-flour batter. After fermentation the dough-like material is cooked in hot water. The article includes a study of the bacteria involved.

The Bambarra groundnut, J. BURTT-DAVY (*Transvaal Agr. Jour., 5 (1907), No. 18, pp. 453-456*).—Analyses of the Bambarra groundnut (*Voandzeia subterranea*) and other data are quoted. According to the author, these nuts, which are similar to the peanut, though sometimes eaten raw, are usually boiled in two or three waters before they are eaten.

Concerning tea, A. D. MAURENBRECHER and B. TOLLENS (*Ber. Deut. Chem. Gesell., 39 (1906), p. 3581; abs. in Chem. Ztg., 30 (1906), No. 102, Repert. No. 55, p. 462*).—Java tea was found to contain 5.6 per cent pentosans on the dry matter basis. By extraction with hot water a trace of fructose, or cane sugar, and glucose was obtained. Hydrolysis with 6 per cent sulphuric acid gave arabinose, galactose, and glucose—so apparently araban, galactan, and glucose-yielding carbohydrate are present in tea leaves.

The carbohydrates of cocoa, A. D. MAURENBRECHER and B. TOLLENS (*Ber. Deut. Chem. Gesell., 39 (1906), p. 3576; abs. in Chem. Ztg., 30 (1906), No. 102, Repert. No. 55, p. 461*).—Cocoa beans freed from fat and shell, when hydrolized with 4 per cent sulphuric acid, yielded λ-arabinose, δ-galactose, and δ-glucose. The shells yielded λ-arabinose, δ-galactose, glucose, and xylose. A chlosterin isolated from cocoa butter had a melting point near that of phytosterin.

Rice, cleaning and polishing, H. McK. FULGHAM (*Bur. of the Census [U. S.] Bul. 61, pp. 49–58, dgm. 1*).—According to the statistical data presented, the total value of the rice products produced in 1905 was $16,296,916, an increase of 86.8 per cent over the values for 1900 to 1905. Processes of manufacture, historical and descriptive data, and other information are presented.

Beet sugar, Z. C. ELKIN (*Bur. of the Census [U. S.] Bul. 61, pp. 59–69*).—Statistical and other data regarding the present condition and distribution of the beet-sugar industry in the United States are reported. According to the figures presented the total value of the beet-sugar products in 1905 was $24,393,794, an increase of 233.1 per cent over the values for 1900 to 1905.

Canning and preserving fruits and vegetables, fish, and oysters, E. K. ELLSWORTH (*Bur. of the Census [U. S.] Bul. 61, pp. 9–48*).—The methods followed in canning fruits and vegetables, fish, and oysters are described. The commercial aspect of the enterprise is discussed with relation to its total amount and present development, the distribution of the industries, and related questions.

According to the data presented, the value of these canned products produced in 1905 was $108,505,471, an increase of 36.2 per cent over the values for 1900 to 1905 and of 98.7 per cent over the values for 1890 to 1900.

The preservation and ripening of meats, H. MARTEL (*Hyg. Viande et Lait, 1 (1907), Nos. 1, pp. 1–14, figs. 3; 2, pp. 53–67*).—The author describes and discusses the different systems of preserving meat by refrigeration and discusses the composition of fresh and refrigerated meat and similar questions.

The principal systems of preparing and preserving meat in use in the Argentine Republic, S. BALDASSARRE (*Arren. Econ. Indus. Freddo, 3 (1906), Nos. 29, pp. 997–1011; 30, pp. 1022–1024, figs. 28*).—The Argentine packing-house system is described and statistics given regarding the extent of the meat trade.

Starch sugar (glucose and grape sugar) as a food adulterant, H. LEFFMANN (*Jour. Amer. Med. Assoc., 48 (1907), No. 4, pp. 318, 319*).—A summary of data on the use of starch sugar is presented. The author believes that owing to possible contamination with sulphuric acid or sulphites this material may be dangerous and that its use should be forbidden in all cases where it merely cheapens the food or beverage.

The microscopical examination of flours and the determination of rice in wheat flour, E. COLLIN (*Jour. Pharm. et Chim., 6. ser., 24 (1906), No. 9, pp. 385–395*).—The detection by means of the microscope of rice flour, which the author states is often used in the adulteration of wheat flour, is described. Attention is drawn to the fact that sometimes rice flour mixed with bean flour is used as an adulterant.

Sulphuring rolled barley and polishing with talcum, F. HUEPPE and R. KRŽIŽAN (*Arch. Hyg.*, *59* (*1906*), *No. 4*, *pp. 313–336*).—A number of samples of barley grits were examined. In the authors' opinion the amount of sulphurous acid retained in sulphured grits is too small to produce a harmful effect. Grits thus treated sometimes have a bad appearance and therefore are polished with talc. Such treatment should be discouraged. Suggestions are made for legislation bearing on the subject.

Concerning the examination and valuation of marmalade, W. LUDWIG (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, *13* (*1907*), *No. 1*, *pp. 5–15*).—From the analytical data reported the author concludes that the proportion of material insoluble in water, the alkalinity of the ash, the acid content, the diminution of the water-soluble ash, and the alkalinity of the total and water-soluble ash furnish valuable data for judging the presence in marmalades of foreign bodies, particularly raspberry seeds, raspberry refuse, and apple pulp.

The production of artificial honey (*Bul. Assoc. Chim. Sucr. et Distill.*, *24* (*1907*), *No. 9*, *pp. 1255*, *1256*).—A method of inverting cane sugar with tartaric acid is described and the use of such material for mixing with natural honey is discussed.

The digestion of the proteids of cow's milk in infancy, F. X. WALLS (*Jour. Amer. Med. Assoc.*, *48* (*1907*), *No. 17*, *pp. 1389–1392*, *dgms. 3*).—From records of gains in weight, character of the feces, etc., noted in the case of infants fed different amounts of fat-free cow's milk, the author concludes that there is no evidence to show that the proteid of cow's milk causes any digestive disturbances with infants.

"All experiments prove that cow's proteid is easy to digest and resists putrefaction.

"In sterile fat-free milk we possess an unequaled therapeutic agent in the treatment of the nutritive disorders of infancy."

On zymoids, A. R. BEARN and W. CRAMER (*Bio-Chem. Jour.*, *2* (*1907*), *No. 4*, *pp. 174–183*).—Solutions of enzyms which have been heated to 56–60° C. for 20 to 30 minutes have a strongly inhibitory effect on the activity of the unheated enzym, according to investigations reported, if a sufficiently greater amount of heated enzyms is present. The property of inhibition is usually destroyed by exposure to a temperature of 100° C.

"The inhibition is not due to an antiferment. It is brought about by a reaction between the substrate and substances present in the inactivated enzym. These substances dialyze only very slowly through parchment. In the case of pepsin they are not specific for each species.

"These facts point to the existence of zymoids, which are probably preformed in the enzym preparations. Zymoids, like enzyms, differ in their resistance towards heat. Different enzym preparations vary in the amount of zymoids which they contain."

Influence of day or night feeding on the normal variation in body temperature, E. MAUREL (*Compt. Rend. Soc. Biol.* [*Paris*], *62* (*1907*), *No. 4*, *pp. 191–194*).—Bodily activity and diet, the author concludes from a summary of data and the results of his experiments with animals, are the principal conditions which affect diurnal variations in body temperature.

The toxicity of the primary products of digestion and the influence of certain foods upon muscular contraction, U. Mosso (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, *5. ser.*, *16* (*1907*), *No. 5*, *pp. 351–358*, *figs. 10*).—The ergographic experiments reported indicate that muscular power diminishes during the early stages of digestion, the depression varying with different foods. This effect, in the author's opinion, is caused by the action of the products of digestion upon the central nervous system and muscles.

Behavior of phytin in the organism, O. HORNER (*Biochem. Ztschr., 2 (1907), pp. 428–434; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 532, II, p. 118*).—From experiments with dogs it was concluded that 35 per cent of the phosphorus of phytin was absorbed. Similar results were obtained with rabbits, but the experiments were not complete.

The formation of glycogen in muscle, R. A. HATCHER and C. G. L. WOLF (*Jour. Biol. Chem., 3 (1907), No. 1, pp. 25–34, pl. 1, fig. 1*).—According to the authors' summary of their elaborate investigations, "glycogen is not formed in the perfusion of muscle by blood containing saccharose. Muscles rendered free from glycogen by starvation and strychnin do not form glycogen either from glucose or from saccharose. Glucose does form glycogen in muscle. The content of glycogen in symmetrical muscles is practically alike."

The fixation of creatin in muscle, F. URANO (*Beitr. Chem. Physiol. u. Path., 9 (1907), No. 3-4, pp. 104–115, figs. 4*).—The experiments reported showed that living muscle differed markedly from dead muscle in respect to the possibility of removal of creatin by dialysis, practically all of the creatin in the fresh muscle being in a form which could not be thus separated. When muscular tissue is cooked, free creatin is rapidly formed and much the same result is noted when the muscular tissue is kept on ice. It would seem therefore that some of the post-mortem chemical changes, grouped under the head of rigor mortis, are related to the differences in the way the creatin is bound to the muscular substance. Apparently in the living tissue the creatin is an integral part of the muscle protoplasm.

Creatinin and the reactions of sugar in urine, H. MCLEAN (*Bio-Chem. Jour., 2 (1907), No. 4, pp. 156–173*).—As shown by the experimental data reported, "creatinin is the substance in normal urine which most markedly interferes with Fehling's reaction in the presence of small amounts of sugar. Creatin, if present, has a similar, though less marked effect."

It is owing to the influence of creatinin that "normal urine reduces Fehling's solution after prolonged boiling, and clears up many reactions in which a precipitate appears after boiling for some time with Fehling's solution."

On diurnal and nocturnal variations in the excretion of uric acid, J. B. LEATHES (*Jour. Physiol., 35 (1906), No. 1-2, pp. 125–130, dgms. 2*).—The low output of uric acid and creatinin which was observed during the night "must be the expression of a diminished functional activity in some other organ or organs than the kidney. Nor does it seem probable for the same reason that the explanation is to be found in diminished blood pressure." The author states that experiments are now being carried on with a view to identifying the functions associated with the output of uric acid.

ANIMAL PRODUCTION.

Licensed concentrated feeding stuffs, 1907, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul. 149, pp. 19–25*).—A list is given of 86 brands of concentrated commercial feeds licensed for sale under the State law, together with their guaranteed protein and fat content. Some general suggestions are made for the purchase of concentrated feeds.

Comparative value of commercial feeding stuffs, V. RENNER (*Vrtljschr. Bayer. Landw. Rat., 11 (1906), No. 4, pp. 824–828*).—The author attempts to calculate on a money basis the comparative value of different feeding stuffs.

The substituting value of different concentrated feeding stuffs, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 13 (1907), No. 16, pp. 485–487*).—It is frequently necessary or desirable to substitute one concentrated feed for another in rations for farm animals, and the relative values of such materials are discussed and a table given showing the equivalent amounts of a number of varieties.

Experiments on the nutritive value of the nonproteid nitrogenous constituents of hay, M. Müller (*Jour. Landw., 55 (1907), No. 1–2, pp. 123–141*).—In continuation of earlier work (E. S. R., 17, p. 684), the amid products obtained from hay by extraction with water and purification with alcohol were studied in comparison with blood albumin in experiments with dogs. Judging by the gains in nitrogen and other recorded data, there was little difference in the two rations, and the author concludes that such nonproteid nitrogenous constituents of hay may be used for tissue building in the body and so may replace protein.

Additional experiments on the nutritive value of amids, M. Müller (*Fühling's Landw. Ztg., 56 (1907), No. 7, pp. 219–239*).—In a series of experiments subsequent to those reported above, the nitrogen gains on the amids occurring in hay were about twice as large as on free asparagin and about the same as on blood albumin. When such factors are taken into account, the author believes that amids can not be considered as having no nutritive value and that they must be grouped with protein rather than with the carbohydrates, as has been proposed.

The use of town refuse in animal feeding, Herter (*Deut. Landw. Presse, 34 (1907), Nos. 25, pp. 207, 208; 26, pp. 214, 215; 27, pp. 222, 223; 28, pp. 232, 233; 29, pp. 241, 242; 30, pp. 249–251; 31, p. 261*).—A summary and discussion of data regarding the value of food refuse and of municipal sewage-farm grass, and related questions.

Dried beet pulp molasses and denatured sugar in the feeding stuff of farm animals, Bouchon (*Sucr. Indig. et Colon., 69 (1907), No. 18, pp. 494–501, fig. 1*).—A summary and discussion of data on the use of sugar-beet products in the feeding of farm animals, with a description of the apparatus for drying beet pulp.

Molasses feeds, A. Schlicht (*Illus. Landw. Ztg., 27 (1907), No. 24, pp. 218–220*).—A summary of data regarding the composition and food value of molasses feeds. The author insists that the manufacturers should give definite data regarding the composition and quality of their products.

Materials employed to denature sugar for use in feeding farm animals (*Betterave, 17 (1907), No. 422, p. 113*).—Salt, oil cakes, meat meal, fish meal, and fish guano are among the products recommended for this purpose.

Maize as a fodder and silage crop, E. J. Russell (*Jour. Bd. Agr. [London], 14 (1907), No. 1, pp. 14–22*).—In a general summary and discussion of maize with reference to the needs of English cattle raisers, the author points out that large crops of this cereal can be grown in a number of districts in England.

In general the composition of maize somewhat resembles that of grass; "it depends on the season and is least satisfactory in cold, wet seasons when the crop is small, and most satisfactory in hot, dry ones when the crop is large. All classes of stock take to maize, and it is well worth a trial where succulent fodder is wanted during September.

"Maize can be converted into silage, which is quite a useful food, though inferior to roots and mangolds. In the process of manufacture the loss of dry matter was found to vary between 30 and 40 per cent, which loss falls mainly on the nitrogen-free extract and least on the fiber. Except when mangolds are unusually costly, it hardly appears worth while growing maize for the production of silage."

Analysis of ensilage from Biggenden State Farm, J. C. Brunnich (*Queensland Agr. Jour., 18 (1907), No. 4, p. 199*).—The samples of corn and of sorghum silage analyzed were 8 months old. The degree of acidity which was found was rather higher than usual, which, in the author's opinion, may be due to the fact that the quantities ensiled were small.

Concerning spoiled peanut cake, A. GRÉGOIRE, HENDRICK, and E. CARPIAUX (*Bul. Agr. [Brussels], 22 (1906), No. 7, pp. 953–974*).—Data are summarized regarding the composition and quality of spoiled peanut cake and its effect when fed. From the authors' analyses the conclusion was reached that spoiled peanut cake contains less than 6 per cent sugar in its organic material other than fat, and that the fat has an acidity greater than 60 per cent, calculated as oleic acid.

Yebb nuts from Somaliland (*Bul. Imp. Inst., 5 (1907), No. 1, pp. 19, 20*).—An analysis was made of the kernel of so-called yebb nuts, which indicated that they were likely to prove a satisfactory feeding stuff, since they contained about 13 per cent protein, of which nearly 12 per cent was true protein, in addition to some 10.8 per cent oil and 61 per cent carbohydrates. The nuts are used by natives as food. It was not possible to determine the botanical name.

Oil beans from southern Nigeria (*Bul. Imp. Inst., 5 (1907), No. 1, pp. 10–14*).—The proportion of oil present in oil beans or owala beans (*Pentaclethra macrophylla*) from southern Nigeria, the physical characteristics of the oil, and the composition of the meal remaining after the extraction of the oil are reported. The conclusion was drawn that there seemed no likelihood in the near future of a profitable market for these beans.

Blue agave as a famine fodder, J. M. HAYMAN (*Rpt. Agr. Sta. Orai, Jalaun [India], 1906, pp. 11–14*).—Tests made with boiled leaves of blue agave (*Agave lurida*) gave fairly satisfactory results. In the author's opinion this plant, which grows on waste lands, may have considerable value as an emergency feed in times of famine, but should be supplemented by other feeds.

Leaves of the coral tree as fodder (*Agr. Gaz. N. S. Wales, 18 (1907), No. 4, p. 361*).—An analysis by F. B. Guthrie of the leaves of the coral tree (Erythrina) is reported. The tree thrives in many localities, carries large quantities of foliage, and is readily propagated from cuttings. It has been suggested that the leaves might prove of value as stock feed during times of drought.

The water hyacinth [as a fodder] (*Queensland Agr. Jour., 18 (1907), No. 4, pp. 207–209*).—In a discussion of water hyacinth destruction and related questions a brief note is given on its feeding value. The concensus of opinion seems to be that this is not great.

Recent investigations on the feeding of farm animals, O. KELLNER (*Braunschweig. Landw. Ztg., 75 (1907), No. 12, pp. 51–55*).—In a paper presented before the general meeting of the Brunswick Central Agricultural Society, the author gives a summary and discussion of recent experiments in the feeding of farm animals.

Concerning the effect of different foods upon the structure of organs in the goose with special reference to food and functional activity, E. SCHEPELMANN (*Arch. Entwickl. Mech. Organ., 21 (1906), No. 3, pp. 500–595; 23 (1907), No. 2, pp. 183–226, figs. 47*).—The results of an extended series of investigations are reported in which geese were fed meat, grain, and mash.

The investigations as a whole, in the author's opinion, show that food may modify body structure and the functional activity of different organs. For instance, the pancreas in geese fed meat showed more marked development than in geese fed the other rations. The oil glands of geese fed the mash were somewhat heavier than those fed whole grain and about twice as heavy as those fed meat. In the case of the meat-fed geese the glands contained only a minute quantity of oil, which is probably explainable by the lack of fat in the meat diet. Extended bibliographies accompany the report.

Effect of partial starvation followed by a return to normal diet, on the growth of the body and central nervous system of albino rats, S. HATAI (*Amer. Jour. Physiol., 18 (1907), No. 3, pp. 309–320, fig. 1*).—In so far as the weight of the body and central nervous system are concerned the author concludes from the investigations reported that the effect of a 3 weeks' period of partial starvation on albino rats 30 days old is eventually completely compensated. "The chemical composition of the brain and spinal cord is, however, not entirely free from the effect, as is indicated by the higher percentage of water, and lower percentage of ether-alcohol extracts, in the experimental rats as compared with the controls."

Denatured sugar in the fattening of farm animals, H. LEGRAS (*Betterave, 17 (1907), No. 425, pp. 169, 170*).—Draft oxen fed denatured sugar as part of the ration in a 45-day test made an average daily gain of 1.516 kg. per head per day as compared with 1.352 kg. in the case of steers fed a linseed-cake ration without the sugar.

Fattening cattle on pasture, M. RASQUIN (*Jour. Soc. Agr. Brabant et Hainaut, 52 (1907), No. 18, pp. 505–508*).—A summary of data on the possibilities of fattening of cattle on pasture.

The use of skim milk in the fattening of calves, MALPEAUX (*Jour. Soc. Agr. Brabant et Hainaut, 52 (1907), No. 16, pp 459–461*).—A summary of recent data on the importance of skim milk in calf feeding when rightly used. Among other topics the hygienic value of the lactic acid of sour milk is considered.

Leaves as a sheep feed, H. ISAACHSEN (*Ber. Norges Landbr. Hoiskoles Virks., 1905–6, pp. 216–220*).—According to the author's analyses aspen leaves had the following percentage composition: Water 9.06, total protein 13.13, amids 0.80, fat 5.64, nitrogen-free extract 45.95, crude fiber 18.52, and ash 7.70 per cent. The percentage composition of birch leaves was water 9.03, total protein 12.22, amids 0.69, fat 9.05, nitrogen-free extract 48.20, crude fiber 17.21, and ash 4.29 per cent. Of the total protein of the aspen leaves 12.33 per cent was true protein and 7.32 per cent digestible protein. Similar values in the case of the birch leaves were 11.53 and 5.42 per cent. According to the author, 1 to 1.2 kg. of mixed poplar and birch leaves is equal for sheep feeding to 1 kg. of good meadow hay.—F. W. WOLL.

Sheep on paspalum grass, A. H. HAYWOOD (*Agr. Gaz. N. S. Wales, 18 (1907), No. 3, p. 234*).—In a brief note on Romney sheep at the Wollongbar Experiment Farm, it is stated that very satisfactory results have been obtained. The sheep mature early and produce a good fleece, the average weight being about 7 lbs. of wool. The carrying capacity of paspalum grass, "at a very low estimate, may be put at 10 sheep to the acre. Farmers in the district who have tried this breed speak very highly of them."

An experiment in feeding pigs, E. VOGLINO (*Coltivatore, 53 (1907), No. 15, pp. 456, 457*).—A brief note on gains made by two sows fed a mixed ration.

Different quantities of skim milk for pigs fed the same feeding stuffs, KLEIN (*Milchw. Zentbl., 3 (1907), No. 4, pp. 137–149*).—In 21 weeks the greatest gain, 0.611 kg. per head per day, was made by the pigs receiving the greatest quantity of skim milk, and the smallest gain, 0.582 kg. per head per day, was made on the smallest skim milk ration. A lot fed fish meal in addition to skim milk and grain gained 0.608 kg. per head per day.

Feeding experiments with dried potatoes, GAUL (*Deut. Landw. Presse, 34 (1907), No. 40, p. 325*).—From a feeding experiment with pigs, which is briefly reported, the conclusion is drawn that under local conditions dried potatoes may be profitably fed to pigs when they do not cost more than $1.50 per 100 lbs. and freight charges are not excessive.

Cotton-seed meal for poultry, T. W. Gaw (*Breeder's Gaz., 51 (1907), No. 20, p. 1125*).—On the basis of personal experience, the value of cotton-seed meal as a part of a dry mash for poultry is pointed out.

Improvement in horse breeding, S. O. Wood (*Jour. Dept. Agr. Victoria, 5 (1907), No. 3, pp. 138–152, figs. 5*).—Recommendations which include as special features the licensing of stallions and the discouragement of the exportation of mares were formulated after a study of the horse-breeding situation at home and abroad.

Intelligent management of plantation stables, W. H. Dalrymple (*Baton Rouge: Ortlieb's Printing House, 1907, pp. 20*).—In a paper presented before a meeting of the Louisiana Sugar Planters' Association, the author discusses the purchase of mules, care of manure, foods and feeding, water supply, the adjustment of different parts of harness and related questions with special reference to the comfort of the animals and the possibilities of greater profits from good management.

Taming zebras and their use in the Kongo state, H. Ross (*Tropenpflanzer, 11 (1907), No. 4, pp. 238–244, fig. 1*).—A summary of Nys' experiments with zebras which led to the conclusion that they may be tamed and made useful draft animals.

Ostrich growing and the production of ostrich feathers in the Cape of Good Hope, A. Ménégaux (*Rev. Sci. [Paris], 5. ser., 7 (1907), No. 16, pp. 491–495*).—Methods followed in ostrich raising on a commercial scale, ostrich breeding, the collection and care of the plumes, and similar questions are considered.

DAIRY FARMING—DAIRYING—AGROTECHNY.

The testing of cows, J. L. Hills (*Vermont Sta. Bul. 128, pp. 56–88*).—From the results of a study of nearly 700 yearly records and of over 400 lactations, the following directions are given for determining readily the annual yield of cows with sufficient accuracy for every practical purpose:

"Weigh the milk of each cow for three days monthly. At the end of the year add these results and multiply by 10, making such corrections for time of calving and drying off as circumstances indicate.

"Test the milk of each cow twice or thrice yearly, using two composite samples taken as follows:

"(a) For cows calving normally in the months of September to February inclusive and due to calve again in a reasonable time: in the third and fifth; or in the third and seventh; or in the second, fifth, and seventh; or in the second, fourth, and seventh; or in the third, fifth, and seventh months after calving. The outcome is likely to be within 0.30 per cent fat of the truth nine times in ten.

"(b) For cows calving normally in the months of March to August inclusive, and due to calve again in a reasonable time: in the third, fifth, and seventh months after calving. The outcome is likely to be within 0.30 per cent fat of the truth five times in six.

"(c) For cows calving normally and tending to go dry early: in the third and sixth months after calving. The outcome is likely to be within 0.30 per cent fat of the truth nine times in ten.

"(d) For cows which have aborted: in the third and fifth or in the third and sixth months after calving. The outcome is likely to be within 0.30 per cent fat of the truth nine times in ten.

"(e) For farrow cows when their condition does not follow abortion: any combination of the fourth or fifth month's test with that of either the thirteenth or fourteenth month linked with that of any month from the seventh to the eleventh inclusive. The outcome is likely to be within 0.30 per cent fat of the truth seven times in eight.

" In each case add the results and divide by the number of tests, two or three as the case may be, for calculated average test for the year."

The bulletin contains the summarized data and discussions upon which the above conclusions are based and also gives suggestions concerning weighing, sampling, and testing milk.

Milk yield and breast girth, E. Schnabel (*Milch. Ztg., 36 (1907), No. 26, pp. 304, 305*).—A maximum yield of milk was associated with a maximum breast measure in 27 out of 40 comparisons and with a minimum circumference in 8 comparisons. Five comparative tests showed no difference.

Report of the dairy institute at Hameln, 1906, P. Vieth (*Ber. Milchw. Inst. Hameln, 1906, pp. 39*).—The results of the various lines of work are briefly summarized and determinations of the fat content of the milk of 346 herds and comparative determinations of the fat in milk by the Gottlieb and Gerber methods are reported in full.

The action of dilute acids upon casein when no soluble compounds are formed, L. L. and D. D. Van Slyke (*New York State Sta. Tech. Bul. 3, pp. 75–153, figs. 15*).—The authors started out to determine the amount of acid which would combine with casein to form a definite compound insoluble in water, but failing to find a simple chemical combination they investigated the behavior of casein when brought into contact with different acids. The general scope of the work and the principal conclusions reached are summarized by the authors as follows:

" The behavior of casein was studied (1) with four acids of different dissociating power (hydrochloric, sulphuric, lactic, and acetic); (2) with N-125, N-500, N-1000, and N-2000 concentrations of these acids; (3) for contact of different periods of time, ranging from 5 minutes to 48 hours; (4) at different temperatures (0°, 25°, and 45° C.); and (5) with dilute solutions of neutral salts (potassium chlorid and magnesium sulphate). . . .

" It was necessary first to ascertain conditions under which casein forms soluble compounds with dilute acids in order to avoid such solution. Evidence of solution was shown (1) by viscosity of solution, (2) by behavior of solution on adding alkali, such as opalescent or milky appearance or precipitation, (3) by the xanthoproteic reaction, and (4) by deviation between results obtained by conductivity and by titration methods. In case of solution, titration results are untrustworthy for measuring the amount of free acid in solution because the dissolved proteid neutralizes per se part of the alkali used for titration, and also gives up to the alkali any acid with which the proteid may have combined. Little or no solution of casein occurs even on several hours' contact at 0° C. with solutions not stronger than N-500, or at 25° C. with solutions not stronger than N-1000. Degree of solution is increased (a) by concentration of acid, (b) by increase of temperature, and (c) by prolongation of contact. The solvent action of the four acids studied was in the following order, from strongest to weakest: Hydrochloric, lactic, sulphuric, and acetic. The rate at which casein dissolves in different acids of the same normality is not proportional to the concentration of the H^+ ions, or to the dissociation, but is disproportionately great for the weak organic acids. From solutions of equal strength, the dissolved proteid takes up a larger proportion of acid than does the undissolved. . . .

"Casein takes up acids from dilute solutions. For example, 1 gm. of casein, shaken with 100 cc. of N-1000 hydrochloric acid for 3 hours, takes from the solution nearly 50 per cent of the acid. The amount of acid thus taken up is not definite and fixed, but varies (1) with the concentration of the acid, (2) with the duration of contact until equilibrium is reached, which requires some hours, (3) with the degree of agitation until equilibrium is reached, (4) with the temperature, and (5) with the kind of acid. Some acid is always taken up, however small the amount of acid used; but the acid is never completely removed from the solution, however large the proportion of casein present. . . .

"The maximum amount of acid adsorbed by a gram of casein varies almost directly with the concentration of the acid within the limits used (N-125 and N-1000) in the case of hydrochloric, lactic, and acetic acids, so that at equilibrium the ratio of acid in 1 gm. of casein to the acid in 1 cc. of surrounding solution is nearly constant. In the case of sulphuric acid the ratio increases with dilution of acid. The equilibrium ratio reached when 1 gm. of casein is treated with 100 cc. of N-500 solution at 0°, is 675 for sulphuric acid, 147 for hydrochloric, 80 for lactic, and 36 for acetic. Equilibrium is reached in 2 to 24 hours, according to (1) the acid used, (2) the temperature, and (3) the degree of agitation. The greater part of the acid reacting is generally taken up in the first half hour or hour. Increase in temperature increases the rate at which equilibrium is approached, but decreases the final amount of acid taken up, when solution of casein does not result at the higher temperature. . . .

"The acid taken up by casein may be extracted by shaking with water. The extraction continues until the equilibrium ratio (concentration of acid in 1 gm. of casein divided by concentration of acid in 1 cc. of surrounding solution) is established, and then ceases. . .

"Neutral salts (potassium chlorid and magnesium sulphate) are not adsorbed from dilute solution by casein.

"The behavior of casein with dilute acids, when no solution occurs, suggests three different explanations: (1) an adsorption compound, (2) solution of acid in casein, or (3) a hydrolyzable salt of casein. A careful application of the experimental results to each of these hypotheses indicates that the action appears to correspond in detail only with the characterisics which apply to an adsorption.

"On the basis of this explanation, the proteid precipitated when milk sours is free casein in which lactic acid is held by adsorption."

The hydrolysis of the sodium salts of casein, L. L. and D. D. VAN SLYKE (*New York State Sta. Tech. Bul. 3, pp. 154–162, figs. 2*).—"In determining the amount of alkali neutralized by casein, different indicators give different results. Phenolphthaleïn has been in most common use in such work, giving higher results than other indicators. The object of the work presented was to determine the neutral point by means of conductivity measurements in comparison with the use of phenolphthalein and alkali. Our results indicate that the sodium salts of casein hydrolyze so readily that titration with alkali does not give the true equivalent weight of the proteid. An excess of casein, as of phosphoric acid, is required to overcome the alkalinity of the hydrolyzing normal salt. The point at which the alkalinity is overcome is indicated by the attainment of minimum conductivity and corresponds roughly with the point neutral to phenolphthaleïn. Because of the extreme weakness of its acid properties, markedly greater excess of casein is required to give an acid reaction with less delicate indicators."

The numerical determination of leucocytes in milk, A. R. WARD, MARGARET HENDERSON, and C. M. HARING (*Bien. Rpt. Bd. Health Cal., 19 (1905–6), pp. 142–156*).—The methods which have been proposed for the enumeration of leucocytes in milk are briefly described, with particular reference to their comparative accuracy and value.

According to the method proposed by Stewart a diseased condition of the udder was suspected if the milk showed more than 100,000 leucocytes per cubic centimeter. A comparison of the Stewart and Doane-Buckley methods showed that the latter method invariably causes much higher counts. Thus in 66 determinations according to the Stewart method in market milk, 9 samples showed no leucocytes and the highest number was 69,960 per cubic centimeter with an average of 5,459 for all samples. A direct comparison of the Stewart and Doane-Buckley methods during which 60 determinations were made in samples of market milk, showed an average according to the latter method more than 15 times as large as by the Stewart method. In one set of comparative tests the average number of leucocytes per cubic centimeter by the Stewart method was 5,610 on the first count and 4,800 on the second count, while from the same samples of milk the average count obtained by the Doane-Buckley method was 25,820.

A series of determinations were made by means of the Doane-Buckley method on samples of the milk of individual healthy cows during which an average count of 49,000 per cubic centimeter was obtained. When repeated counts were made from a given sample of milk the results obtained by the Doane-Buckley method were much more reliable than those yielded by the Stewart method.

The Doane-Buckley method was applied to an examination of mixed milk from dairies and individual cows in those dairies showing diseased udders. It was found that the milk from the diseased cows had no recognizable effect upon the leucocyte count of the mixed milk since most of the composite counts would be regarded as entirely normal, and the highest count obtained in one dairy was 191,000 per cubic centimeter. In another dairy one cow showed a count of 4,800,000 leucocytes per cubic centimeter, while the mixed milk of the same dairy showed only 19,000 per cubic centimeter. The author concludes that "it is not possible to detect udder disease in cows by the examination of a mixed milk for number of leucocytes alone." It is also held that the presence of streptococci in milk can not be considered as a proof of mammitis and that the microscopic examination of milk for staphylococci is of doubtful value.

Emulsions, R. Lezé (*Rev. Gén. Lait*, *6* (*1907*), *No. 10*, *pp. 217-224*).—This is a discussion of the theory of emulsions with special reference to dairy products.

Investigations on milk serum, F. Landolf (*Biochem. Ztschr.*, *4* (*1907*), *No. 2–3*, *pp. 172–195*).—From the results of earlier investigations and of those reported in this article the author is inclined to believe that lactose exists in milk in combination with both nitrogenous and nonnitrogenous substances rather than in a free condition. The preparations obtained by the author show great variations as regards polarization, reduction of Fehling's solution, and fermentation with yeast.

Bacteriological examinations of milk powder, G. Grosso (*Ztschr. Fleisch u. Milchhyg.*, *17* (*1907*), *No. 9*, *pp. 312–315*).—From samples of milk powder prepared by the Just-Hatmaker process the author isolated the following microorganisms: *Bacillus brevis*, *B. subtilis*, *B. amarificans*, *B. subbutyricus*, *Micrococcus varians*, *M. corrugatus*, and *M. eburneus*.

The composition of Irish butter during the winter months, J. H. Ball (*Analyst*, *32* (*1907*), *No. 375*, *pp. 202–208*, *figs. 3*).—Thirty-nine samples of butter made near Limerick from October 6, 1906, to March 26, 1907, showed Reichert-Meissl numbers varying from 21.9 to 30.9, Polenske numbers from 1.4 to 2.5, refractometer numbers from 41 to 42.5, and saponification numbers from 220.3 to 226.9.

Gathered cream for butter making, J. A. RUDDICK and G. H. BARR (*Canada Dept. Agr., Branch Dairy and Cold Storage Comr. Bul. 15, pp. 12, figs. 3*).—Suggestions are made concerning the proper handling and care of cream intended for factory butter making.

Some of the first chemical changes in Cheddar cheese, L. L. VAN SLYKE and A. W. BOSWORTH (*New York State Sta. Tech. Bul. 4, pp. 1–16*).—The authors studied the early changes taking place in the proteids of cheese and also changes in the calcium and phosphoric-acid compounds.

"Five cheeses were made at different times under the usual conditions observed in making Cheddar cheese. They were kept at 15.5° C. Determinations in cheese were made of the amounts of (1) total nitrogen, (2) nitrogen soluble at 55° C. in 5 per cent solution of sodium chlorid, (3) water-soluble nitrogen, (4) acidity of water-extract, (5) lactose, (6) total calcium and phosphoric-acid compounds, (7) water-soluble calcium and phosphoric-acid compounds, (8) calcium compounds in the salt-soluble portion, (9) calcium lactate, (10) total and water-soluble ash. . . .

"(1) The insoluble proteid of fresh cheese-curd (calcium paracasein) changes rapidly into a form soluble in 5 per cent solution of sodium chlorid at 55° C., until, in 9 or 10 hours after the cheese is put in press, the proteid, originally insoluble in the salt solution, becomes completely soluble in this solution. (2) Then the proteid soluble in salt solution changes into a form insoluble in salt solution, this change taking place rapidly at first and then gradually. (3) Proteids in water-soluble form appear to increase only slightly, if at all, until after the salt-soluble proteid has partially changed into the form insoluble in salt solution. . . .

"The calcium and phosphoric-acid compounds of cheese, insoluble at the start, become soluble until about 80 per cent of the calcium and all of the phosphates become soluble in water. This change is due to the formation of lactic acid and its action upon the phosphates of the cheese, resulting in the formation of monocalcium phosphate and calcium lactate. About 20 per cent of all the calcium in the cheese is found in the salt-soluble portion, and the proteid in this solution shows an acidity about equal to that shown by calcium paracasein."

The acidity of the water extract of Cheddar cheese, L. L. VAN SLYKE and A. W. BOSWORTH (*New York State Sta. Tech. Bul. 4, pp. 17–22*).—The acidity of the water extract of normal Cheddar cheese is attributed to monocalcium phosphate.

Chemical studies of Camembert cheese, A. W. BOSWORTH (*New York State Sta. Tech. Bul. 5, pp. 23–39*).—The bulletin is summarized by the author as follows:

"Camembert cheese can be made in the laboratory which compares very closely to the cheeses found upon the American market, to the cheeses imported from Europe, and to those worked upon by other investigators.

"The only function of the rennet in this type of cheese is to coagulate the milk.

"The bacteria are responsible for the most important chemical changes which take place in the cheese during its early history.

"The changes caused by the bacteria, directly or indirectly, are as follows:

"(a) Lactic acid is produced from milk sugar.

"(b) This acid as formed combines with some of the insoluble calcium which is present in a new cheese as phosphates and as calcium paracasein.

"(c) The lactic acid in combining with some of the calcium of the insoluble phosphates produces calcium lactate and soluble phosphates. These soluble phosphates are acid salts and increase the acidity of the cheese.

"(d) The production of lactic acid in some way, as yet not known, has an effect upon the calcium paracasein whereby it is completely changed into a form soluble in 5 per cent salt solution.

"(e) The further production of lactic acid changes this salt-soluble compound into a form insoluble in salt solution and water.

"The acidity of Camembert cheese is due mainly to two things: Paracasein and monocalcium phosphate ($CaH_4P_2O_8$).

"One of the characteristic differences in the making of Cheddar cheese and Camembert cheese seems to be the proper control of the production of the salt-soluble compound and of the subsequent change in this compound.

"Molds are responsible for that part of the ripening of the cheese in which the compact insoluble curd is changed in texture and becomes a soft creamy mass almost entirely soluble in water. This is due to enzyms produced by the molds."

Robbiole cheese of Valsassina, G. CORNALBA (*Indus. Latt. e Zootec., 5 (1907), No. 12, p. 91*).—This soft, highly prized, Italian cheese is briefly described and analyses of 2 samples are reported as follows: Water 46.56 and 45.37 per cent, fat 25.55 and 30.56 per cent, proteids 19.99 and 20.21 per cent, total ash 7.90 and 3.73 per cent, and sodium chlorid 5.80 and 1.22 per cent, respectively.

The relation of whey albumin to coagulation with rennet, S. SCHMIDT-NIELSEN (*Beitr. Chem. Physiol. u. Path., 9 (1907), No. 8-11, pp. 322-332*).—According to the author's investigations considerable so-called whey albumin is formed when rennet is allowed to act upon casein solutions. This may represent as much as 4 per cent of the nitrogen in the casein and is not dependent upon the rennet, as it may also be produced by coagulation with acids. It is looked upon as a cleavage product of the casein.

Whey albumose, E. FULD (*Biochem. Ztschr., 4 (1907), No. 4-5-6, pp. 488-499*).—The author reports the formation of a so-called whey albumose as distinguished from the whey albumin of Hammarsten during the coagulation by rennet of artificially prepared casein solutions.

Sanitary relations of the milk supply (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 111, pp. 7*).—This is a report of a committee appointed by the commissioners of the District of Columbia to investigate the local milk supply.

The report states that there is an opposition on the part of the trade to reasonable requirements, that there is proof that milk is a cause of disease, and that while Washington market milk compares favorably with the supply in other cities "there is abundant evidence to indicate that stale and infected market milk is everywhere responsible for a needless sacrifice of human life." The importance of low temperatures in keeping milk, certified milk, and the pasteurization of milk are also discussed. The committee favors pasteurization, except for milk obtained and handled by the best methods, and recommends the establishment within the District of a central plant for receiving and preparing all milk for distribution and for sterilizing milk cans and utensils.

Some suggestions are made to the public on home pasteurization and other measures designated as immediate safeguards.

The sanitary control of milk production, F. I. KAISER (*Illus. Landw. Ztg., 27 (1907), No. 46, pp. 415-417*).—This is a discussion of the more important conditions necessary for the production and sale of pure milk.

London milk, J. W. PECK (*Jour. Roy. Inst. Pub. Health, 15 (1907), No. 4, pp. 219-226*).—The author collected 101 samples of London market milk and examined them by the Gerber method and the cryoscopic method of Parmentier, concluding from his results that 68 samples had been skimmed and 89 had been watered. The average fat content of the samples was 3.66 per cent. Comment is also made on milk standards and on the improvement of milk supplies.

London milk, H. D. Richmond and C. Revis (*Jour. Roy. Inst. Pub. Health, 15 (1907), No. 5, pp. 268–272*).—The authors question the accuracy of the analytical data reported in the above article as well as the soundness of the conclusions reached.

Bacterial content of milk, Szász (*Abs. in Ztschr. Fleisch u. Milchhyg., 17 (1907), No. 10, p. 353*).—The author examined 150 samples of market milk in Budapest, finding an average bacterial content of 1,563,000 bacteria per cubic centimeter. The range was from 18,000,000 to 52,800.

Homogenization of milk, C. Istaz and G. Van Soest (*Rev. Gén. Lait, 6 (1907), No. 11, pp. 241–248*).—The literature of this subject is briefly reviewed and experiments are reported, the authors concluding that the acidity of milk is not increased by homogenization, that the chemical composition is not sensibly altered, and that if foreign fats have been added to market milk in this way the fraud has at least not been practiced on the samples examined by them. No real physiological advantages from homogenization have as yet been demonstrated.

Preservatives in milk, H. D. Richmond and E. H. Miller (*Analyst, 32 (1907), No. 374, pp. 144–154*).—The authors believe that the acidity of milk can be expressed with fair accuracy as a function of time and temperature. Between 15 and 35° C. the effect of temperature is quite regular, each rise of 10° increasing the rate of development of acid 2.075 times.

The authors have studied the effect of various so-called preservatives upon the souring of milk. The following substances apparently hastened souring: Sodium fluorid, acid-potassium fluorid, sodium sulphite, resorcin, and phloroglucin. The following had no appreciable preservative action: Phthalic acid, abrastol, sodium β-naphthol, sulphonate, and cyllin. The following had an appreciable preservative effect: Sodium benzoate, potassium benzoate, β-naphthol, salicylic acid, potassium metabisulphite, and borates.

In the authors' experiments milk kept at 30° C. became sour enough to curdle on boiling in 17 hours. The addition of 0.1 per cent of the following preservatives delayed the time of souring the number of hours indicated after each: Boric acid 10, benzoic acid 5½, salicylic acid 7½, β-naphthol 4½, and potassium metabisulphite 21. "When it is considered that the same effect can be attained by cooling the milk down a few degrees, at a cost which certainly does not exceed that of the preservative, it is evident that there is no justification for the use of preservatives in milk."

Notes are given on the detection and estimation of benzoates, β-naphthol, and boric acid.

Dairy inspection in Ireland, P. J. Howard (*Jour. Roy. Inst. Pub. Health, 15 (1907), No. 5, pp. 273–278*).—There is, according to the author, practically no dairy inspection in Ireland. The need of inspection is therefore discussed in this article and a simple system is briefly outlined.

The pasteurization and the inspection of creamery and cheese factory by-products, E. H. Farrington and E. G. Hastings (*Wisconsin Sta. Bul. 148, pp. 17, figs. 3*).—Methods of pasteurizing skim milk, buttermilk, and whey are briefly outlined and several arrangements for this purpose are described and illustrated. Suggestions are made concerning the removal of the foam from hot skim milk, and the feeding value of pasteurized skim milk is discussed. It was found experimentally that in pasteurizing skim milk by forcing steam into it about 10 per cent of water was added to the milk. Buttermilk in amounts not to exceed 5 per cent may be added to sweet skim milk and pasteurized without the mixture's curdling.

Various tests for the detection of pasteurized milk and whey are described. The potassium iodid-starch test is recommended for general use.

Disinfectants and the disinfection of dairies, K. TEICHERT (*Molk. Ztg., 21 (1907), No. 20, pp. 535–537*).—The advantages and disadvantages of various methods of disinfecting dairy apparatus and buildings are enumerated and tests of a proprietary disinfectant are reported.

Commercial products and their valuation with special reference to microscopy and technology, E. HANAUSEK (*Erdmann-König's Grundriss der Allgemeinen Warenkunde unter Berücksichtigung der Mikroskopie und Technologie. Leipzig: J. A. Barth, 1906, 14. ed., pp. XVI+930, figs. 416*).—This general treatise on the origin, valuation, and uses of commercial products, including precious stones, minerals, metals, inks, coloring matters, chemicals, and other inorganic materials, and foods, feeding stuffs, condiments, fats, oils, drugs, paper, tanning materials, leather, fertilizers, and other organic products of commercial importance, is designed as a reference handbook for use in technical and other schools and also for all who are interested in the technology of the subject and in its commercial aspects. In preparing the revision, material which has accumulated since earlier editions has been incorporated and the volume as a whole constitutes a valuable reference work.

Cider making in France, D. I. MURPHY (*Mo. Consular and Trade Rpts. [U. S.], 1907, No. 319, pp. 209–211*).—A brief description of the methods of cider manufacture, together with varieties of apples used for this purpose in France.

On the cause of the turbidity of wines, N. PASSERINI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 3 (1906), No. 4, pp. 365–373*).

VETERINARY MEDICINE.

Abstracts of work done in the laboratory of veterinary physiology and pharmacology, IV, P. A. FISH (*Ithaca: N. Y. State Vet. Col., 1907, pp. 67, figs. 3*).—The influence of sodium benzoate upon digestive fluids and upon metabolism was investigated by P. A. Fish (pp. 3–25 and 53–65). The digestion of starch and cane sugar was not greatly influenced by the presence of sodium benzoate to the extent of 0.5 per cent. The digestion of proteids was almost entirely checked by 1 per cent sodium benzoate. Large amounts of this drug increased metabolism and if continued may produce disturbances by interfering with the action of the liver.

In experiments with nuclein, L. S. Bachus (pp. 26–36) found that this substance causes a rapid increase in the number of white blood corpuscles, affecting the red cells to a slight extent and showing weak germicidal properties.

Experiments were carried out by P. A. Fish (pp. 37–41) to determine the physiological effect of arecolin hydrobromid. These experiments have already been noted from another source (E. S. R., 18, p. 98). Barium chlorid was tested as an antidote for nux vomica (pp. 42, 43). It was found to give almost immediate relief after the administration of fatal doses of nux vomica. About 15 grains of barium chlorid injected intravenously was necessary to counteract the effect of 4 gm. of nux vomica.

C. L. Roadhouse and L. Giltner carried on experiments to determine the value of bovine serum in cases of glanders (pp. 44–50). The blood serum of healthy cattle was used, and it was found that this serum caused no injurious effects aside from a slight reduction in the number of red blood corpuscles. The serum apparently imparts some power of resistance to glanders virus and therefore has value as a means of diagnosis, but is not capable of curing glanders.

Report on the investigations and work of the government veterinary service for 1904–5 (*Verslag. Bevind. en Handel. Veeartsenijk. Staatstoezicht,* *1904–5, pp. 246*).—A list is given of the names of veterinarians connected with the government service in Netherlands. The larger part of the report is occupied with a general account of the sanitary condition of animals throughout the kingdom with particular reference to the prevalence of tuberculosis, influenza, strangles, tetanus, hog cholera, gid, intoxications, etc.

A treatise on surgical therapeutics of domestic animals, P. J. CADIOT and J. ALMY, trans. by A. LIAUTARD (*New York: W. R. Jenkins, 1906, pp. XV+580, figs. 118*).—The translator of this volume considered the French edition as containing in a satisfactory form the information necessary to a thorough understanding of surgical therapeutics of domestic animals. The literature along this line in English is quite limited and the need was, therefore, felt for the translation.

The volume contains a general account of surgery, a special discussion of diseases common to all the tissues and diseases peculiar to certain tissues, particularly the extremities.

Veterinary toxicology, J. A. NUNN (*New York: W. R. Jenkins Co., 1907, pp. VII+191*).—The purpose of the present volume is to furnish a reliable compilation of material from all known sources regarding the effects and antidotes of the various mineral, animal, and vegetable poisons which may be of importance in veterinary medicine. The volume includes an account of general toxicology and the identification of poisons, and special chapters on metallic poisons, alkaline metals, mineral acids, gases, vapors, vegetable alkaloids, ergot, and other poisonous substances.

Meat inspection. As it is of interest to the State of Missouri, D. F. LUCKEY (*Mo. Bd. Agr. Mo. Bul., 5 (1907), No. 12, pp. 11*).—The purposes of meat inspection are to prevent the sale of diseased meat and the consequent spread of animal diseases, and to require cleanliness and hygienic methods in handling, preserving, and shipping meat and meat products intended for food. The chief results obtained by federal meat inspection are briefly noted, and attention is called to the duties of the State in supplementing the work done by the Bureau of Animal Industry.

The influence of pressure on the resorption of fluids in the subcutaneous connective tissue, M. H. J. C. THOMASSEN (*Inaug. Diss., Univ. Bern, 1906, pp. 54, figs. 2*).—The purpose of the experiments which constitute the basis for this dissertation was to determine the effect of pressure upon the rate of resorption of fluids injected under the skin. The author's experiments were carried out on young calves and the chemical substances used in solution in producing an edematous condition were nitrate, chlorid, and iodid of sodium.

It was found that when a mixture of equal volumes of sodium nitrate and chlorid in a solution isotonic with the blood was injected into the subcutaneous connective tissue, the rapidity of the blood current was diminished. When a sodium-nitrate solution was injected under increased pressure the rate of resorption into the blood was considerably increased, although, as already indicated, the blood current is somewhat slower. These results, therefore, indicate that in the resorption into the blood of fluids in the subcutaneous connective tissue the chief factors are diffusion, filtration, and osmosis.

The occurrence of eosinophilous leucocytes in inflammatory foci of the skin, C. TROESTER (*Ztschr. Veterinärk., 19 (1907), No. 4, pp. 153–156, figs. 2*).—The material which the author examined included sections of the skin of horses which had been cauterized shortly before preservation. In preparing the material the skin and underlying tissues were accidentally separated from one another. A microscopic study of sections taken 10 mm. from the cauterized point showed that the outer skin was normal while the Malpighian layer was somewhat thickened and showed a dissolution of the cell nuclei.

Second interim report of the royal commission appointed to inquire into the relations of human and animal tuberculosis, N. Foster et al. (*London: Roy. Com. Tuberculosis, 1907, pt. 1, pp. 98; abs. in Jour. Roy. Inst. Pub. Health, 15 (1907), No. 3, pp. 168–171*).—The royal commission was directed by the King of England to investigate and report on whether tuberculosis in animals and man is one and the same disease, whether it may be reciprocally transmitted, and under what conditions, if at all, such intertransmission occurs.

In the course of the investigations outlined in this report, which includes also a summary of previous investigations by the commission, tuberculous material has been used from 30 cases in cattle and 60 in man. The material thus obtained was employed in the form of emulsions or pure cultures in feeding experiments and by subcutaneous, intravenous, and intramammary inoculation. Both the bovine and human tuberculous material was tested on cattle and various other animals including guinea pigs, rabbits, rats, cats, dogs, goats, pigs, and monkeys.

Particular attention is given to the morphological and cultural variations observed in the tubercle bacilli as obtained from different sources. All of the details of these experiments of interest to investigators are given in an appendix to the report. The general result of the investigations thus far carried out indicate that "there can be no doubt but that in a certain number of cases the tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis; and there also can be no doubt that in the majority at least of these cases the bacillus is introduced through cow's milk. Cow's milk containing bovine tubercle bacilli is clearly a cause of tuberculosis and of fatal tuberculosis in man." In fact, in 14 out of the 60 cases of tuberculosis in man, the tubercle bacillus proved to be of the bovine type.

Human and bovine tuberculosis, with special reference to treatment by special kinds of tuberculin, N. Raw (*Tuberculosis, 6 (1907), No. 4, pp. 198–205*).—The author adheres to his view set forth in 1903 that human and bovine bacilli are two distinct types of a common species. This view has received confirmation, in the author's opinion, during the observation of 4,000 cases of pulmonary tuberculosis in man and a study of the origin of these cases.

It is maintained that tubercle bacilli of the human type produce pulmonary phthisis and ulceration of the intestines and abdominal glands, while bacilli of the bovine type produce tubercular peritonitis, tubercular meningitis, tuberculosis of the lymphatic glands, bones, and joints, and probably lupus. Acute miliary tuberculosis is also believed to be of bovine origin. The author holds that man is susceptible to both types of the bacilli and that bovine tuberculosis is frequently transmitted to man in infected food and by contagion. It is also held that the two forms of tuberculosis are somewhat antagonistic to each other so that a mild attack of one offers protection against the other. It has been found that tuberculin from man has a marked curative effect in bovine lesions and vice versa.

The danger from tubercle bacilli in the environment of tuberculous cattle, E. C. Schroeder and W. E. Cotton (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 99, pp. 24*).—The investigations reported in this paper were undertaken for the purpose of determining the extent to which tuberculous cattle may distribute tubercle bacilli in their milk, feces, or by other means. It was found that tubercle bacilli are readily disseminated in the feces. In fact the feces are considered the most dangerous factor in the spread of tuberculosis. Tubercle bacilli are present in the feces not only of cattle showing clinical symptoms of tuberculosis but also of cattle so slightly affected that the tuberculin test is required for diagnosis of the disease.

It was found that when cattle are fed material containing tubercle bacilli the micro-organisms are passed through the body and appear in the feces. The nasal discharge and the urine were found to be free from tubercle bacilli. In the opinion of the authors, milk from tuberculous cows does not contain tubercle bacilli, at least, as a rule, until the udder and structures connected with it are affected. In stables where tuberculous cows are kept, however, the feces contain sufficient tubercle bacilli to infect the milk in nearly all cases from the dust of the stable unless special precautions are taken.

It was shown that the feces of tuberculous cows contains sufficient tubercle bacilli to render milk pathogenic even when minute quantities of the feces are added to the milk. On account of the great danger from the spread of tuberculosis through the agency of the feces, it is recommended that all dairy cows be periodically tested with tuberculin and that all reacting cattle, regardless of their condition of health, be separated from healthy cattle and not used for dairy purposes.

Primary tuberculosis of the lungs and bronchial and mediastinal glands in young calves due to the ingestion of tuberculous virus, A. Chauveau (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 15, pp. 777–783*).—In connection with the evidence presented by recent investigators that pulmonary tuberculosis in animals and man may arise from infection through the alimentary tract the author calls attention to certain investigations which he made from 1868 to 1874 in which pulmonary lesions were brought about by the ingestion of tubercle virus without the production of any pathological conditions in the alimentary tract.

Inoculation of blindworms and snakes with human tubercle bacilli, J. Sorgo and E. Suess (*Centbl. Bakt. [etc.], 1. Abt., Orig., 43 (1907), Nos. 5, pp. 422–432; 6, pp. 529–547*).—In the long series of experiments carried out by the authors, human tubercle bacilli were found to cause true infection in blindworms and snakes. As a rule, tubercle bacilli of human origin did not become modified so as to produce an infection in warm-blooded animals. The author believes that occasional modification of this sort is a mutation in the sense of de Vries and that under ordinary conditions the tubercle bacilli from human beings and from warm-blooded animals are quite distinct.

The distribution of iodin in tuberculous animals, O. Loeb and L. Michaud (*Biochem. Ztschr., 3 (1907), No. 2–4, pp. 307–314*).—Several investigators have sought to obtain evidence regarding the question whether pathological processes exercise any specific attraction for drugs. In order to obtain some experimental data on this point the authors administered potassium iodid to rabbits after having previously inoculated them with tubercle bacilli. It was found that more iodin was stored up in the tubercles than in the healthy tissues. Similar results were obtained in experiments with guinea pigs. It appears, therefore, that tuberculous tissue has a high power of absorbing iodin combinations. The iodin thus absorbed is not in insoluble organic combination.

Taking samples of sputum by means of tracheotomy in diagnosing tuberculosis, A. A. Overbeek (*Tijdschr. Veeartsenijk., 34 (1907), No. 6, pp. 371–375*).—The author reports that in cattle suspected of being tuberculous, the use of a trocar inserted through the rings of the trachea will enable the operator to obtain bronchial slime which may be at once examined for the presence of tubercle bacilli. This method is recommended in examination of cattle intended for transport, in making a differential diagnosis between tuberculosis and pleuro-pneumonia, in examining dairy cattle and calves, and also calves used for the production of vaccine.

The etiology and vaccination for tuberculosis, A. Calmette (*Jour. Roy. Inst. Pub. Health, 15 (1907), No. 3, pp. 129–135*).—Apparently no domestic animal or man is entirely immune to tuberculosis. The opportunities for becoming infected, particularly by the ingestion of tubercle bacilli, are frequent, and on this account the author looks forward hopefully to the further perfection of a method of vaccinating animals and man against the disease.

Recent work on the etiology of tuberculosis and vaccination for that disease, H. Vallée (*Ann. Méd. Vét., 56 (1907), No. 4, pp. 205–221*).—The essential points established by recent investigation of tuberculosis are presented in a critical review. In the author's opinion it has been established that vaccination against tuberculosis is possible and credit is given to von Behring for being the first to demonstrate this fact.

Anthrax or charbon, W. H. Dalrymple (*Louisiana Stas. Circ. June, 1907, pp. 4, figs. 2*).—An account is given of the etiology, transmission, spread, period of incubation, symptoms, course, diagnosis, and treatment of anthrax.

Osteomalacia and rachitis of domestic animals, Liénaux (*Ann. Méd. Vét., 56 (1907), No. 4, pp. 193–200*).—Osteomalacia is observed in cattle, goats, sheep, and horses and may be produced by inoculation in small laboratory animals. Rachitis is known to occur in nearly all species of animals. Within recent years some evidence has been presented tending to show that these diseases are of infectious origin. Many cases have occurred in which no other reasonable explanation could be offered. It is believed, however, that the classical causes usually assigned for osteomalacia and rachitis may be predisposing factors in the production of these diseases.

Pseudofarcy among cattle in Sumatra, A Vryburg (*Rec. Méd. Vét., 84 (1907), Nos. 1, pp. 31–39; 7, pp. 241–248*).—According to the author's experiments, horses and chickens are refractory to this disease, while sheep, rabbits, and guinea pigs show a more or less intense reaction after inoculation with virus obtained from cattle. The natural mode of infection is not known with certainty. It appears that contact is not necessary to produce an infection. Serum obtained from immunized animals may be used in turn to immunize healthy animals, and after such immunization there is no necessity of isolation. Iodid of potash has no influence on the progress of the disease.

The toxin of the blackleg bacillus, P. Eisenberg (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 12, pp. 613–615*).—In experiments with rabbits and guinea pigs the author demonstrated that toxin of the blackleg bacillus may exercise its effects immediately, without a preliminary period of incubation. As a rule bacterial intoxications do not develop until after a period of incubation has been passed. Occasionally, however, the toxin acts at once in the manner of other animal and vegetable poisons.

Echinococcus in the heart of cattle and prophylactic notes, A. Pasquali (*Clin. Vet. [Milan], 30 (1907), No. 14, pp. 232–237*).—In a case observed by the author the clinical symptoms were not sufficient to permit of a reliable diagnosis. A post-mortem examination, however, disclosed the presence of echinococcus in the heart. Attention is called to the comparative ease with which the prevalence of this disease may be checked by the application of suitable prophylactic measures.

Johne's disease: A chronic bacterial enteritis of cattle, J. M'Fadyean (*Jour. Compar. Path. and Ther., 20 (1907), No. 1, pp. 48–60, figs. 10*).—Within the past few years it has been found that cattle are quite frequently affected with a chronic enteritis during which acid-fast bacteria are found in the mucous membrane of the small intestines. The bacteria have, at times, been suspected of being closely related to the tubercle bacillus. The lesions caused by them, however, are much less extensive, and inflammation is comparatively very slight. The author believes that the disease is strictly infectious, spreading from one animal to another, and recommends the careful isolation of affected animals.

The anatomy, biology, and pathological effects of Ixodes reduvius, C. K. BEINAROVICH (*Arch. Vet. Nauk [St. Petersb.], 37 (1907), No. 1, pp. 1–43, figs. 8*).—The life history of *Ixodes reduvius* is described in detail with particular reference to its agency in transmitting the blood parasite of Texas fever in Russia. This tick is a common parasite on cattle in Russia and is believed by the author to be the carrier of the blood parasite of Texas fever. Occasionally affected cattle are seen without any evidence of the tick, but the author believes that this is explained by assuming that such cattle had been previously bitten by ticks which had subsequently become engorged with blood and fallen to the ground.

The curative treatment of mammitis in cattle, G. P. MORETTI (*Clin. Vet. [Milan], 30 (1907), No. 12, pp. 193–196*).—The frequency with which mammitis appears in high-bred cows makes it desirable that practical means be devised for the treatment of this disease. The author reports good results from pumping filtered air into the affected quarter of the udder and upon giving hypodermic injections of chlorid of caffein combined with the administration through the mouth of iodid of potash in 20-gm. doses and the application of blisters to the outside of the udder.

Further notes on Piroplasma mutans—a new species of piroplasma in South American cattle, A. THEILER (*Jour. Compar. Path. and Ther., 20 (1907), No. 1, pp. 1–18, pl. 1*).—The author has continued his investigation of *Piroplasma bigeminum* and *P. mutans*. It appears from this study that animals which have recovered from Texas fever may be successfully inoculated with *P. mutans* at any subsequent date. This is considered as conclusive evidence that the two species are distinct. The author's observations in Cape Colony indicate that while the blue tick is instrumental in transmitting *P. bigeminum* from one animal to another, it does not carry *P. mutans*. At present it is not certain how the latter blood parasite is transmitted. It appears to be distributed widely over South Africa and Madagascar.

Control of rinderpest, G. E. NESOM (*Philippine Bur. Agr. Press Bul. 9, pp. 4–7*).—A serious outbreak of rinderpest occurred among the cattle and carabao of Occidental Negros. The method of simultaneous inoculation proved very effective in its control, but the presence of surra and septicemia made it dangerous to continue this work except in localities where the last-named diseases did not prevail. In all, 5,780 cattle and carabaos were inoculated, and of this number only 4 per cent subsequently died of rinderpest.

Septic pneumonia of calves, SCHREIBER (*Monatsh. Prakt. Tierheilk., 18 (1907), No. 6–7, pp. 299–329*).—The literature relating to this subject is critically discussed in connection with a bibliography of 81 titles. The symptoms and etiology of the disease are described, and notes are given on the results obtained from the use of a method of vaccination. The micro-organism which causes the disease is *Bacillus vitulisepticus*. The vaccination method recommended by the author has given satisfactory results in nearly all cases, and consists in the use of septicidin.

Cysticercus tenuicollis in sheep, F. CLUTTERBUCK (*Jour. Dept. Agr. West. Aust., 15 (1907), No. 3, pp. 204–206, pl. 1*).—The life history of *Tænia marginata*, which is the adult form of the sheep bladder worm, is reviewed and suggestions are made regarding the inspection of mutton for the presence of the bladder worm and the treatment of dogs in order to prevent the further spread of this parasite.

Gid in sheep, E. J. DOMMERHOLD (*Tijdschr. Veeartsenijk., 34 (1907), No. 6, pp. 375–382*).—This disease, which occurs quite commonly in sheep and cattle, and sometimes in goats, may be cured by the removal of the parasitic worm from the surface of the brain. This is accomplished by trepanning the skull. The operation may be carried out successfully on either sheep or cattle.

An epizootic mammitis of sheep caused by bacteria, Dammann and Freese (*Deut. Tierärztl. Wchnschr., 15 (1907), No. 12, pp. 165–170*).—An epizootic mammitis was observed in sheep on an estate where it had prevailed for a number of years. The disease commonly appeared in ewes when the lambs were about 4 to 6 weeks old. A bacterial organism was isolated from the udder of affected ewes and proved to be pathogenic when injected into the udder of healthy ewes. When, however, healthy ewes were kept in the same pen with diseased animals the infection did not spread. Notes are given on the behavior of the pathogenic micro-organism on various nutrient media.

A note on the inter-communicability of ovine and caprine variola, W. H. Flook (*Vet. Rec., 19 (1907), No. 978, p. 648*).—Brief mention is made of instances in which variola has been observed to spread from sheep to goats, or vice versa. Attention is called to the fact that in inspecting sheep or goats for the possible presence of variola, the brisket should always be carefully examined.

The histology and physiology of normal pigs' blood, W. Giltner (*Jour. Compar. Path. and Ther., 20 (1907), No. 1, pp. 18–23*).—As a basis for the study of the reactions of the blood in disease, it is necessary to establish beyond dispute all of the normal conditions which may be found in the blood. The author's observations along this line were undertaken to determine the relative number of red and white blood corpuscles, the specific gravity of the blood, the size of the red blood corpuscles, and other points. During this study, the blood of 24 normal pigs was studied and the results of the observations are presented in a tabular form.

Increasing the resistance in protective vaccination against swine erysipelas, M. Prettner (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 2 (1907), No. 4–5, pp. 353–359*).—According to the experiments reported in this paper the resistance of the animal organism toward swine erysipelas becomes higher the more active the part taken by the organism in the process of immunity. The degree and duration of this resistance apparently depends upon the relation between the quantity of serum and culture used in the simultaneous method. The smaller the quantity of serum the more pronounced the active immunity which results. In the author's opinion the simultaneous method of vaccination for swine erysipelas produces an essentially passive immunity.

Trichina inspection in southern Germany, J. Böhm (*Wchnschr. Tierheilk. u. Viehzucht, 51 (1907), No. 12, pp. 221–226*).—It has been commonly reported that hogs affected with trichina are exceedingly common in southern Germany and that the disease is almost unknown in man in that region. In the author's opinion this condition of affairs no longer prevails. Notes are given on a number of outbreaks of trichina among human beings and recommendations are made regarding the sanitary supervision of farms in order to prevent the infestation of hogs with trichina.

The horse; its treatment in health and disease, J. W. Axe (*London: Gresham Pub. Co. [1907], vols. 5, pp. XIV+161–320, pls. 8, figs. 100; 6 pp. XIV+321–491, pls. 9, figs. 59*).—The four preceding volumes of this work have been already noted (E. S. R., 18, p. 583). The present volumes contain an account of ring worm, mange, and some of the intestinal parasites of the horse and a detailed discussion of the structure and diseases of the bones and muscles. Special chapters are given on diseases of the joints and feet, wounds, materia medica, and antiseptics.

Intoxication produced by dead glanders bacilli in the stomach, J. Cantacuzène and P. Riegler (*Ann. Inst. Pasteur, 21 (1907), No. 3, pp. 194–210*).—In studying the toxic effects of dead glanders bacilli, the author made use of guinea pigs as the experimental animals. Detailed notes are given on the technique of laboratory methods and on the symptoms produced by the use of the dead glanders bacilli.

It is found that dead glanders bacilli are toxic and when used in large quantities produce a rapidly fatal result, whether inoculated into the peritoneum or given through the mouth. The chief symptoms are fever, emaciation, necrosis of the white blood corpuscles, and hypertrophy of the lymph glands. Although the dead glanders bacilli produce extremely toxic effects, they are rapidly destroyed by the white blood corpuscles. The penetration of these bacilli through the intestinal walls takes place largely in the ileum and cæcum.

Glanders in 1907, R. PORCH (*Vet. Rec., 19 (1907), No. 980, pp. 681–684*).—Glanders prevails throughout England but is observed with special frequency in and around London. Since 1891 the loss of 46,898 horses has been reported from this disease alone. The author considers it an unnecessary loss since practical means for the control of the disease are known and the veterinary service is of sufficient extent to eradicate glanders provided a systematic attempt is made to do so.

Osteoporosis in animals, H. INGLE (*Jour. Compar. Path. and Ther., 20 (1907), No. 1, pp. 35–48*).—Chemical analyses were made of the bones of a number of healthy and diseased horses, mules, and jacks. From these anlayses it appears that the presence or absence of osteoporosis could be determined with certainty by the chemical composition of the bones. No micro-organism has been definitely associated with this disease, and the cause appears to be found in defective nutrition.

In the bones of horses suffering from osteoporosis there is an actual deficiency of lime and phosphoric acid, but the author proposes the theory that the abnormal condition of the bones is brought about by the use of foods not necessarily deficient in lime or phosphates, but in which the ratio of lime to the phosphoric acid is too low. This would be the case where the ration consists too exclusively of oats and corn. In such a ration the proportion of phosphoric acid to lime is altogether too high. The author suggests that in localities where animals suffer from osteoporosis farmers should avoid the use of an exclusive ration of oat-hay and corn, and should supplement the deficiency in basic materials, particularly lime, by the addition of grass-hay, or better, by the use of alfalfa.

Osteoporosis of solipeds, A. THEILER (*Monatsh. Prakt. Tierheilk., 18 (1907), No. 5, pp. 193–209, figs. 4*).—The pathological anatomy of this disease is described in detail. Osteoporosis affects horses and other solipeds of both sexes and all ages and in the form usually observed in South Africa appears not to be connected with the kind of feed used. The author believes that the lack of bone-building salts can not be considered as the cause of the disease. Inoculation experiments, however, fail to cause an infection. In advanced cases, medical treatment seems to be of no avail, but in the early stages of the disease a decided change of location and climate may bring about some improvement.

Indian equine piroplasmosis, A. J. WILLIAMS (*Jour. Compar. Path. and Ther., 20 (1907), No. 1, pp. 23–35, charts 5*).—A general account is presented of the prevalence, symptoms, course, and etiology of this disease. In treating the disease, good results are reported from the use of quinin in large doses at the outset, decreasing the dose after the first few days, and adding suitable tonics. It is desirable that animals should be kept quiet during the treatment. Thus far little work has been done in India regarding the etiology of equine piroplasmosis, and the means of transmission of the disease are not known.

A piroplasmosis of the horse in Italy, L. BARUCHELLO and N. MORI (*Centbl. Bakt. [etc.], 1. Abt., Orig., 43 (1907), No. 6, pp. 593–604*).—A piroplasmosis which occurs during the summer months in the vicinity of Rome and has been referred to under various names, such as typhoid fever, influenza, etc., is caused by a blood parasite which may prove to be *Piroplasma equi*, but the species has not been definitely determined.

The treatment of different forms of pneumonia in the horse, M. V. DROUIN (*Rev. Gén. Méd. Vét., 9 (1907), No. 103, pp. 369–384*).—The most serious forms of pneumonia in the horse are the form which follows strangles and that commonly designated as typhoid. The author describes the symptoms which ordinarily appear in cases of pneumonia, and presents a general summary of recommendations regarding methods which have given beneficial results in different cases. The results obtained from serum treatment and vaccination are thus far not quite satisfactory, although somewhat encouraging.

The etiology of strangles in horses, L. BARUCHELLO (*Rev. Gén. Méd. Vét., 9 (1907), No. 104, pp. 433–447*).—In the various forms under which strangles occurs a staphylococcus is frequently found associated with the streptococcus which has been considered as the cause of the disease. The author found that both of these micro-organisms could easily be isolated from the blood of affected animals. Apparently the streptococcus of strangles can not be differentiated from *S. pyogenes* and the staphylococcus is also referred to as *S. pyogenes*. Mixed cultures of the two pathogenic organisms are more virulent than pure cultures of either organism taken separately. The sterile filtrate of the staphylococcus contains very toxic substances and pure cultures of the streptococcus are greatly increased in virulence by the addition of some of this toxin. The author believes as a result of his experiments and observations that the great variation in the symptoms in different cases of strangles is largely due to the result of the complex action of the two associated organisms.

Poisonous effects produced by aloes in a case of strangles, M. ALBRECHT (*Wchnschr. Tierheilk. u. Viehzucht, 51 (1907), No. 15, pp. 281–286*).—Drugs which ordinarily in medicinal doses produce well-known harmless effects occasionally induce dangerous symptoms in individual cases. Brief notes are given on the effects observed from the administration of aloes. In two cases which came under the author's observations dangerous intoxication was produced by the administration of the usual dose of aloes in cases of strangles.

Bowel lesions in the horse due to a Strongylus, A. J. BECKETT (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 3, pp. 203–206, fig. 1*).—The symptoms produced by infestation with Strongylus in the horse are vague and not characteristic. They may resemble those of colic or enteritis. As soon as the parasite worms are noticed, it is necessary to adopt preventive measures in order to check the further spread of the disease. Great importance attaches to the isolation of diseased animals, since otherwise the farm where the disease occurs may become generally infested.

Tetanus, J. L. WEBB (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 2, pp. 95–99, figs. 2*).—The cause, symptoms, period of incubation, and treatment of this disease are briefly discussed. The author recommends the prompt antiseptic treatment of all wounds in localities where tetanus is to be feared. The results thus far obtained from the use of antitetanus serum are somewhat contradictory.

The three stages in the aerobic life of the tetanus bacillus, G. ROSENTHAL (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 12, pp. 578–580*).—Distinction is made between the three stages which succeed one another in the culture of the tetanus bacillus under aerobic conditions. For a short time the bacillus retains its ordinary characters intact. Its chemical, biological, and pathogenic properties are even retained during 5 or 6 transfers. Following upon this stage there is a period during which the bacillus gradually loses its functions, but still retains, at least in many instances, the power of regaining its original pathogenic properties. In the third stage the bacillus develops as an aerobe, but has lost its original characters entirely.

Polyneuritis of chickens and beri-beri, a chronic oxalic-acid poisoning, G. MAURER (*München. Med. Wchnschr., 54 (1907), No. 15, p. 731*).—In experiments conducted by the author evidence is furnished that polyneuritis of chickens is caused by chronic poisoning with oxalic acid. It was found that when rice and other cereals were fed to excess after having the outer coat removed, the symptoms of polyneuritis developed. This is interpreted as meaning that oxalic acid is not counteracted for the reason that its natural antidote, lime, is largely removed with the outer coat of the grain.

The germicidal value of liquor cresolis compositus (U. S. P.), C. N. MCBRYDE (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 100, pp. 24*).—In the disinfection of cattle cars, the Bureau of Animal Industry has previously used a mixture of lime and carbolic acid, but on account of some objections to this disinfectant a test was made of liquor cresolis compositus, which is described as a liquid soap containing 50 per cent of cresols. This disinfectant was carefully tested by the drop and rod methods and compared with the efficiency of carbolic acid alone and a mixture of carbolic acid and lime. In these comparative tests it was found that carbolic acid was considerably diminished in germicidal efficiency by the addition of lime. The bacteria used in comparing carbolic acid and a mixture of the same disinfectant with lime were *Staphylococcus pyogenes aureus* and the hog cholera bacillus.

Liquor cresolis compositus, as described in the United States Pharmacopœia, contains 500 gm. of cresol, 350 gm. of linseed oil, 80 gm. of potassium hydroxid, and enough water to make 1,000 gm. In experiments with this mixture it was soon found that the higher the boiling point of the cresol the more efficient the disinfectant. Tests were made with a number of organisms, including *Bacillus pyocyaneus*, *B. coli communis*, *B. typhosus*, *B. tuberculosis*, and *B. choleræ*

Liquor cresolis compositus was found to be strongly germicidal for all of these bacteria. It varies somewhat in its efficiency depending on the boiling point of the cresol, but the germicidal value of the lowest form of cresol is 1½ times greater than that of carbolic acid.

RURAL ECONOMICS.

The initiative of the King of Italy and the International Institute of Agriculture, A. DE VITI DE MARCO ET AL. (*L'Iniziativa del Re d'Italia e l'Istituto Internazionale d'Agricoltura. Rome: G. Bertero, 1905, pp. X+732; rev. in Polit. Sci. Quart., 22 (1907), No. 2, pp. 348–350*).—The information contained in this treatise was compiled at the request of the King of Italy as a basis for determining the best plan and constitution of a proposed international institute of agriculture. The volume is divided into two parts. The material presented in part 1 relates to the production and distribution of agricultural products, the methods and advantages of irrigation, cooperative credit and insurance societies, agricultural organizations, and other matters bearing on the economic life of the rural population in Italy, France, Great Britain, United States, Austria, Germany, and Holland. Statistics are given in detail on these subjects up to the close of the year 1904.

In part 2 are discussed the functions of an international institute of agriculture by means of special articles on the following topics: The international development of cooperation, by A. Bertolini; the international development of insurance against damage from hail, by U. Broggi; the organization for marketing grain in the international congresses of agriculture, by G. del Vecchio; the international agricultural union and the project of Professor Ruhland, by the same writer; notes on the agricultural statistics of England and the United States, by C. Dragoni; and the agricultural migratory tendencies between various countries, and the grouping of emigrants, by A. Bosco di Ruffino.

The volume as a whole furnishes detailed information regarding the organization of agriculture in the countries mentioned.

Agricultural cooperation in Austria-Hungary, U. Paluani (*Bol. Quind. Soc. Agr. Ital., 12 (1907), No. 9, pp. 351-357*).—The author discusses the development of agricultural cooperation in Austria and Hungary from 1880 to 1906, with particular reference to the Raiffeisen agricultural credit banks, cooperative dairies, grain associations, and societies for the marketing of eggs, though numerous other forms of cooperation are mentioned.

Statistics show that there were in Austria in 1905, 4,300 cooperative credit banks, with deposits aggregating 310,000,000 crowns, while in Hungary in 1906 the number was 1,814, with 453,929 members and a capital of about 18,000,000 crowns. At the close of 1904 the cooperative dairies in Hungary numbered 584 with about 56,000 members, and the number of egg societies was 264 at the close of 1906. In no country in the world, it is said, is agricultural cooperation so completely developed, so systematically organized, and so accurately classified as in Austria-Hungary.

Danish cooperative associations for producing and marketing agricultural products, T. Brinkmann (*Fuhling's Landw. Ztg., 56 (1907), No. 8, pp. 255-273*).—Statistical data with discussion relating to the development of cooperative associations for the production and sale of milk, eggs, and meat. The figures indicate a gradual increase in the number of associations, membership, and extension of trade from 1900 to 1906. The present success of Danish agriculture and the improvement in the quantity and quality of the products are attributed in great measure to the operation of cooperative societies.

Agricultural organization in Natal (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 5, pp. 523-526*).—The organization and purposes of the mealie growers' union, fruit growers' union, wattle growers' association, and a cooperative bacon factory in Natal are reported. The general objects of the associations are to facilitate the marketing of products, to disseminate information among producers, to secure a reduction in freight rates, to supervise the inspection and grading of products, and to secure greater returns to producers by saving the profits of middlemen.

The real state of cooperative agricultural credit in France, Gilliéron-Duboux (*Chron. Agr. Vaud, 20 (1907), No. 10, pp. 203-208*).—The author points out in this article how the agricultural credit banks are aiding the peasant classes in France, particularly by furnishing credit on personal security at 4 or 4½ per cent interest.

The progress of the movement is shown by the following summary: In 1900 there were 9 district banks, 87 local banks, 2,175 members, and 1,910,456 francs advanced in loans; at the close of 1905 there were 66 district banks, 1,355 local banks, 61,874 members, and 44,162,573 francs advanced in loans. The figures for the first 6 months of 1906 also show a proportionate rate of increase.

Report on the agricultural bank of Egypt, E. W. Kemmerer (*Ann. Rpt. Philippine Com., 7 (1906), pt. 1, pp. 643–695*).—This report describes the economic conditions of the peasantry in Egypt prior to the establishment of the agricultural bank in 1902, and gives an account of its organization, control, and operation since that date. The author expresses his belief that it would be advisable to establish "an agricultural bank in the Philippines along lines similar to that of the agricultural bank of Egypt."

Cooperative banks for agriculture (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 3, pp. 245–251*).—A discussion of some of the results accomplished in promoting the economic welfare of the poorer classes of farmers and tenants by the establishment of agricultural cooperative banks.

Land banks versus credit banks, E. T. MULLENS (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 5, pp. 485–488*).—The difference in functions of land banks and credit banks and the advantages of their establishment in Natal are discussed. The former advance money on the security of freehold land to proprietors, while the latter, as mutual loan societies, primarily seek to aid tenant farmers on the basis of personal credit.

The need for farm statistics in estimating the cost of production (*Rhodesian Agr. Jour., 4 (1907), No. 4, pp. 333–344*).—This article was compiled on the basis of Minnesota Station Bulletin 97 (E. S. R., 18, p. 686), with changes made to make its facts and principles applicable to the conditions in Rhodesia.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 9 (1907), No. 8, pp. 57–64*).—Data on the condition of crops and on the supplies, value, and prices of agricultural products in the United States and foreign countries are summarized and discussed. A table gives the principal groups of domestic exports of farm and forest products during the fiscal years 1906 and 1907.

Kansas—her story and statistics (*Quart. Rpt. Kans. Bd. Agr., 26 (1907), No. 101, pp. 444, map 1*).—Detailed information of each county of the State as regards area, population, resources, railways, products, public lands, etc., with a history of the development of Kansas since 1865. The report also contains the addresses, papers, and discussions at the annual meeting of the Kansas State Board of Agriculture, January 9–11, 1907, and a résumé of commercial sugar-beet production in Kansas. The statistical data regarding agriculture have been noted from another source (E. S. R., 18, p. 1171).

Tenth report of the Bureau of Agriculture, Labor, and Industry of the State of Montana, J. A. FERGUSON and L. P. BENEDICT (*Rpt. Bur. Agr., Labor, and Indus. Mont., 10 (1906), pp. VI+478, pls. 29, figs. 25*).—This is a detailed report on the lands, irrigation, agriculture, labor, industries, and other economic and social forces of Montana for the year ending November 30, 1906.

The various agricultural industries and methods of culture practiced are described, accounts are given of the farmers' organizations, creameries, live stock, and wool production of the State, and statistics are presented and discussed for the purpose of showing the State's agricultural development which "warrant the prediction that Montana is destined in the near future to take high place among the really great agricultural States in the Union."

Annual bulletin of the Nebraska Bureau of Statistics, B. BUSH and D. C. DESPAIN (*Ann. Bul. Bur. Statis. Nebr., 5 (1906), pp. 128*).—Detailed statistical data of each county of the State covering such subjects as land values, crop production and values, shipment of various products, classifications of land and the areas thereof, census of fruits, population of towns, railway mileage, freight charges of the State in comparison with the rates in Illinois, Iowa, Missouri, and Kansas, etc. The value of products shipped in 1905, the bulk of which was of an agricultural nature, was $279,723,378.

Trade and agriculture of the Piræus and district for the year 1906, E. MACDONELL ET AL. (*Diplo. and Cons. Rpts. [London], Ann. Ser., 1907, No. 3785, pp. 33*).—In addition to statistics on the general trade relations of the Piræus for 1906, notes are given on the agricultural conditions of the district.

The peasantry of Greece are said to be remarkably poor though highly intelligent and industrious. The causes assigned for lack of progress in economic and social conditions are the want of police protection, the prevalence of malaria, the absence of agricultural banks, the lack of modern agricultural implements, and the neglect of proprietors and the government to provide for the drainage of land, the construction of roads, and the general encouragement of agriculture. Practically the only implements used in Greece are the plough, the hoe, and the reaping hook, except on the estate of the Lake Copias Company, on which modern machinery is employed. Most of this estate of 53,000 acres is worked by tenants on farms ranging from 2 to 100 acres in size, who pay a rent in kind of 20 per cent of the actual yield of produce. The wages of agricultural laborers range from £2 12s. to £3 7s. per month.

Tariffs on agricultural and animal products (*U. S. Dept. Com. and Labor, Bur. Manfr., Tariff Ser. No. 2, pp. 120*).—Tabulated schedules of tariff duties on agricultural and animal products imposed by the various countries in the world are reported.

AGRICULTURAL EDUCATION.

Report on agricultural instruction, 1904–6 (*Dept. Landb., Nijv. en Handel, Verslag en Meded. Dir. Landb., 1907, No. 1, pp. 204*).—This report contains detailed statements concerning the organization, faculty, courses of study, attendance, etc., of the agricultural institutions of different grades in the Netherlands. These include (1) the Royal Agricultural, Horticultural, and Forestry High School at Wageningen; (2) Royal Agricultural School, Royal Horticultural School, and Royal People's High School, at Wageningen, and Royal Dairy School at Bolsward; (3) royal agricultural and horticultural winter schools, and the communal agricultural winter school at Veendam, and (4) the Gerard Adrian van Swieten Horticultural School. The royal agricultural, horticultural, and people's high schools at Wageningen were formerly divisions of the Royal Agricultural School, but when, on September 1, 1904, the latter was enlarged, and became the Royal Agricultural, Horticultural, and Forestry High School, the three divisions mentioned became independent schools.

Reports are also given on itinerant courses in agriculture and horticulture, agricultural instruction for the army, work of agricultural, horticultural, and dairy instructors, courses in animal husbandry, horses and horseshoeing, the work of associations subsidized by the government, and an account of the agricultural instruction given in the armies of different countries.

Preliminary announcement concerning instruction in practical agriculture upon the university farm, Davisville, E. J. WICKSON (*California Sta. Circ. 29, pp. 8*).—This circular gives an account of the character of instruction on and equipment of the university farm, and an announcement and outlines of short courses for 1907–8.

Public industrial education, W. M. HAYS (*Amer. Mo. Rev. of Reviews, 35 (1907), No. 5, pp. 590, 591*).—This is a review of recent legislation for agricultural education and research (the Adams Act and the Nelson Amendment), and a discussion of the provisions of the pending Davis Bill to appropriate about $8,000,000 annually for industrial education in high schools of secondary grade.

Improvement of rural education in Great Britain (*County Council and Agr. Rec., 35 (1907), No. 846, pp. 132–134*).—The County Councils Association, at its meeting March 27, adopted a report of its rural education subcommittee dealing with the manner in which education in rural or agricultural subjects can best be fostered in the public elementary schools and evening schools in rural districts.

The report deals first with the nature of instruction in reading, writing, composition, arithmetic, nature study, drawing, and manual work, and maintains that all of these subjects should be taught with the idea of giving local application to the instruction. Reading, for example, should include considerable historical and geographical material of local interest. The composition should deal with nature-study work and manual training. Arithmetic should include the measurement of land, crops, stacks, cisterns, etc., the weighing of cereals and other crops, and problems in home accounts, marketing, profit and loss in the school garden, cost of cultivation, etc. Drawing should include freehand and color work with plants, as well as geometrical and scale drawing of fields, garden plats, buildings, boxes, and other objects. For the manual training work it is suggested that gardening be carried on for the purpose of studying the growth of crops in relation to the soil and to obtain skill in the operations of gardening, that there also be given opportunities for woodwork in making hencoops, garden frames, beehives, and other useful articles, and where possible, exercises in making baskets, nets, mats, etc. For the girls, needlework, cooking, household management, and elementary hygiene are recommended.

The committee emphasizes the importance of instruction in nature study and rural economy for all children, of school gardens in connection with elementary schools and continuation schools, of facilities for training teachers in rural subjects, of the organization of boys' agricultural clubs, gardening clubs, and junior naturalist societies corresponding to similar societies in this country, of making collections for school museums, and of organizing local fairs or exhibitions for the selection of appropriate material for larger agricultural shows.

Shall agriculture be taught in the secondary schools of the United States? S. A. KNAPP (*South. Ed. Rev., 4* (*1907*), *No. 1–2, pp. 53–64*).—A paper presented at the conference on secondary education in the South. Charlottesville, Va., November 22–24, 1906, in which a rather pessimistic view is taken of the possibilities for agricultural instruction in the public schools as at present organized. The speaker held that in these schools agriculture taught by the text-book method alone would be more injurious than beneficial, taught by object lessons solely the advantages would be very slight, but "taught by demonstration, each pupil being the demonstrator and working out the problems on a little farm under his exclusive control, rewarded by the success and the sale of the proceeds, would be of great value."

Agricultural education in secondary schools, W. LOCHHEAD (*South. Ed. Rev., 4* (*1907*), *No. 1–2, pp. 43–53*).—An address at the conference noted above, in which the agricultural work of secondary schools in Canada is described, with special reference to the Macdonald rural school movement.

Agriculture in high schools, D. J. CROSBY (*South. Ed. Rev., 4* (*1907*), *No. 1–2, pp. 37–43*).—A stenographic report of another address before the conference noted above. A description is given of some of the agricultural work now in progress in high schools, and sources of information and assistance for teachers are pointed out.

Pre-text-book work in agriculture for the common schools, M. A. BUSSEWITZ (*Wis. Jour. Ed., 39* (*1907*), *No. 4, pp. 142, 143*).—Suggestions for work in elementary agriculture in the years preceding the introduction of the text-book.

School training for the home duties of women. I, The teaching of domestic science in the United States of America. II, Belgium, Sweden, Norway, Denmark, Switzerland, and France (*Bd. Ed.* [*London*], *Spec. Rpts. Ed. Subjects, 15* (*1905*), *pp. 374+XV; 16* (*1906*), *pp. 352+XVI*).—Part 1 of this report includes an introduction devoted to the discussion of the scheme of public education in America, and the history and development of domestic science teaching. Following this are chapters devoted to the different phases of domestic science teaching in State institutions (primary and secondary schools, colleges, and normal schools), private institutions (elementary and secondary schools, institutions for training teachers in domestic science, technical institutes, women's colleges and universities), and social agencies engaged in promoting domestic science teaching (women's clubs, philanthropic agencies, summer schools, university extension, and the domestic service problem). Under each class of institutions there is a discussion of the kind of courses offered, such as cookery, needlework, hygiene, physiology, etc., and this is followed by brief outlines of typical courses in different schools. Eleven appendixes contain more detailed descriptions of some of the more important courses.

Part 2 consists of special articles describing the teaching of domestic science in the schools of Belgium, Sweden, Norway, Denmark, Switzerland, and France. This volume also contains tables of contents for the 15 preceding volumes of Special Reports on Educational Subjects.

Nature study as an education, Mary P. Anderson (*Nature-Study Rev., 3 (1907), No. 4, pp. 102–111*).—In this article the attitude of children toward nature-study material receives attention, and the value of nature study in developing the powers of reason and expression, in its esthetic and ethical relations to the pupils, and in affording information is discussed.

Nature study and school gardens, J. Craig (*Cornell Countryman, 4 (1907), No. 8, pp. 246–248, figs. 4*).—A brief description of the work in Canadian consolidated schools and groups of elementary schools.

The value of nature study and children's gardens, G. W. Carver (*Cornell Countryman, 4 (1907), No. 8, pp. 249, 250*).

Danish school gardens, C. Mariboe (*Haven, 7 (1907), Feb. 12, pp. 36–50, figs. 3*).—A report of the activities of the Skolehaven Society for the year 1905–6. An account of the history of the society is given, with brief illustrated descriptions of 17 different Danish school gardens.—F. W. Woll.

School gardens, P. Emerson (*New England Mag., n. ser., 36 (1907), No. 1, pp. 85–91*).—This is an account of the school garden work at the Cobbet School, Lynn, Mass., where much attention is given to a wild garden of native flowers and shrubs, gardens of cultivated plants, vegetable gardens, and cereal plats, all of which are closely related to the other school work. An effort is made to conduct the gardens on a self-supporting basis, and the way in which this is done is described.

The germination of garden and field seeds, V. H. Davis (*Agr. Col. Ext. Bul. [Ohio State Univ.], 2 (1907), No. 8, pp. 4–12, figs. 9*).—Suggestions for seed-testing exercises suitable for public school work.

An educational campaign in behalf of trees, O. J. Kern (*Forestry and Irrig., 13 (1907), No. 5, pp. 247–253, figs. 9*).—This is an account of the campaign conducted by the county superintendent of schools in Winnebago Co., Ill., during the years 1902–1906 to arouse an interest in tree planting and the decoration of school grounds.

Farmers' institute bulletin, 1906, E. R. Lloyd (*Mississippi Sta. Bul. 100, pp. 47, figs. 9*).—This bulletin contains addresses given at farmers' institutes in Mississippi and a list of regular institute workers.

MISCELLANEOUS.

Twenty-eighth Annual Report of North Carolina Station, 1905 (*North Carolina Sta. Rpt. 1905, pp. 84*).—This contains a financial statement for the fiscal year ended June 30, 1905, reports of the director and heads of departments on the work of the station during the year, and reprints of Bulletins 190–192. The report of the biological division is abstracted elsewhere in this issue (p. 150).

Twenty-ninth Annual Report of North Carolina Station, 1906 (*North Carolina Sta. Rpt. 1906, pp. 87*).—This report for 1906 is similar in form to that noted above. Bulletins 193 and 194 are reprinted. A portion of the report of the chemical division is abstracted elsewhere in this issue (p. 122).

Experiment Station Work, XLI (*U. S. Dept. Agr., Farmers' Bul. 296, pp. 32, figs. 4*).—This number contains articles on the following subjects: Wells and pure water, phosphates and soil acidity, pure seed v. poor seed, disease-resistant clover, eradication of wild mustard, sterilization of soils for preventing plant diseases, seedless tomatoes, pickling olives and mock olives, hay-box or fireless cooker, insect enemies of shade trees, feeding whole grain, improvement of cattle, ventilation of stables, hog cots, preserving eggs, and American Camembert cheese.

Development of New Caledonia, G. LAFFORGUE (*L'Elevage à la Nouvelle-Calédonie. Paris: Augustin Challamel, 1905, pp. 115, figs. 3, dgms. 2*).—The author has considered the climate and soil of New Caledonia at some length but has devoted the greater part of his monograph to a discussion of present conditions of cattle and sheep raising in New Caledonia and to the possible development of these branches of animal production.

Development of the Soudan, C. PIERRE and C. MONTEIL (*L'Elevage au Soudan. Paris: Augustin Challamel, 1905, pp. X+204, figs. 35, map 1*).—In this monograph on agricultural conditions in the Soudan the physiography of the country is considered, as well as its agricultural possibilities and present conditions. Chapters are devoted to horses, mules, and other farm animals, and to poultry, elephants, ostriches, camels, etc.

NOTES.

Alabama Canebrake Station.—J. M. Richeson has resigned as vice director and has been succeeded by F. D. Stevens, formerly of the Bureau of Soils of this Department.

Tuskegee Institute and Station.—H. G. Maxwell has resigned as dairyman.

Alaska Stations.—A station has been established near Fairbanks in the Tanana Valley on the tract of 1,400 acres reserved by Presidental proclamation for station purposes some time ago. During the summer the special agent in charge has cleared and broken ready for seeding next spring about 10 acres. A full equipment of farming implements, fencing material, seed grain, etc., has been provided, and a site selected for buildings. The location, soil, and exposure are deemed favorable to farming on an extended scale, but the plan is to clear the land as rapidly as funds will permit, operating the station along ordinary farm lines for several years in order to ascertain whether practical farming can be made successful in the region. Crops of all sorts, but more particularly grains and hay, will be grown and sold in the local markets. An account will be kept of both expenditures and receipts with a view to securing data as to profits. J. W. Neal, who carried on the work at the Copper Center Station for four years, will be in charge of the new station.

California University and Station.—Elwood Mead, professor of irrigation institutions and irrigation engineer, has been granted leave of absence until July 1, 1908, to take charge of irrigation work for the Australian government. M. E. Jaffa, of the department of nutrition and in charge of the poultry station, has been appointed director of the laboratory of the State board of health, but will retain his connection with the station work. R. H. Loughridge and G. E. Colby have returned from leave of absence in Europe. Recent appointments include W. T. Clarke as assistant professor of horticulture and superintendent of university extension in agriculture, C. Westergaard, recently of the North Dakota college, as instructor in farm mechanics, and G. W. Lyons as assistant in the division of soils in the station.

Connecticut College.—A short course in forestry is announced, to begin November 5 and continue six weeks, under the directorship of the State forester. The course will include the study of practical forest management, the reproduction, growth, and maturity of forest trees, destructive agencies in the forests and their control, and the care of Connecticut farm forests.

Connecticut State Station.—Recent changes in personnel include the resignation of Kate G. Barber, as microscopist, to accept a similar position with the Bureau of Chemistry of this Department, and the appointment of C. B. Morrison as chemist.

Delaware Station.—Miss Margaret B. McDonald, assistant chemist, has resigned to accept an instructorship in agricultural chemistry in the Pennsylvania College.

Indiana Station.—W. J. Jones, for a number of years chief deputy State chemist, has succeeded the director as State chemist and will have full charge of the feed stuffs and fertilizer inspection.

Iowa College.—Recent promotions include J. A. McLean and Wayne Dinsmore to associate professorships of animal husbandry, J. B. Davidson to a professorship of agricultural engineering, E. B. Watson to an assistant professorship of soils, and John Bower to an assistant professorship of dairying.

Kansas College and Station.—Osar Erf, professor of dairying, who has resigned to accept a similar position at Ohio State University. Other recent appointments include C. G. Elling, of the Cuban Experiment Station, as assistant in animal husbandry, E. G. Shafer in agronomy, and O. A. Stevens in botany. G. F. Freeman and G. C. Wheeler have been promoted, respectively, to assistant professorships of botany and animal husbandry. W. E. Mathewson, assistant chemist, has resigned to accept a position in the Bureau of Chemistry of this Department.

A six weeks' summer school in agriculture has been established, chiefly for teachers and similar in scope to that now given in domestic science. The veterinary science building provided for by the last legislature is in process of construction. A two-story stone structure, about 75 by 155 feet, with an auditorium annex 60 by 38 feet, is planned, to be completed by September, 1908, at a cost of about $70,000.

Kentucky Station.—E. C. Vaughn has been appointed assistant entomologist and botanist. A greenhouse to cost $10,000 is under construction.

Michigan Station.—Dr. Otto Rahn, of Halle, Germany, the author of several monographs on bacteriological subjects, has been added to the bacteriological division for work in dairy bacteriology, especially the relation of bacterial flora to the keeping qualities of milk and butter. Dr. G. A. Waterman has been succeeded as consulting veterinarian by Dr. L. M. Hurt, of the Iowa College. Dorothea Moxness, assistant chemist, has resigned to engage in commercial work.

Minnesota University.—Dr. Harold L. Lyon has resigned as assistant professor of botany to accept the assistant directorship of the pathological laboratory of the Hawaiian Sugar Planters' Station. Edward C. Johnson, assistant in botany, has been appointed assistant pathologist in this Department.

New Mexico College and Station.—Vincent B. May, of Las Cruces, has been appointed regent, vice José Lucero. Laurenz R. Greene, assistant in horticulture, has resigned to accept an assistantship at the Iowa College and is succeeded by A. D. Holloway, a graduate of the Kansas College. P. D. Southworth, assistant in animal husbandry, has resigned to enter commercial work, and S. B. Durham, a graduate of the Oklahoma College, has been appointed assistant in dairying. The live stock herd for instruction work has been materially increased. A course in farm machinery has been added, for which considerable equipment has been provided.

North Carolina College and Station.—A division of entomology has been established in charge of R. I. Smith, formerly State entomologist of Georgia.

Pennsylvania College and Station.—Hugh P. Baker, of the Iowa College and Station, has been elected professor of forestry, J. W. Clark instructor in poultry husbandry, W. H. Tomhave assistant in animal husbandry, W. R. White assistant in correspondence courses, and H. P. Fishburn assistant chemist. T. I. Mairs has been given charge of the correspondence courses. Since the beginning of the year five heads of departments and ten assistants have been added to the staff.

Rhode Island College and Station.—J. W. Bolte, assistant professor of animal husbandry and in charge of poultry feeding, has resigned to engage in commercial work. *Science* notes the appointment of Dr. L. J. Cole, chief of the investigations in animal breeding and pathology, as instructor in zoology in Yale University.

South Carolina College and Station.—R. W. Simpson, who has been president of the board of trustees since the establishment of the college, has resigned and is succeeded by Hon. Alan Johnstone. Other changes in personnel include the appointment of A. F. Conradi, of the Texas Station, as entomologist and zoologist in succession to C. E. Chambliss, whose resignation has been previously noted; M. R. Lowers, as veterinarian, in succession to L. A. Klein; and C. V. W. Cornell, as assistant chemist, in succession to W. E. Dickinson. H. D. House has resigned to take up work at the New York botanical garden.

Vermont Station.—Some investigations in the nutrition of young animals have recently been undertaken. A small building has been erected for the work.

Virginia College.—W. J. Quick has been elected dean of the college of agriculture and professor of agriculture.

Massachusetts Conference on Rural Progress.—In connection with the celebration of the fortieth anniversary of the opening of the Massachusetts Agricultural College to students, a four-day conference on rural progress was held October 2–5, 1907. Such interests as the State Board of Agriculture, the State Grange, the Massachusetts Civic League, the State executive committee of the Young Men's Christian Association, the Connecticut Valley Congregational Club, and the Western Massachusetts Library Association lent their active cooperation. The scope of the conference and the arrangement of topics are indicated in the partial summary which follows. The conference is also noted editorially in this issue.

The conference opened with an anniversary program, papers of a reminiscent and historical nature being delivered by Hon. M. F. Dickinson and W. H. Bowker, of the board of trustees. Director Brooks summarized the twenty-five years of experimental work at the college and outlined the function and aims of the station. At the afternoon session, C. L. Beach, of the Vermont University and Station, gave an address on Dairying, and N. J. Bachelder, master of the National Grange, spoke on The Grange and Rural Progress. The dedication of Clark Hall, the substantial botanical building in process of construction, followed, with addresses by Profs. D. P. Penhallow, of McGill University, and J. M. Tyler, of Amherst College, on the life and work of former President Clark, for whom the building was named. In the evening Dr. A. C. True, of this Office, spoke on The Broad Outlook of the Experiment Stations, and President Carroll D. Wright, of Clark College, on The Value of Art and Skill in Industry.

On the second day, State Forester Rane discussed The Forestry Situation in Massachusetts and Prof. John Craig, of Cornell University, Cooperation in Marketing Farm Products. The remainder of the day was devoted to a discussion of civic improvement, with addresses in the evening by J. R. Boardman, of the International Committee of the Young Men's Christian Association, on The Country Boy in Service, and by Henry Turner Bailey, of Worcester, on An Interpretation of the Civic Improvement Campaign in America.

The third day of the conference dealt especially with the rural library, church, and school, with an illustrated lecture by O. J. Kern, superintendent of schools of Winnebago County, Illinois, on The Front Line of Country School Improvement. Dr. G. E. Stone, of the college, discussed The Care of Shade Trees, and Prof. J. E. Rice, of Cornell University, Some Poultry Questions.

Saturday, the final day, was devoted largely to the interests of schools. The speakers included Mr. Kern on The New Agriculture in the Country School; Dr. K. C. Davis, of the St. Lawrence University School of Agriculture, on What Agricultural High Schools are Doing; Charles H. Morse, of the Massachusetts Commission on Industrial Education, on The Problem of Industrial Education; and George H. Martin, secretary of the State Board of Education, on Some English Experiments in Agricultural Education.

Kansas City Meeting of the American Veterinary Medical Association.—The forty-fourth annual meeting of this association was held in the New Casino in Kansas City, September 10–13, 1907. The attendance was larger than at any previous annual meeting and the interest shown by members and visitors was particularly gratifying. Among the special features was a visit to the Armour packing plant for the purpose of inspecting the methods of slaughtering and of curing and preserving meats, and for studying the unusually large and complete collection of pathological specimens taken during the regular routine of meat inspection by the agents of the Bureau of Animal Industry. On the last day of the meeting a clinic was held at the Kansas City Veterinary College, where a variety of surgical operations was performed.

As in previous years the various State secretaries made reports on the condition of veterinary practice in their respective districts and on the most prevalent outbreaks of animal diseases occurring during the year. A paper by A. Liautard directed attention to some of the difficulties at present encountered by the recent graduates of veterinary colleges. The necessity for uniformity in the requirements for matriculation, graduation, and curricula because of differences in the requirements of State examining boards was pointed out and it was urged that the veterinary schools should cooperate in establishing a standard of veterinary education. In a discussion of the paper Doctor Melvin justified the present Civil Service examinations and the six months' probation period in the appointment of inspectors.

D. A. Hughes discussed the place of veterinary medicine in State education. It was agreed that good veterinary courses should be established in all agricultural colleges. The importance of animal industry at the present time justifies the idea of providing proper instruction in each State for such students as may wish to become veterinarians. No veterinary school can be properly equipped and maintained without endowment, and this should preferably come from the State.

The present status of veterinary education in Europe was discussed at length by P. A. Fish, on the basis of observations made during a recent trip to some of the important European schools, particular attention being given to facilities and equipment of the veterinary schools of England, Scotland, Holland, Germany, Switzerland, and France.

A. H. Baker presented an account of intestinal obstruction in the horse. Acute cases rapidly prove fatal; subacute cases slowly recover or prove fatal in about two days. Acute cases may be due to an intestinal calculus, volvulus or intussusception. Subacute cases are caused by the formation of hair-balls, bots, parasitic worms, or tumors. Among the drugs which were found most successful in treating these cases mention was made of linseed oil, eserin, *Cannabis indica*, chloral hydrate, atropin, etc. Neither opium nor aloes should be used.

The effect of tuberculin upon milk production was discussed by S. H. Gilliland, who presented data of 500 nonreacting cows, the temperatures of which were taken following injection for four periods of twenty-four hours each. Although according to the averages of the four periods 58.6 per cent of the cows lost steadily, the loss was slight and may well have been due to other causes. Trials with 48 reacting cows showed, from 85.4 per cent, an average loss of 2½ pounds of milk daily, as compared with healthy cows. J. F. Winchester presented a historical account of the campaign since 1886 against tuberculosis in Massachusetts.

W. J. Taylor presented the results of a study of the agglutination test in glanders. At first the preparation of the test fluid gave much difficulty, but it was soon found that the agglutinating power may be preserved for a long time. The serum will keep from three weeks to three months if the blood clot is removed. Agglutination takes place at a much higher dilution than precipitation, and the method should properly be called a precipitation test, as it is not absolutely reliable unless precipitation takes place. The presence of mallein increases the amount of precipitin in the blood.

The general features of tumors were discussed by A. T. Kinsley and classified as to variations in structure, tissue, elements, size, form, and degeneration processes.

M. H. Reynolds read a paper on stable practices as affecting milk, mentioning a large number of outbreaks of typhoid fever, scarlet fever, diphtheria, and infantile diseases due to the milk supply. An outline was given of the results obtained at the experiment stations in the study of milk pollution from improper dairy practices. The municipal regulation of milk should include the establishment of standards of fat content, the exclusion of foreign material from milk, and the pasteurization of contaminated milk. It was urged that certified milk should not contain more than 10,000 bacteria per cubic centimeter, and that the dairyman's license should depend, more than is at present the case, on laboratory tests.

Municipal milk regulation in the South was discussed by C. A. Cary. Milk inspection is largely done there by graduates of agricultural colleges rather than veterinarians. It was urged that milk inspectors should be more familiar with practical dairying, as without this knowledge laboratory tests of inspectors are of little value. Tuberculosis is not greatly prevalent in the South, but many kinds of abnormal milk are observed. Injections of boric acid in the udder greatly reduce the number of leucocytes and streptococci in milk. In some cases it was found possible to obtain milk strictly free from bacteria and leucocytes.

G. A. Johnson discussed the relation of ventilation and disease. Strangles, tuberculosis, and various other diseases spread most rapidly in badly ventilated stables. Poor air predisposes animals to disease and the endurance of horses is lowered in close confinement. Artificial heat in stables was not considered necessary.

A. D. Melvin presented suggestions for work in the eradication of tuberculosis, which he declared to be steadily increasing in extent. If the loss from tuberculosis were made to fall on the owner of the diseased stock the disease would be more promptly eradicated. All cattle shipped for slaughter should be tagged to show their origin. Much worthless tuberculin has been used, but this product is now inspected by the Bureau of Animal Industry and when properly made is reliable.

Tuberculosis in swine, according to J. R. Mohler, is rapidly increasing and causes a greater loss than hog cholera. About 1.5 per cent of hogs shipped to slaughterhouses are affected with the disease and in Europe the percentage is often higher. In hogs the disease is generally acquired by ingestion, especially of raw milk and dairy by-products and the feces of tuberculous cattle. Hogs which do not follow cattle in the field and do not receive dairy by-products are only slightly affected. The disease is on the decline in Wisconsin on account of the general pasteurization of dairy by-products in the State. In experiments, feeding hogs tuberculous milk for three days produced a general infection, and 100 per cent of the hogs became infected after eating such milk for thirty days. Hogs are susceptible to human tuberculosis and may be infected from the offal about slaughterhouses. The cervical glands are most frequently affected, the disease resembling infantile tuberculosis rather than the bovine form. The desirability of cooperation betwen the Bureau of Animal Industry and State sanitary authorities in the eradication of the disease was pointed out.

W. L. Williams gave detailed clinical notes on twenty-two cases of roaring treated by surgical operation. Two of these were ruined by the operation, thirteen entirely recovered, and the others showed great improvement. The operation originally consisted in the removal of the vocal cords and the mucous membrane of the ventricle of the larynx, but better success has attended the less severe operation of the removal of merely the mucous membrane.

The officers chosen for the ensuing year were as follows: President, W. H. Dalrymple; secretary, R. P. Lyman; and treasurer, G. R. White.

Department of Agriculture of the Federated Malay States.—The laboratory and office building of the Department of Agriculture at the Rubber Experiment Plantations, Kuala Lumpur, is approaching completion. It is a two-story building 130 feet long, containing a capacious chemical laboratory and other laboratories for the director, the government mycologist, the entomologist, the superintendent and other scientific workers, as well as a library and offices. Dr. W. J. Gallagher, a graduate of the Royal University of Ireland, who has been engaged in research in natural history at Queen's College, has been appointed mycologist of the Department.

A New Demonstration Farm in Victoria.—The Minister of Agriculture, through the agency of the Lands Purchase and Management Board, has come into the possession of an estate of 540 acres at Wyuna, which will be devoted to demonstrations showing the profits to be made by working small areas under irrigation, especially in the production of forage and its utilization by cattle.

Tobacco Experiment Stations in South Africa.—Tobacco experiment stations have recently been established at Rustenburg, Barberton, and Pretoria. Selection and breeding experiments are being carried on and attention is also being given to problems of curing. At Rustenburg and Barberton curing and fermenting sheds have been erected.

School for Bee Culture.—The Association of Apiculturists of the Province of Schleswig-Holstein has located the first provincial school for bee culture in Prussia at Preetz, the city donating the site and making an appropriation of $2,380 to establish the school. The well-known apiculturist, Witt-Havetoft, was appointed director. The first course, for young men who wish to become professional apiculturists, will open March 1, 1908, and close December 1. Short courses of from 8 to 14 days for older apiculturists are also to be held during the year.

Miscellaneous.—The *Transvaal Agricultural Journal* notes the death on May 14 of Dr. Duncan Hutcheon, director of agriculture of Cape Colony. Preceding his appointment as director of agriculture Dr. Hutcheon had been chief veterinary surgeon of Cape Colony for 25 years.

Thomas Macfarlane, since 1886 chief analyst to the Inland Revenue of the Dominion of Canada, died suddenly of heart failure, at Ottawa, June 10. He was the author of a large number of reports and pamphlets dealing especially with the analysis and composition of Canadian food products.

We learn from *La Tribune Horticole* of the recent death of Étienne Griffon, director of the school of arboriculture and horticulture at Tournay.

Dr. Heinrich Hasselbring, assistant in botany in the University of Chicago, has been appointed assistant botanist at the Cuban Experiment Station.

It is proposed to celebrate the twenty-fifth anniversary of Roseworthy Agricultural College, the first of its kind in Australia, by the erection of a memorial to Ridley, the inventor of the Australian reaper.

Augustine Henry, of the Royal University of Ireland, has been appointed reader in forestry in Cambridge University.

O

EXPERIMENT STATION RECORD.

VOL. XIX. NOVEMBER, 1907. NO. 3.

The problems of organization and administration of station affairs become more difficult year by year as the activities and relations of the stations become more extensive and complicated. This seems inevitable, but it calls attention to the need of adjustment to the new conditions.

At one time a station council headed by a chairman was deemed sufficient to settle and manage the station business, or a college president through whose office the funds could be allotted and certain general business and correspondence conducted. We soon outgrew both of these arrangements, and have come to regard the station as a unit—not merely as an aggregation of separate departments grouped together for the purpose of sharing certain common funds. There are common aims and interests which bind the different departments together, and aside from this the station as a whole has certain outside relationships and responsibilities. These things have emphasized the need for a distinct organization and for a separate administrative officer. Effective organization has been one of the most important factors in developing the American stations and in giving them individuality.

While the desirability of a director and a certain degree of organization has become generally accepted, our conception of the duties of the director's office has not always kept pace with the growth in the station's activities and the responsibilities imposed. Coupled as these duties usually are with other services and reponsibilities, it becomes almost inevitable that some things should be left undone which ought to be done in the interest of good administration.

This is said in no spirit of criticism, but rather to call attention to several points which suggest themselves from a view of the field as a whole. The changing conditions of the stations incident to their development seem to make greater attention to these matters desirable at this time, as we are still to some degree in a condition of transition. What is said, therefore, is by way of suggestion, in an attempt to point out some general principles which should apply under the enlarged field of station activity.

The very diversity of the station work, with funds for research, for more general uses in agricultural experimentation, and often from the State for more popular features such as local or cooperative trials or demonstraions, imposes unusual duties on the administrative officer. It calls for careful study of the whole agricultural situation and needs with reference to the station work.

The new special fund for research work, although small at present, has added responsibilities and called more imperatively for careful planning. It has required relatively more attention than most of the funds because of the character of work provided for and the need of adjusting it to other activities of the station. It has necessitated more system. And when we add to the more strictly station work, the supervision of various kinds of police work, a variety of farmers' institute and extension work, the securing of new buildings and equipment, and frequently the supervision of the instruction in agriculture, it often occurs that the director's time is so divided that it is difficult for him to give adequate attention to the really legitimate station business.

Already many of the arguments forcefully used a few years ago against a college president as director are beginning to apply to the heads of some of our stations as their duties and offices are organized. These men are overburdened with a multitude of interests and duties, and this must inevitably be reflected in the details of their administration. They are attempting to do too much and are scattering their energies. Sometimes they are overestimating their capacity to do well a great variety of things, and in other instances conditions are imposed upon them which they are not able to remedy.

The direction of an experiment station is a business. Apart from the general oversight of the experiments and investigations it involves the judicious expenditure of considerable amounts of money, often under special limitations, and the orderly conduct of the affairs of the institution in a variety of directions. It calls not only for broad training and sympathies but for good administrative ability.

System and regularity are important factors in any scheme of administration. The lack of this adds greatly to the labors and anxieties, and prevents matters running smoothly in the station's internal and external relations. The difficulties might often be simplified by a closer organization of the station and a systematizing of its work. In a considerable number of instances our station management is suffering from too weak and loose an organization. There is a lack of sufficient system and formality in the planning and conduct of work and in the expenditure of funds, and a degree of independence of departments in their work and their interests which seems detrimental to the greatest economy and the highest efficiency.

While the greatest measure of freedom and individual initiative are desirable to the development of strong heads of departments, there are certain matters which pertain to good administration and which are essential to the proper conduct of the station business. The lack of closer organization and familiarity with one another's work hinders the development of the proper *esprit de corps*, and often prevents the coordination of the work of the different departments.

It seems desirable that the director should have more than a general knowledge of the work of his various departments. This is necessary for him to give it proper guidance and support and to hold it within the bounds agreed upon. Without some regular means of keeping in touch with what his men are doing he loses familiarity with it and with the course which it is taking. The outlining of projects to be filed in the director's office furnishes a means of following up the various lines of work and adjusting the expenditures. It also affords opportunity for coordinating the work of different departments and arranging for necessary cooperation.

It should also be one of the functions of the director to see that the work of different departments goes on in a regular way. It sometimes happens that work is sidetracked or dropped, or new lines substituted without the director's knowledge, and it is not infrequent to find men overburdening themselves with more experimental work than they can carry out to good purpose. Experience shows that a certain degree of regulation of the work as to amount and quality is quite essential. The amount undertaken is not always fully realized until it is outlined on paper, and this is one of the arguments for the submission of a programme of work or a list of projects.

The planning of the station's campaign and its policy requires increasing thought and study. The interests of different classes of constituents and the need for various grades of work must be considered, but in this the broader and more permanent needs of agriculture should be given full consideration. These need not be subordinated to the immediate queries of the farmers, for the two can often be harmonized and worked out together. The different phases of the work should be so organized as to offer the least possible disturbance and interruption to the working force, and plans must be laid for relieving the station proper of activities which do not strictly belong to it. Some of these still make quite heavy drains on the men's time. One of the most important functions of the director is to husband the resources and energies of his staff and to preserve an atmosphere congenial to their best work. This is not compatible with irregularity from day to day, frequent interruptions, change of work, indefinite policy, etc.

With so many station men occupying a dual position, and often with still other interests, a shifting of activities from one line of duty to another is a condition to be guarded against, for it brings great loss of efficiency and of interest in the work. Much can be done to minimize the necessity for this by systematizing the teaching, the institute work, and other duties, so that these will leave a greater amount of unbroken time. In a number of cases the conditions have been materially improved, and a general principle has been laid down which recognizes the need of continuity of effort, and the desirability of a separate staff for the more important departments.

There is still opportunity for improvement in the organization of the work with reference to inspection duties and their relation to other activities. The extent to which these interrupt more legitimate features of station work is often not realized. There is frequently some doubt as to how much of the time of the specialists is being absorbed or broken into by such work, and in some cases as to whether this service is being entirely supported by special funds. Its effect upon the men engaged in it is also an important consideration. As a matter of fact there are notable cases in which inspection work has been allowed to practically prevent competent station men from doing much else. The difficulty lies in improper organization or regulation of such work.

If the stations are to continue to exercise police control to an ever increasing extent over fertilizers, feeding stuffs, human foods, insecticides, milk-testing apparatus, nursery stock, seeds, etc., the organization of this work on such a basis that it will not interfere with or interrupt the legitimate functions of the station is a matter of much importance. Improperly organized and regulated, it becomes a serious drain on the efficiency of certain departments, which is not compensated for by the revenue it brings in. These matters may well receive more attention than is sometimes given them, for the scope and amount of this service has greatly increased in recent years. It should be adjusted to the other activities of the station, and considered in the light of its effect on general efficiency rather than the revenue it brings in.

The aversion to "red tape" has sometimes prevented discrimination between it and system. A certain amount of system and regularity in the business affairs of a station is essential to successful administration. It lightens the burden of the director and simplifies rather than complicates the duties of his office. The larger the institution the greater is its need, for the affairs soon get beyond the ability of one man to carry the details in his head.

While this applies to the supervision of both the work and the business of the station as a whole, its desirability is well illustrated in the expenditure of funds. The director can not shirk responsibility for the proper management of the station funds. Their supervision is one of his important functions. His general policy and knowledge of the needs of the work should guide him in the judicious use of these funds, and his system of purchasing and accounting should be such as to keep him fully informed as to their status and use. However much latitude he may allow in the purchase of materials after general lines of work have been agreed upon, he should at least know about important purchases of apparatus or equipment before the bills come to him for approval, and have opportunity to consider the wisdom of the purchases. He should also have sufficient data to intelligently classify the expenses among his various funds.

Without the exercise of supervision there will continue to be injudicious expenditures, unnecessary duplication of expensive apparatus which might be used by different departments in common, and considerable general confusion of funds which the accountant must untangle as best he can.

Lack of attention to the condition of accounts also allows large balances to accumulate toward the end of the year which, in the haste to save, often involve somewhat doubtful purchases. Proper planning and following up of the expenses would have resulted in more adequate and useful employment of the funds during the year. The Adams fund for the past year furnishes a number of illustrations of this kind, and emphasizes the need of following up the expenditures throughout the year and making prompt provision for using the increase of the following year. In some cases the delay in making provision for spending this fund was apparently due to untoward circumstances, but in others it was evidently due to lack of attention at the proper time.

The labor item is one likely to get beyond bounds unless there is systematic control and check upon it. Labor bills accumulate rapidly and become a large item in the monthly bills during the growing season. In some cases there is too much freedom and lack of control in this expenditure. The labor is not always suited to the special needs of the station, and the student labor especially is likely to be unprofitable. While considerable labor is indispensable to certain lines of station work, more careful planning of work at the outset and supervision of the labor expended upon it would often economize the funds spent in that direction. In cases where the experiment is on a commercial scale and yields considerable revenue the expense for labor might appropriately be charged to the sales fund rather than the Federal funds.

The preparation of bulletins and reports offers an opportunity for greater supervision, which will usually come through the director's office. The publication of bulletins without sufficient scrutiny as to fact or editorial supervision as to form and style is liable to bring embarrassment upon both the station and the writer. The investigator, from his very familiarity with the subject, is not always successful in putting his matter into the most intelligible form, and the general appearance of a bulletin counts for much. Frequently also the subject-matter laps over into the field of another department. The publications are an important product of the station's work. The effectiveness and the general impression of the station on the public are measured very largely by the clearness, accuracy, and general appearance of the material sent out. Nothing is lost by friendly criticism and suggestion, and the director may well provide some regular channel which will insure the manuscript being in creditable shape for publication before it goes to the printer.

Directors can not all be made in the same mold, and conditions are not alike at all institutions. But there are certain duties of administration which should be recognized in the efficient management of all station work and business. We have outgrown the simple methods which formerly sufficed. We need more formal and better systematized plans. The stations are growing and their relations becoming more and more involved. We must meet this by more effectual organization and administration.

The resignation of Dr. Elwood Mead from charge of the irrigation and drainage investigations of this Office closes a period of nine years of important service, which has been national in its scope and influence—a period of organization and rapid development in these two lines of agricultural engineering.

Doctor Mead has accepted the position of consulting engineer with a large company which is developing lands for irrigation near Denver under the reservoir system. Temporarily he has been released by that company in order that he might accept a short appointment under the Australian government for expert services in connection with the plans which are being laid for construction work. His intimate knowledge of irrigation laws and institutions, as well as the irrigation practice in different parts of the world, has made his services much sought for.

The funds for irrigation work grew out of a feeling that this Department should be giving attention to the peculiar problems arising under irrigated agriculture. These problems are as distinctly agricultural in character as are the improvement of plants or methods for their culture and utilization. They are concerned with the use of water in irrigation, and incidentally with whatever influences may affect that use. The drainage work has developed quite naturally out of and with the irrigation work, and has at present assumed practically equal proportions. From an initial appropriation of $10,000 in 1898, the fund for these two lines of work has grown to $150,000 for the present year. The work has proved very popular and has been in great demand, frequently in connection with large questions of interstate importance.

Following the withdrawal of Doctor Mead, it has seemed best to reorganize the work, recognizing more definitely the two different phases of irrigation and of drainage. Mr. C. G. Elliott, who has been the expert in the drainage work since it started, has been placed in charge of that branch; and Prof. Samuel Fortier, of the University of California, for several years at the head of the irrigation work which the Department has been doing in California, has been placed in charge of the irrigation branch. Both lines will remain under the supervision of this Office as before.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

On the atomic weight of nitrogen, D. Berthelot (*Compt. Rend. Acad. Sci. [Paris], 145 (1907), No. 1, pp. 65–67*).—The author gives figures for the atomic weight of nitrogen obtained by various methods, the average of which agrees almost exactly with the atomic weight reported in 1898, viz, 14.005.

Iodometric determination of ammonia, P. Artmann and A. Skrabal (*Ztschr. Analyt. Chem., 46 (1907), pp. 5–17; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 533, II, p. 196*).—In the method proposed an excess of sodium hypobromite of known strength is added to the ammonia or ammonium salt and the undecomposed hypobromite is determined in the usual way by adding potassium iodid and dilute sulphuric acid and titrating with standard thiosulphate, using starch as an indicator.

The recovery of albuminoid ammonia from distillates contaminated with permanganate, F. E. Hale (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 1085–1087*).—"The method, which is entirely of a chemical nature, consists in reducing the permanganate by an alkaline sulphite solution, oxidizing the manganous salt to the hydrated peroxid, filtering off the manganese on a carefully washed filter paper, nesslerizing the filtrate, and reading in the usual manner."

Separation of potassium from sodium as potassium platinum chlorid, J. Morozewicz (*Bul. Acad. Sci. Cracow, 1906, pp. 796–803; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 535, II, p. 396.*)—It is stated that since sodium platinum chlorid dissociates to some extent in absolute alcohol, forming sodium chlorid, which is practically insoluble in absolute alcohol, the weight of potassium platinum chlorid obtained by washing with the strong alcohol is found to be too large. Dissociation does not occur to an appreciable extent when 80 per cent alcohol is used, and correct results can, therefore, be obtained when this strength of alcohol is employed. Accurate results can be obtained with absolute alcohol if about 4 times the theoretical amount of acid platinum chlorid is used.

The determination of phosphoric acid in fertilizers, F. Mach (*Landw. Vers. Stat., 66 (1907), No. 1–2, pp. 1–62; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 535, II, p. 395; Chem. Abs., 1 (1907), No. 13, p. 1755*).—In this article comparisons of the Wagner, Neumann, von Lorenz, and German official methods for the citric acid soluble phosphoric acid in Thomas slag, and of the von Lorenz, Schenke, and citrate methods for total phosphoric acid in Thomas slag superphosphate and ammoniated superphosphate are reported, and the literature of investigations relating to various volumetric methods of determining phosphoric acid is very fully reviewed. There was close agreement in the case of citric acid soluble phosphoric acid in Thomas slag between the results obtained by the Wagner method and the official method with separation of silica, provided evaporation was not carried too far. In case of total phosphoric acid in Thomas slag the citrate and von Lorenz methods gave closely agreeing results, which were much lower than those yielded by the Schenke modification. The latter also gave decidedly higher results than the citrate method on superphosphates. The volumetric methods, of which the literature is critically reviewed, include the lead method of Schwarz, the alum method of Fleischer, the bismuth-nitrate method of Chancel, the silver method of Perrot, the uranium method of Le Conte and others, the molybdic method, and various titration methods.

The determination of the organic nitrogen in sewage by the Kjeldahl process. II, Studies of direct nesslerization, L. Whipple (*Technol. Quart., 20 (1907), No. 2, pp. 162–169*).—The Kjeldahl method, as used for the determination of organic nitrogen in sewage in the Massachusetts Institute of Technology, is described and tests of possible sources of error are reported.

One of the principal difficulties encountered in the use of the method is the turbidity of the digestate. Under ordinary conditions there is not sufficient calcium present in sewage to cause trouble from turbidity, but even small amounts of magnesium will render correct reading impossible. The latter, however, can be easily removed by adding an excess of 1½ per cent sodium hydroxid. The digestate is then filtered and directly nesslerized.

The analysis of silicate and carbonate rocks, W. F. Hillebrand (*U. S. Geol. Survey Bul. 305, pp. 200, figs. 24*).—This is a revision of Bulletin 176 of the Geological Survey (E. S. R., 12, p. 1006). The methods described are in the main those which have been perfected in the laboratory of the survey, but are not restricted to such methods. "A number of alternative ones are given which are known or believed to be good, in order that those who may wish to use this treatise as a practical guide shall have some choice of selection in case the expensive apparatus or complicated arrangements sometimes preferred are not available."

Precipitation and alkalimetric determination of silicon fluorid in the analysis of silicates, A. Hileman (*Ztschr. Anorgan. Chem., 51 (1906), pp. 158–170; abs. in Bul. Soc. Chim. France, 4. ser., 2 (1907), No. 11, p. 681*).—From comparative tests of various methods which have been proposed for this purpose, the author concludes that the Penfield and Bullnheimer methods give identical results and are more reliable than the other methods tested.

Determination of calcium carbonate in marl, M. J. van't Kruijs (*Chem. Weekbl., 4 (1907), pp. 29–32; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 533, II, pp. 197, 198*).—In the method recommended the sample of marl is reduced to a fine state of division by repeated grinding with successive small quantities of water, the fine powder in suspension being transferred to a Scheibler apparatus, and the carbon dioxid set free by addition of 30 per cent acetic acid. The reaction is considered complete in 1¼ to 1½ hours.

On the flocculation of clay emulsions, H. Hermann (*Ztschr. Anorgan. Chem., 53 (1907), No. 4, pp. 413–418, figs. 5*).—Observations on the effect of stirring and of the addition of different amounts of potassium nitrate are recorded.

A formaldehyde color test for proteids, I, S. F. Acree (*Amer. Chem. Jour., 37 (1907), No. 6, pp. 604–619*).—A preliminary account of a study of the importance of formaldehyde as a reagent for the detection of protein.

The author was led to undertake the work by the fact that when a small amount of casein or lactalbumin is mixed with a dilute formaldehyde solution and a small amount of concentrated sulphuric acid is added a violet zone is formed between the sulphuric acid and the solution. All of the proteids which the author has yet studied give the violet color when tested by this method, whereas, "in general, such substances as simple organic acids, sugars, alcohols, esters, amids, phenols, urazoles, semicarbazids, amino acids, polypeptids, and cyclic nitrogen compounds do not give the slightest color. In a few cases some violet color was developed, but in the check experiments without the formic aldehyde the same color exactly was shown; this was never the case with the proteids tested, and this fact enables us to distinguish the proteids from the nonproteids, so far as tested. In other words, the formic aldehyde reaction, as fas as tested, is much better than the biuret reaction, for it enables us to differentiate complex proteids from such compounds as polypeptids, uric acid derivatives and pyrimidins."

The author intends to continue his investigation, but "it can be stated now that a concentrated solution of formic aldehyde must not be used, and that one of the concentration 1 : 5000 is very satisfactory." Other aldehydes, ketones, etc., will be tested.

Rapid method for determining glucose with Fehling's solution, G. Lafon (*Compt. Rend. Soc Biol. [Paris], 62 (1907), No. 18, pp. 948–950*).—A modification of Bernard's method is described, which, according to the author, fits it for general use.

The value of different color reactions for identifying pentoses, F. Sachs (*Biochem. Ztschr., 1 (1906), No. 5–6, pp. 383–398*).—From a comparison of methods for clinical purposes the author concludes that though it has limitations the Neumann reaction is very satisfactory for diagnosing pentoses and preferable to the original orcin method or this method as modified by Bial.

Practical methods of detecting boric acid, J. Prescher (*Die praktischen Methoden der Bestimmung und des Nachweises der Borsäure. Lübeck: Charles Coleman, pp. 56, figs. 6*).—A summary and discussion of the detection of boric acid in the examination of feeding stuffs under the provisions of the German meat inspection law of June, 1900.

Examination and valuation of raspberry jam, E. Baier and P. Neumann (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 11, pp. 675–680*).—Raspberry jam contains on an average more material insoluble in water, than similar goods from other fruits, the values in jams examined ranging from 4.2 to 9 per cent. In the author's opinion, the ratio between water soluble material and sugar-free extract insoluble in water and between the alkalinity and the material insoluble in water are factors of decided value in judging of purity. A microscopical examination is also important.

Examination and valuation of ground black pepper, F. Härtel (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 11, pp. 665–675*).—The analytical data reported are discussed on the basis of judging the quality of pepper. When the crude fiber content is about 17 per cent the author believes that determinations of the glycogen value are desirable, as this factor is not so affected by drying. In general, the determination of both these values is to be recommended. The author regards 6.5 per cent as the maximum value for ash content. Appended to the article are a number of formulas for mixing pepper.

A new method for the determination of nicotine in tobacco, W. W. Garner (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 102, pp. 61–69*).—Six gm. of the pulverized air-dried material is treated with 3 to 5 cc. of a 5 per cent solution of sodium hydroxid and extracted for about 4 hours with 100 cc. of gasoline. Traces of ammonia are removed from 75 cc. of the filtrate by allowing it to stand for 1 hour, after which 10 cc. of fifth-normal sulphuric acid in 50 cc. of water is added and the mixture shaken in a separatory funnel. The aqueous layer is then drawn off and the gasoline washed twice with water. The excess of sulphuric acid is titrated with tenth-normal alkali, using cochineal as an indicator. One cc. of fifth-normal sulphuric acid is equivalent to 0.0324 gm. nicotine.

Apparatus for the supply of carbon dioxid in the determination of nitrogen in organic compounds by the absolute method, G. Young and B. Caud-

WELL (*Jour. Soc. Chem. Indus.*, *26* (*1907*), *No. 5*, *pp. 184, 185, fig. 1*).—A simplified form of Thiele's gas generating apparatus is described.

Apparatus for determining urea and total nitrogen, G. LAFON (*Compt. Rend. Soc. Biol.* [*Paris*], *62* (*1907*), *No. 17*, *pp. 899, 900, fig. 1*).—The instrument described is designed for use in determining urea and total nitrogen by the use of hypobromite. According to the author's investigations, accurate results can be obtained with it.

METEOROLOGY—WATER.

The progress of science as illustrated by the development of meteorology, C. ABBE (*Phil. Soc. Wash. Bul.*, *Vol. 15*, *pp. 27–56*).—The author traces the development of meteorology, particularly as indicated by the formation of national meteorological organizations and societies for research in meteorology, progress in the knowledge of elementary meteorology, and the constitution and properties of the atmosphere, and especially in recent contributions to the mechanics of the atmosphere by Bigelow and others.

New problems of the weather, W. L. MOORE, W. J. HUMPHREYS, and O. L. FASSIG (*U. S. Dept. Agr. Yearbook 1906*, *pp. 121–124*, *pls. 3*).—This article briefly describes the equipment at the Mount Weather Observatory of the Weather Bureau of this Department for the study of the upper atmosphere by means of kites or captive balloons, of the relation between sun and weather by means of the effect of solar radiation on terrestrial magnetism, and in experimental physics, the latter including spectroscopic investigations in cooperation with the University of Virginia.

It is explained that this observatory has been established for the promotion of "study and research leading to an increase in our knowledge of the laws governing the atmosphere such as should eventually enable our successors, if not ourselves, to add to the accuracy of weather forecasts and to make them for a longer period in advance," for it is realized that there is little hope of material improvement of practical forecasting "until a substantial addition is made to the pure science of the problem."

Cloud-bursts, so-called, E. L. WELLS (*U. S. Dept. Agr. Yearbook 1906*, *pp. 325–328*).—The author explains the popular use of the term "cloud-bursts," but states that "modern meteorologists have come to believe that in many instances at least the damaging floods occasioned by what are called cloudbursts are not so much a result of extraordinary and unexplained meteorological phenomena as they are the result of a topography favorable to a higher percentage of run-off, and a concentration of this run-off into a comparatively narrow and swift-moving stream."

The why of the weather, H. M. WATTS (*Jour. Franklin Inst.*, *164* (*1907*), *No. 1*, *pp. 43–46*).—This is an abstract of a paper illustrated with lantern slides in which the author developed "the general theory now held by leaders in the meteorological world as to the cause of variations in weather and climatic conditions."

Monthly Weather Review (*Mo. Weather Rev.*, *35* (*1907*), *Nos. 5*, *pp. 207–254*, *figs. 4*, *charts 9*; *6*, *pp. 255–302*, *figs. 5*, *charts 6*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of May and June, 1907, recent papers bearing on meteorology, recent additions to the Weather Bureau library, bibliographical notes, etc., these numbers contain the following articles and notes:

No. 5.—Biographic note on Dr. Alexander Buchan; Resolutions Adopted at the Milan Conference for Scientific Aeronautics, trans. by A. L. Rotch; Guilbert's Rules for Weather Prediction, by O. L. Fassig; Principles of Forecasting the Weather, by G. Guilbert; Observations of Halos at Columbia, Mo., by

G. Reeder; Observations of Halos and Coronas in England, by M. E. T. Gheury; The Relation of the Movements of the High Clouds to Cyclones in the West Indies (illus.), by J. T. Quin; Hailstorm at Corpus Christi, Texas, by J. L. Cline; Special Temperature Observations Made on Low Ground in the Vicinity of Vicksburg, Miss. (illus.), by W. S. Belden; The Philippine Weather Bureau; May Weather at Bangor, Maine; May—Past and Present, by E. D. Larned; Memorandum on the Gulf Stream and the Weather; Climate and Agriculture (outline of a course of lectures by T. L. Lyon, of Cornell University); Weather Bureau Men as Educators; The Cold Spring of 1907, by A. J. Henry; Barne's "Ice Formation with Special Reference to Anchor Ice and Frazil" (illus.), by W. W. Coblentz; Halos and Rain or Snow, by M. L. Dobler; Electric Storm in Southern California; Value of Weather Forecasts to Natural Gas Companies; and Meteorology in Australia.

No. 6.—Tornado at Wills Point, Texas, May 25, 1907 (illus.); Relations of the U. S. Weather Bureau to the Railroad Man; Legal Decisions as to Cyclones; Thunderstorms and Squalls; Climatology of Springfield, Mo., by N. R. Taylor; Hythers and the Comparison of Climates, by W. F. Tyler; An Old Indian Rule for Predicting Winter Temperatures; Hygiene and Climatology; Pale Green Sky Tints; Aerial Exploration Above the Ocean; Foehn in New South Wales; The Heaviest Local Rainfalls in California; Educational Notes (instruction in meteorology at Harvard); Dissemination of Useful Knowledge (through American research publications); Meteorological Terms Used in the Philippines; Weather Bureau Men as Educators; Confounding Cause and Effect (in case of temperature accompanying thunderstorms); The St. Swithin's Day Fallacy, by J. H. Morrison; The "Santa Ana" of California; Standard Time; Penalty for Counterfeiting Forecasts; Equinoctial Storms, by E. B. Garriott; Special Cloud Observation (illus.); Lenticular-Cumulus Clouds in Colorado (illus.), by J. B. Willsea; and Distinguished Cooperative Observers.

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Met. Buls. 223, 224, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1907. The data are briefly discussed in general notes on the weather of each month.

Meteorological report for the year ending December 31, 1905, F. SMITH (*Wyoming Sta. Rpt. 1906, pp. 57–62*).—The character of the meteorological equipment and of the observations made at the Wyoming Station is briefly explained and summaries are given of the temperature, pressure, precipitation, and wind movement during each month of 1905, and of the temperature and precipitation at Laramie for each year from 1891 to 1905. The maximum temperature recorded was 91° F., July 13, the minimum —42°, February 12, the mean 40.1°. The average barometric pressure was 23.069 in., the annual precipitation 9.76 in.

Swedish meteorological observations, 1906, H. E. HAMBERG (*Met. Iakttag. Sverige [Observ. Mét. Suéd.] K. Svenska Vetensk. Akad., 48 (1906), pp. X+157*).—This report is divided into 3 parts: (1) Daily observations at 18 stations of the second order, (2) monthly and annual summaries of all the meteorological elements furnished by 39 stations of the second order, and (3) 5-day means of temperature at the 39 stations included in part 2.

Rainfall observations (*Nedböriagttagelser i Norge, 12 (1906), pp. XX + 219, figs. 6, charts 2; abs. in Nature [London], 76 (1907), No. 1968, pp. 278, 279*).—This report summarizes observations at about 430 places during 1906, and includes means from 77 additional stations which have been discontinued. Daily observations on rainfall at 200 places and on snowfall at 50 places are recorded. Some of the yearly and monthly summaries go back as far as 1867.

Maps showing isohyets are given. These show a range of from 1,200 to 3,000 mm. on the west coast (latitude 59° to 62°) to 400 to 800 mm. yearly inland.

Science of the air with respect to ventilation, N. W. HOSKINS (*Tech. Lit., 2 (1907), No. 1, pp. 5, 6*).—The relation of the composition of the atmosphere to its sanitary condition is briefly discussed.

The atmosphere of towns, H. HENRIET (*Rev. Gén. Sci., 18 (1907), No. 5, pp. 183–190*); *abs. in Chem. Abs., 1 (1907), No. 14, p. 1886*).—The respects in which the air of cities and towns varies from that of the open country, the sources of contamination, and means of improving the air of urban districts are discussed.

The activity of air and spring water, F. HENRICH (*Ztschr. Electrochem., 13 (1907), No. 27, pp. 393–406*).—Investigations bearing on the radio-activity of air and water are reviewed.

Sanitary engineering with respect to water supply and sewage disposal, L. F. VERNON-HARCOURT (*New York, Bombay, and Calcutta: Longmans, Green & Co., 1907, pp. XXII + 419, figs. 287*).—The part of this book relating to water supply discusses ancient waterworks and available rainfall, sources of water supply, wells, lakes, and storage reservoirs, dams of various kinds and construction, intakes and conveyance and storage of supply, purification of water supplies, and distribution of water supply.

The second part, dealing with sewage disposal, discusses house drainage and disposal of refuse, sewerage, outfalls and clarification of sewage, utilization and purification of sewage on land, and chemical, electrolytic, and bacterial purification of sewage.

As regards sewage irrigation, it is pointed out that theoretically this is the proper use to be made of such waste products, but "so many difficulties surround the problem that the combined efforts of chemists and engineers have been unable in most instances to find a remunerative solution. . . . The great merit sewage irrigation possesses, as compared with discharging the sewage into a river or the sea, is that it utilizes the sewage to the utmost extent practicable, with great benefit to the land, and, under proper management, at a reasonable expense, and with efficient purification of the effluent." Previous clarification of sewage by septic tank or other forms of treatment promises to simplify the problem of sewage disposal by irrigation.

The value of pure water, G. C. WHIPPLE (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1907, pp. VIII + 84, dgm. 1*).—This is in the main a revision of a paper previously noted (E. S. R., 18, p. 314), which appeared originally in the series of scientific contributions, entitled "Biological Studies of the Pupils of William Thompson Sedgwick," with the addition of a few extracts from other lectures and addresses.

The author attempts from available data to establish formulas to be used in calculating the permissible depreciation due to sanitary quality, physical characteristics (color, odor, etc.), hardness, etc., of the water supply.

"The whole study is intended to illustrate a fact which in the past has been too little appreciated, namely, that an impure water supply affects not only the health and comfort of a community, but also the individual pocketbooks of the people."

State water survey of Illinois (*Engin. News, 57 (1907), No. 12, pp. 316, 317; abs. in Chem. Abs., 1 (1907), No. 12, pp. 1595, 1596*).—This article is based on the latest report of this survey, which has been in progress since 1895, the work being carried on through cooperation between the University of Illinois, the U. S. Geological Survey, and the State geological and water surveys. The report is divided into 4 parts: (1) Epidemics, (2) sewage purification, (3) water supplies, and (4) streams. A special feature is an account of a series of tests of septic tanks at Urbana.

SOILS—FERTILIZERS.

The use of soil surveys, J. A. Bonsteel (*U. S. Dept. Agr. Yearbook 1906, pp. 181–188*).—Attention is called to the vast extent and largely undeveloped state of the soil resources of the United States. The soil survey of the Bureau of Soils, in anticipation of the time "when the farm land now in use must be handled more intensively and more effectively and each acre must be made to produce to its maximum capacity the crops for which it is best fitted, . . . is examining into the total soil resources of the country and investigating the broad problems of the relationship of soil to crop."

The soil survey work began in 1899, and by June 30, 1906, a total area of 118,686 square miles, or 75,959,865 acres, in 43 States and 4 Territories, had been mapped. The surveys thus cover something less than one-tenth of the area actually in farms and about one-twenty-fifth of the entire area of the United States. "They have been so distributed as to constitute numerous studies of each important geographical and agricultural district. . . . The soil survey recognizes at present 13 great soil provinces, 58 soil series, and 461 soil types. Of these types some 130 are more or less local in character, while the remainder are of widespread occurrence within their respective provinces."

In making the surveys account is taken both of the character of the soil differences and the effects which they produce in the growing of farm crops.

"The individual report upon each soil-survey area contains an account of each soil type within the area. It gives a description of the characteristic appearance of the type and summarizes the crop uses to which it is put within the area. The methods of handling the soil are given, and a general statement is also made of the range of crop production. Such a report summarizes the actual uses of the soil within these restricted limits, and it also summarizes the farm practices in the given region. Each report also contains an account of the crops raised in other areas where the same type of soil has been encountered; and suggestions as to new crops, new methods of soil management, and new industries are made as a result of this wider knowledge secured from numerous surveys.

"From these reports on soil surveys the individual farmer may learn the relationships of the soils upon his own farm, not only to the other soils in the immediate neighborhood, but to soils of the same character in widely separated regions. He may thus observe and study understandingly the methods and results obtained under the most favorable conditions by successful farmers upon these soils."

The soil surveys also aid that large class of persons who for various reasons desire to secure new farms in more or less distant localities for the pursuit of general agriculture or for the production of special crops; large investment companies dealing in farm lands, and educational institutions engaged in the study and teaching of soil subjects.

No less important than these immediate and present uses will be the use of these surveys to supply future need for information regarding crop and soil adaptations which will result from increasing population, with greater intensity of cultivation, greater demands upon the soil, and greater precision and skill in the selection and handling of soils for special crops.

Reclamation of white-ash lands affected with alkali at Fresno, California, W. W. Mackie (*U. S. Dept. Agr., Bur. Soils Bul. 42, pp 47, figs. 2*).—This is an account of the work of the Bureau of Soils in reclaiming a tract of 20 acres of alkali land about 4½ miles southwest of Fresno by drainage and flooding. The work began in 1900 with a survey of the Fresno district, including the white-ash lands affected by the rise of alkali. The actual operation of flooding and drainage began in November, 1902, when a drainage system consisting of a main drain 2,010 ft. in length, and 9 laterals 3,650 ft. in length, was installed. The main drain emptied into a sump from which the drainage water was lifted by a pump.

"On account of the extreme height to which the ground water rises at certain seasons and of the difficulties previously experienced with hardpan and quicksand it was decided to place the tiles at an average depth of 3 ft. The water table each year rose much higher than this depth, and it was feared that the drainage system placed at a greater depth would be swamped by the rush of water from surrounding farms and would prove ineffectual. Six-inch tiles were secured for the mains, but a large number of 3-in. tiles had to be used in the laterals."

The results of the experiments extending over three seasons are summarized as follows:

"It has been found that alkali can be washed out of these white-ash soils, where no hardpan occurs close to the surface, during one irrigating season. It should then be fit to produce paying crops.

"The alkali at Fresno in the white-ash soils consists mainly of black alkali. To remove this alkali rapidly and effectively, it has been found necessary to hold water continually for several months over the soil at a depth of about 1 ft. When this is done, black alkali need not be feared.

"The amount of tiling necessary to drain these alkali lands for reclamation has been determined to be far less than formerly thought necessary. Natural stream channels and the great porosity of these soils made it possible to place drains several hundred feet apart, thus materially reducing the cost of reclamation.

"Efficient drainage systems, together with pumps of small capacity, have been found to remove easily and permanently a sufficient quantity of ground water to keep the water table below the danger limit throughout the irrigating season. These pumps may be readily driven by power furnished by water wheels in the canals. Cheap electricity also soon promises to be available for this purpose where water power is not to be had.

"When installing drainage systems, a competent engineer should be employed in order that the drains may be correctly laid on a proper and uniform grade. A contour survey of the surface of the land, together with one of the hardpan, is necessary to avoid the heavy cost of digging through hardpan and at the same time to secure the best drainage.

"In placing the tiles in the trench great care should be taken to crowd them closely together to exclude silt and sand. Silting is a serious problem in many alkali soils, but may be overcome readily by placing cables in the drains and drawing brushes through them.

"The time necessary to drive alkali out of the freer soils by continuous deep flooding may be as short as 6 weeks. Heavier soils require more time, but usually not more water.

"The practical trench test, to determine when the alkali has been sufficiently removed and when flooding should cease, should be used. A grain crop should follow during the next winter season. Any spots showing alkali can then be readily detected and treated in the following spring and summer.

"With the experience gained by the Bureau of Soils as a guide no insurmountable difficulty in freeing land from alkali should be encountered by farmers. The success attained in draining individual farms at the Toft-Hansen tract and other places clearly demonstrates that such drainage is a permanent and financial success. That such individual work will in time solve the problem of alkali reclamation seems highly probable."

Reclamation of alkali land in Salt Lake Valley, Utah, C. W. DORSEY (*U. S. Dept. Agr., Bur. Soils Bul. 43, pp. 28, pl. 1, figs. 2*).—This bulletin describes the Salt Lake Valley, its soil and alkali conditions, and the methods and results of reclamation work carried on by the Bureau of Soils and the Utah Experiment Station on a 40-acre tract in the valley since 1902. Previous work has been reported (E. S. R., 15, p. 859).

The contents of the bulletin are summarized as follows: "It has been shown that extensive tracts of land in Salt Lake Valley west of the Jordan River are not productive on account of alkali. On account of the nearness to excellent markets it is highly desirable that the farmer should know how to remove the alkali. Reclaiming alkali land to a limited extent has been practiced since the first settlement in the valley in 1847, but no extensive work has been undertaken by private enterprise. An experiment on 40 acres of worthless alkali land 4 miles west of Salt Lake City, conducted by the Bureau of Soils and the Utah Experiment Station, showed that such work is practicable, since the reclaimed land now supports a good stand of alfalfa. These results were accomplished by heavily flooding the land after a drainage system had been installed. It was found that surface flooding for one year leached away large quantities of alkali from heavy soils; in fact the quantity of alkali was so reduced that shallow-rooted crops could be grown the following year. The cost of reclaiming this tract of land is not large in comparison to the enhanced value of the land. . . . Much of the now idle land in Salt Lake Valley can be made to yield handsome returns by a limited outlay of time and money."

Excluding the cost of leveling, but including that of drainage, it is estimated that the alkali lands of this valley may be reclaimed at a cost of from $20 to $35 per acre.

Reclamation of alkali soils at Billings, Montana, C. W. DORSEY (*U. S. Dept. Agr., Bur. Soils Bul. 44, pp. 21, pl. 1, figs. 2*).—The soil and alkali conditions in the Yellowstone Valley and the methods and results of reclamation work commenced by the Bureau of Soils in 1898 (E. S. R., 10, p. 1026) are described.

It is stated that the soils of the Yellowstone Valley, in which Billings is situated, are largely heavy loams and clays which naturally contain large quantities of soluble salts, especially in the lower depths, derived from the shales and sandstones from which the soils of the valley have been formed. In the early development of the valley the areas visibly affected by alkali accumulations were small and attracted little attention, but with the extension of irrigation, involving as it often did the application of excessive amounts of irrigation water on heavy soils having very poor natural drainage, the damaged area has rapidly increased in size.

"An examination in 1898 by the Bureau of Soils showed that the deep subsoils were rich in salts, that shallow drains would be ineffectual, and that washing the surface only removed the accumulated alkali from a shallow depth of soil. . . . The experiment in reclaiming a worthless tract of alkali land by deep underdrainage and surafce flooding, conducted by the Bureau of Soils, proved successful, and after one year's treatment a good crop of oats was harvested. . . . At the present time the outlook in the valley is most promising, owing to the widespread interest manifested in the formation of drainage districts in the areas most severely damaged by excess of seepage waters and alkali."

The cost of drainage in these experiments was $35 per acre, but it is believed that with locally made tile and by excavating the trenches in the spring when the soil is more moist the cost need not exceed $15 to $20 per acre.

Texture of Massachusetts soils, G. E. STONE and N. F. MONAHAN (*Massachusetts Sta. Rpt. 1906, pp. 190–198, pl. 1*).—Mechanical analyses of typical soils from different parts of the State are reported and briefly discussed. The soils examined are classed as market-garden soils, cucumber soils, asparagus soils, tobacco and onion soils, rose soils, drumlin soils, and miscellaneous, including especially various samples from different parts of the experiment station farm.

Does the northern forest dry the soil? D. KRAVCHINSKII (*Lyesoprom. Vyestnik, 1906, No. 10; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 8 (1907), No. 1, pp. 72, 73*).—The author gives a table of determinations of moisture on meadow, pine woods, and fir woods down to a depth of 1 meter. The samples were taken once on August 9. Notwithstanding the fact that the meadow was found to be more moist than the pine woods by 2.5 per cent and than the fir woods by 5.85 per cent, the author arrives at the conclusion that it is not possible to say that the northern forest dries the soil, since it must be remembered that the crowns of the pines retain about 23 per cent and those of the firs up to 41 per cent of the amount of the precipitated rainfall.—P. FIREMAN.

Root action and bacteria, E. J. RUSSELL (*Nature* [*London*], *76* (*1907*), *No. 1964, p. 173*).—Experiments by the author and others are cited to show that heating the soil promotes the growth of many plants in a soil not deficient in calcium carbonate and increases the assimilation of organic and inorganic constituents. It is suggested that the injurious effect observed by Pickering (E. S. R., 19, p. 127) may be due to a deficiency of calcium carbonate in the heated soil.

Progress of the inoculation experiments, D. FINLAYSON (*Country Life* [*London*], *21* (*1907*), *No. 544, pp. 797–799, figs. 8*).—The beneficial effects in the early stages of growth of inoculation with Professor Bottomley's cultures for horse beans, alfalfa, sweet peas, and garden peas are noted and the influences of inoculation in increasing the nitrogen content of legumes, as well as the possibility of cross inoculations, are discussed.

On the question of nitrogen fixation in cultivated soils, F. LÖHNIS (*Mitt. Landw. Inst. Breslau, 4* (*1907*), *No. 1–2, pp. 39–46*).—This is a controversial article referring to previous articles by Pfeiffer (E. S. R., 16, p. 858; 18, p. 617).

The present status of the nitrogen problem, A. F. WOODS (*U. S. Dept. Agr. Yearbook 1906, pp. 125–136*).—This article reviews recent progress in investigations relating to the directly available nitrogen content of soils, the decay of organic matter, fixation of atmospheric nitrogen by soil bacteria, root-nodule bacteria, and the fixation of nitrogen from the atmosphere by electrical methods.

Special attention is given to methods of inoculation, and the conclusion is drawn that "pure-culture inoculation must eventually mainly replace the soil-transfer methods for all kinds of soil inoculation, but this has not yet been put on a practical basis for any except the nodule bacteria. The improved cultural and selection methods introduced by this Department in the practical handling of these forms have brought within reach of every farmer who may need them pure cultures of the most virile, vigorous, and best types of root-nodule bacteria for each particular leguminous crop. It requires care and skill, however, to make and keep these cultures in good condition. For lack of this, many who have tried to make these cultures have failed."

On the liming of beech moorland, P. E. MÜLLER and F. WEIS (*Naturw. Ztschr. Land. u. Forstw., 5* (*1907*), *Nos. 1, pp. 52–65; 3, pp. 154–170, figs. 2; 4, pp. 185–202, figs. 4; 5, pp. 225–249; Forstl. Forsögsv., 1* (*1906*), *No. 3; abs. in Skogsvårdsför. Tidskr., 5* (*1907*), *No. 1, pp. 27, 28*).—A series of experiments and observations is reported, which shows that liming of moor soils favors nitrification and the formation of nitrogen compounds which promote the growth of higher plants.

Losses in making and storing farmyard manure, T. B. Wood (*Jour. Agr. Sci., 2 (1907), No. 2, pp. 207–215; abs. in Chem. Abs., 1 (1907), No. 14, p. 1890*).—The character of these investigations and the results obtained are briefly stated as follows:

"Two pairs of young heifers were fed on a weighed and analyzed diet, and their dung was sampled and analyzed both in the fresh and in the rotted states.

"It was found that the fresh dung contained about three-fourths of the nitrogen, two-thirds of the phosphoric acid, and seven-eighths of the potash consumed by the animals in food and litter.

"The dung made by the cake-fed animals was found to be more readily fermentable, and consequently more liable to loss during storage, than that made by the animals fed on roots and hay only.

"The loss was found to fall chiefly on the ammoniacal nitrogen, in which the cake-made dung is comparatively very rich.

"Taking as a base line the amounts of nitrogen and phosphoric acid in the dung of the animals fed on roots and hay only, it was found that the fresh dung of the cake-fed animals contained 82 per cent of the nitrogen and 70 per cent of the phosphoric acid of the cake they had consumed.

"So great, however, was the loss of ammoniacal nitrogen from the cake-made dung that after 6 months' storage under cover in the solid undisturbed state in which it was left in the boxes by the animals only 37 per cent of the nitrogen of the cake still remained in the rotted dung.

"Dung is not usually kept so long as this, nor through such a hot time of the year, so that the average loss will probably be less than that found in the experiment, and one-half the nitrogen of purchased foods may very well be the average amount recovered in the dung.

"The experiment shows, however, that, without any very flagrant mismanagement, the proportion recovered may fall considerably below one-half, especially if the dung suffers further loss while lying on the surface of the land in dry weather."

Experiments in sampling liquid manure and observations as to conditions bearing upon the storage of liquid manure in cisterns, F. Hansen and R. K. Christensen (*Tidsskr. Landbr. Planteavl, 13 (1906), pp. 235–250*).—The results of analyses made by the authors show that liquid manure in cisterns should be sampled in different places below the surface, since the surface layer is likely to be too low in nitrogen through evaporation of ammonia. Satisfactory results are also obtained by analysis of a single sample taken half-way down the cistern, the error thus introduced being as a rule below 0.02 per cent nitrogen. Direct experiments in which liquid manure and solutions of ammonium carbonate or sulphate were kept in liquid tanks for 4 months showed losses through evaporation of ammonia of about 30 per cent of nitrogen in the case of the former two liquids and of 0.5 per cent in the case of ammonium sulphate.—F. W. WOLL.

Green manuring, A. Trunz (*Die Gründüngung, ihre technische Durchführung und wirtschaftliche Bedeutung nebst Beschreibung von Gründüngungswirtschaften. Berlin: Paul Parey, 1906, pp. IV+60; rev. in Ztschr. Landw. Versuchsw. Österr., 9 (1906), No. 12, p. 1069*).—This booklet discusses the nature and value of green manuring; various old and new systems of green manuring; the character, culture, and handling of various green manuring plants; and the value and adaptability of green manuring under various conditions and in connection with different systems of agriculture.

The suitability of the vegetation method for the determination of the fertilizer requirements of soils, V. Sazanov (*Zhur. Opuitn. Agron. (Russ. Jour.*

Expt. Landw.), 8 (1907), No. 2, pp. 129–146).—Pot and field experiments on this subject were conducted at the Ivanov Experiment Station during the years 1904, 1905, and 1906 on clayey chernozem soils with summer wheat and beets.

In the pots all soils showed a great need of nitrogen fertilizer, while in the field there was apparently little or no need of it. Two of the soils required no fertilizer whatever in the field, contrary to the indications of the pot experiments. The other two soils were very responsive in the field to phosphoric acid, which raised the yield very materially, while in the pots they were but slightly affected by this fertilizer. As to the potash, the results were similarly discordant. The author concludes that pot experiments are not suited to indicate the requirements of soils for fertilizers.

Experiments are reported in which oats were raised on the soil as soon as it was removed from the field to the pot and on the same soil which had been allowed to remain in the pot a year before the culture of oats was undertaken. In the first case nitrogen fertilizer was very beneficial, but in the second without effect. Analysis showed that by remaining a year in the pot the soil became greatly enriched in nitrogen, the original nitrogen content of 17.8 mg. rising to 43.5 mg. per kilogram of dry soil. There is no doubt that the result in pot experiments must depend to a great extent on the time of the year when the soil samples are taken from the field.—P. FIREMAN.

Report of cooperative fertilizer trials, 1906, P. BOLIN (*K. Landtbr. Akad. Handl. och Tidskr.*, *46* (*1907*), *Bihang*, *pp. 103*).—The cooperative fertilizer trials conducted under the auspices of the Royal Swedish Agricultural Academy were continued during the year, 198 different series with about 5,870 plats having been arranged for on 120 farms located in different parts of the country. Ninety-eight series of trials were conducted with spring grains, 75 with roots, 24 with hay crops, and 1 with winter grains. The results of the trials conducted during the year are given in detail in the report, with summaries for the years 1904–1906.

The following systems of fertilization produced the best financial results with the different crops on the average for the 3-year period: For oats, both on clayey and sandy soils 200 kg. of nitrate of soda and 300 kg. superphosphate per hectare; on peaty soils, 300 kg. of superphosphate and 100 kg. potash salt; for mangels, 100 kg. nitrate (top-dressing), 400 kg. superphosphate, and 250 to 300 kg. potash salt; for potatoes, 200 kg. nitrate, 300 kg. superphosphate, and 200 kg. potash salt. For hay crops the best system of fertilization varied according to whether grasses or clover made up the greater proportion of the hay; nitrate of soda produced, as a general rule, the best results for the grasses, and phosphate for hay composed largely of legumes. For mixed clover and timothy hay a complete fertilizer consisting of 200 kg. each of nitrate and potash salt and 300 kg. of superphosphate produced the best financial returns. The results obtained in the experiments show that the effect of a certain system of fertilization during the years following that of the application is often in a different direction from that indicated by the results of the first year. A decided after effect was noted, especially in the case of clover from potash-phosphate fertilization.

A separate series of fertilizer trials with different nitrogenous fertilizers—calcium cyanamid, lime niter, ammonium sulphate, and sodium nitrate—was conducted during the year, viz, 2 trials with oats on clayey soil, 1 with potatoes on sandy soil, 1 with fodder beets on clayey soil, 1 with mangels on sandy soil, and 3 with hay crops on clayey and sandy soils. The results of previous experiments with these fertilizing materials were in general corroborated in this year's work, showing that the two kinds of nitrate possess corresponding fertilizer values, and that the same holds true with calcium cyanamid and sulphate of ammonia when applied in quantities containing similar amounts of nitrogen.

Four series of experiments in subsoiling were conducted on clayey or humus soils, with vetches and oats, oats, and oats and barley. An increase in the yields of grain was obtained at harvest time from the subsoiled plats over those from the plats plowed in the ordinary way, ranging in the different series from 120 to 310 kg. per hectare, and from a loss of 10 kg. to a gain of 710 kg. in straw. There was an increase in the value of the crops harvested even in the first year, ranging from about 16 to 29 kroner per hectare ($1.75 to $5.36 per acre).—F. W. Woll.

Fertilizer experiments with precipitated calcium phosphate, III, H. G. Söderbaum (*K. Landtbr. Akad. Handl. och Tidskr., 46 (1907), No. 1, pp. 39–46*).—Precipitated calcium phosphate, prepared electrolytically according to the method of W. Palmaer, showed a fertilizing value similar to that of superphosphate in experiments conducted by the author during 1901–1905. It also resembles superphosphate in that liming has been found not to decrease its fertilizing effect, as is the case with tricalcium phosphate. The precipitated calcium phosphate contains 36 to 38 per cent of phosphoric acid, 95 per cent of which is citrate-soluble. The method of manufacture is described in the paper, with a brief account of pot experiments in which this fertilizer was compared with Thomas slag and superphosphate for oats.—F. W. Woll.

Can the availability of bone-meal phosphoric acid be increased by application of ammonium sulphate? O. Böttcher (*Landw. Vers. Stat., 65 (1907), No. 4–5, pp. 407–411; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 534, II, p. 295*).—In pot experiments ammonium sulphate considerably increased the availability of bone meal for oats growing in a humus sandy loam. This is attributed to the physiological acidity of the salt, as explained by Prianischnikov (E. S. R., 18, p. 539), for raw phosphate. Sodium nitrate had no such effect. It is questioned whether the small amount of ammonium sulphate ordinarily used in field experiments would give the results observed in the pot experiments.

Fermented bone meal was no more available than steamed bone meal.

Investigations on the action of heavy applications of ammonium sulphate in presence of organic substances and calcium carbonate in the soil, A. Stutzer (*Jour. Landw., 55 (1907), No. 1, pp. 81–91*).—Pot experiments with buckwheat followed by mustard to determine whether the injurious effect of adding organic matter (2 per cent of peat, 1 per cent of starch, and 1 per cent of chopped straw) can be prevented by adding sufficient ammonium sulphate to relieve the nitrogen hunger of the micro-organisms of the soil are reported, with incidental observations on the effect of calcium carbonate (1 per cent) under these conditions. In general the growth was poorer and the stands were less healthy with ammonium sulphate than with sodium nitrate. The addition of calcium carbonate increased the injurious effect of ammonium sulphate, both in soils which had received no addition of organic matter and those to which peat had been added. The addition of starch and chopped straw also depressed the yield. In case of the latter the injury was reduced by the addition of calcium carbonate. The addition of lime had a beneficial effect upon the following crop of mustard.

Comparative fertilizer trials with new nitrogenous fertilizers, S. Rhodin (*K. Landtbr. Akad. Handl. och Tidskr., 46 (1907), No. 1, pp. 3–21*).—The experiments here described were conducted at the experiment station at the Royal Swedish Agricultural Academy during the years 1903–1906.

The results of the trials are summarized by the author as follows: Calcium cyanamid applied directly before sowing time and harrowed in carefully and deeply did not increase the germination nor act injuriously on the young plantlets. Neither this fertilizer nor lime niter can be applied as a top-dressing to advantage, at least not for grass and potatoes. When so applied they have a strong burning effect, especially in dry, hot weather. The fertilizer value of cyanamid and ammonium sulphate for Swedish turnips, mangels, potatoes, and oats grown on clay land is fully equal to that of the sodium or calcium nitrates. The latter fertilizers are of similar value for oats. Late applications of cyanamid and ammonium sulphate greatly reduce their fertilizer value. The after-effect of the nitrogen remaining in the ground on the 2 following crops is most marked in the case of cyanamid. One kilo of nitrogen in sodium or calcium nitrate has nearly twice the value of a kilo of nitrogen in ammonium sulphate or cyanamid as fertilizers for sugar beets or fodder beets. Calcium nitrate has an excellent fertilizing effect, in most experiments even exceeding that of sodium nitrate.— F. W. WOLL.

New nitrogenous fertilizers, R. Guillin (*Bul. Soc. Agr. France, n. ser., 39 (1907), May 1, Sup., pp. 331–339*).—The manufacture and use of lime nitrogen and lime niter are briefly discussed and a number of practical experiments on different crops in France are reported.

Synthetic calcium nitrate, N. Passerini (*Rivista, 4. ser., 13 (1907), No. 10, pp. 226–229*).—An analysis of a commercial sample of lime niter is reported, showing about 13 per cent of total nitrogen and 25 per cent of calcium oxid. A very small proportion of the nitrogen was in nitrous form.

The products prepared from alkaline earth carbonates, charcoal, and nitrogen, O. Kühling (*Ber. Deut. Chem. Gesell., 40 (1907), p. 310; abs. in Chem. Ztg., 31 (1907), No. 30, Repert., p. 159*).—Studies of the amounts of alkali cyanids and cyanamids formed at 900 to 1,400° C., under different conditions, are reported.

The system, lime, nitric acid, and water, F. K. Cameron and W. O. Robinson (*Jour. Phys. Chem., 11 (1907), No. 4, pp. 273–278, figs. 2*).—The studies here reported of equilibrium in such a system were undertaken in view of the prominence which has recently been given to a mixture of lime and nitric acid ("lime niter"), as produced by the Birkeland and Eyde process.

The physiological action of dicyanamids with reference to their value as fertilizers, R. Perotti (*Centbl. Bakt. [etc.], 2. Abt., 18 (1907), p. 50; abs. in Chem. Ztg., 31 (1907), No. 32, Repert., p. 174*).—Solutions containing 2.5 parts of dicyanamid per 1,000 had no injurious effect. Such effect was observed only when the amount reached 3 to 4 parts per 1,000. Different plants varied in their power of resistance.

Storage of calcium cyanamid, H. von Feilitzen (*Chem. Ztg., 31 (1907), No. 30, p. 385; abs. in Jour. Soc. Chem. Indus., 26 (1907), No. 9, p. 478*).—It is shown that calcium cyanamid prepared by the Polzenius process contains a slight excess of calcium chlorid, which renders the product very hygroscopic, causing it to cake together in hard lumps and to burst the containing sacks. A considerable loss of nitrogen as ammonia (5 per cent or more of the total nitrogen) during 4 months was also observed.

The Stassfurt salt industry, W. C. Blasdale (*Chem. Engin., 5 (1907), p. 59; abs. in Chem. Abs., 1 (1907), No. 5, p. 628*).—The character of the deposits and the methods of manufacture at the new Stassfurt mines are described.

Cotton-seed meal as a fertilizer, E. H. Jenkins and J. P. Street (*Connecticut State Sta. Bul. 156, pp. 7*).—This bulletin briefly discusses the color, price, and nitrogen, phosphoric acid, and potash content of cotton-seed meal, as well as guaranties of composition and rebates which may fairly be claimed when the actual composition does not come up to the guaranty.

The valuation of ground fish (*Abs. in Saaten, Dünger u. Futtermarkt, 1907, No. 14, pp. 403, 404*).—The food and fertilizer value of this material, as based upon its content of fat, protein, and ash, is discussed.

Utilization of refuse liquid from beet sirup, L. KLEIN (*Pure Products, 3 (1907), No. 6, pp. 268-271, fig. 1*).—The process of drying this material and using it as fuel, with subsequent utilization as a fertilizer of the ashes obtained, are briefly described.

Analyses are reported which show that the original liquid contains about 2.8 per cent of ash, 0.3 per cent of nitrogen, 1.4 per cent of potash, and 0.03 per cent of phosphoric acid. The ash obtained from the material is reported to contain potassium carbonate about 42 per cent, sodium carbonate 12 per cent, potassium chlorid 12 per cent, potassium sulphate 8 per cent, potassium sulphite 2.8 per cent, and potassium phosphate 0.60 per cent. On storage the ashes decompose more thoroughly and the sulphite passes into other forms.

Report of the chemist—division of fertilizers and fertilizing materials, C. A. GOESSMANN (*Massachusetts Sta. Rpt. 1906, pp. 65-81*).—This includes reports on official inspection of commercial fertilizers and on general work in the chemical laboratory.

The results of examinations of 533 samples representing 354 brands are summarized. Tables show the average composition of the different classes of all fertilizer analyses, and the maximum, minimum, and average composition of special crop fertilizers. A schedule of trade values of fertilizing constituents and a list of licensed manufacturers and dealers are given.

Brief notes are also given on the examination of wood ashes and lime ashes.

Analyses of fertilizers, spring season 1907, B. W. KILGORE (*Bul. N. C. Bd. Agr., 28 (1907), No. 4, pp. 45*).—The results of the spring inspection and registration of fertilizers in North Carolina are reported, with brief explanatory notes.

Fertilizer analyses, fall season, 1906, and spring season, 1907, B. W. KILGORE (*Bul. N. C. Bd. Agr., 28 (1907), No. 7, pp. 79*).—The names and guaranteed composition of fertilizers registered for 1907, and analyses and valuations of about 700 samples of commercial fertilizers and 105 samples of cottonseed meal, examined during the fall of 1906 and spring of 1907, are reported, with explanations regarding terms used in fertilizer analyses, freight rates, valuation, etc.

Analyses of commercial fertilizers, M. B. HARDIN ET AL. (*South Carolina Sta. Bul. 126, pp. 40*).—This bulletin reports results of analyses of 744 samples of commercial fertilizers inspected under the State law during the season of 1906-7. The analyses are accompanied by notes on valuation, the composition of fertilizers and of the materials from which they are made, and the regulations controlling fertilizer inspection in the State.

The legal regulation of the fertilizer trade in Austria (*Österr. Forst u. Jagd Ztg., 25 (1907), No. 5, pp. 33, 34*).—The laws and regulations controlling this industry in Austria are briefly summarized.

AGRICULTURAL BOTANY.

Injury to vegetation and animal life by smelter fumes, J. K. HAYWOOD (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 998-1009*).—The author gives a summary of results of investigations carried on to determine the injury to vegetation by sulphur dioxid fumes near Redding, Cal., and around Ducktown, Tenn., and investigations to determine the injury to vegetation and animals by smelter wastes in the vicinity of Anaconda, Mont.

The investigations at Redding have already been noted (E. S. R., 16, p. 953).

In Tennessee the vegetation around the smelter appears from actual chemical analysis to be injured over a region approximately 20 miles long by 13 miles wide. There is little doubt but that the injury extends beyond the limits mentioned, but this can not be shown by chemical analysis, since the difference in sulphur trioxid observed in specimens of injured and uninjured trees becomes so small as to be within the results of experimental error.

The investigations in Montana were conducted to determine whether or not the vegetation is injured by reason of the sulphur dioxid set free by the smelters, whether or not enough arsenic is set free to settle on the surrounding vegetation and poison the forage plants so that they are unfit for cattle, and whether or not the waste discharged into the irrigation streams renders the water unfit for irrigation purposes.

In the first investigation it was found by careful examination that the forests were injured over a region at least 22 miles long and 15 or more miles wide. The injury to lodge-pole pines did not extend this far, but red fir was severely injured. An examination was made of leaves from injured and uninjured trees, and in 92 per cent of all the analyses the leaves from injured trees contained more sulphur trioxid than the uninjured ones.

As to the amount of arsenic given off by the smelter stacks, arsenic determinations were made of 20 samples of range grass, from which it appeared that 20 lbs. of the dried forage contained from 3 to 10.9 gm. of arsenic, the amount depending on the distance the samples were collected from the smelters.

From determinations of the effect of the waste from the smelters on the irrigation water, the author concludes that by reason of the large amount of copper discharged it is unfit for irrigation purposes.

In summarizing his observations the author states that the vegetation around the smelter for at least 7 to 8 miles south and 13 to 15 miles west was severely injured. Junipers are very resistant to smelter fumes and appear able to grow close to the smelter, red firs are very susceptible and were badly damaged at 13 to 15 miles from the smelter, while lodgepole pines appeared intermediate between the other two species, but showed some injuries for at least 10 miles. Large amounts of arsenic are discharged from the smelter on the surrounding country, being present in forage crops in large enough quantities to poison cattle. The waste from the reduction plant renders the water of the Deer Lodge River unfit for irrigation purposes.

An investigation of the injurious ingredients of smelter smoke, W. C. Ebaugh (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 951–970, pl. 1, fig. 1*).—An account is given of investigations carried on by the author to determine the effect of smelter smoke on the growth of plants. The investigations were conducted in Utah, and in addition to the observations made in the vicinity of smelters, experiments were carried on in fields to determine the effect of sulphur dioxid on beets and alfalfa.

In the experiments with alfalfa and beets different numbers of treatments with sulphur dioxid were given the plants, the amounts varying from 1 part to 10,000 parts of air to 1 part in 50,000. In another series of experiments sulphur dioxid in an aqueous solution was sprayed and poured over plants with injurious effect. The author then took up the action of flue dust on these same species of plants, and found in general that the appearance of the leaves of alfalfa and sugar beets was analogous to that produced when solid particles of flue dust were allowed to fall on the plants.

The author concludes that sulphur dioxid can not be considered harmless, especially in an inclosed space or in a moist climate, and that the harmful action of the solid emanations, called flue dust, from smelters has been underestimated.

Alkali studies, VI, H. G. Knight and R. B. Moudy (*Wyoming Sta. Rpt. 1906, pp. 45–51*).—In continuation of previous alkali studies, the investigations here reported were begun to determine what effect the presence of ions of different velocity had upon the absorption of salts by seeds and incidentally to determine whether ionic velocities had any marked effect upon salt absorption.

The authors, summarizing their report, conclude that in pure water seeds lose a portion of the salt. The absorption of salts by seeds is in direct ratio to the relative mobility of the ions. The addition of a more rapid ion, whether positive or negative, in small quantities to solutions of slower ions retards absorption of the slower ion. The experiments in which a slow positive calcium ion was added to rapidly moving ions were not very satisfactory, but the results indicate that the slow-moving calcium tends slightly to increase absorption.

The influence of magnesium sulphate on the growth of seedlings, Gertrude S. Burlingham (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 1095–1112, figs. 6*).—The investigations reported are the outgrowth of a comprehensive study of the nutrition of plants, the aim being to learn the effect of different mineral nutrients on the growth of a test plant and to note the variations produced by modifying the composition of the solutions. The test plant used was the common velvet weed, and the seedlings were transferred to water cultures in beakers containing various strengths of solutions based on the molecular weight of magnesium sulphate. In addition to the velvet weed, similar experiments were conducted with pea and maize seedlings.

The author gives the following summary of conclusions:

"Magnesium sulphate in solutions of greater concentrations than *m*/8192 has a toxic action on most seedlings, the degree of toxicity varying with the type of seedling and with the conditions. An *m*/8192 solution is toxic to pea seedlings, slightly stimulating to velvet weed, while it has a marked stimulating effect on corn seedlings. Maximum stimulation in magnesium sulphate results in solutions from *m*/32768 to *m*/131072, the point again varying according to the kind of seedlings grown. When magnesium sulphate is used in proper dilutions there may be produced a total growth nearly double that in the control; or in the case of velvet weed seedlings, a growth of the primary root 15 times that in the control. Not only is the growth of the primary root increased, but the lateral roots develop sooner, are more numerous, and attain a greater growth. Furthermore, the stimulation is lot limited to the root system, but the magnesium forces a more rapid and a greater growth of the hypocotyl and plumule. In these same concentrations, calcium nitrate causes very little stimulation.

"In addition to the marked stimulation which magnesium sulphate causes when it is used in dilutions from *m*/16384 to *m*/524288, it increases the vitality of the seedlings. The seedlings grown in the magnesium sulphate outlived those in the control by two or three weeks, and in some cases by a greater period.

"From the foregoing results and conclusions, it is then evident that magnesium sulphate, in the absence of other salts, is not necessarily injurious in its effects, but on the other hand may be highly beneficial; while any inhibitory action is due to the presence of a relatively large proportion of magnesium in the solution."

The presence of organic silica in plants, T. Takeuchi (*Bul. Col. Agr. Tokyo Imp. Univ., 7 (1907), No. 3, pp. 429–431*).—The author made a study of a number of species of plants to determine whether in plants or their products silica occurs in an organic form. The leaves of various species of grasses were subjected to analysis, and it was found that silica occurred in an organic form but that its quantity varied considerably. The exact nature of the organic silica compound was not determined.

The bacterial flora of the soil and its importance for agriculture, F. Weis (*Tidsskr. Landbr. Planteavl, 12 (1905), pp. 130–179*).—A comprehensive discussion of our present knowledge of the subject.—F. W. WOLL.

Relation of plant growth to root space, S. Kumakiri (*Bul. Col. Agr. Tokyo Imp. Univ., 7 (1907), No. 3, pp. 437–439*).—On account of the observed fact that many plants yield smaller returns when grown in small pots than when grown in large ones, the author conducted a series of experiments with spinach and barley to determine the effect of the size of pots on plant production. The same kind of soil was used in each instance, the smaller pots holding 2 kg., while the larger ones were of 10 kg. capacity.

The plants were measured and weighed, and an examination of the roots in both cases revealed great differences, the roots in the small pots growing along the wall of the pots more than in the case of the larger ones. In the large pots the plants flowered and ripened earlier than in the smaller ones, and with barley the total yield in the large pots was 4.8 times that of the small ones, while with the spinach the yield in the large pots was 2.5 times that of the small pots.

The production of races of cultivated plants inured to drought. I, Anatomical-physiological investigations, V. Kolkunov (*Izv. Kiev. Politekh. Inst., 1905, p. 82; abs. in Zhur. Opuitn. Agron. (Russ. Jour. Expt. Landw.), 7 (1906), No. 6, p. 709*).—This article is a part of the extended investigation undertaken by the author with the object of producing by selection races of cultivated plants which, utilizing the soil humidity most economically, will endure drought.

After a review of the literature concerning the protection of plants against excessive evaporation the author arrives at the conclusion that all the available data are not sufficient to explain why two races of wheat very similar in anatomical structure may differ in the magnitude of their evaporation. By means of careful measurements the author succeeded in establishing the fact that varieties of wheat and other cereals with different xerophytic properties do not differ from one another by the presence of special protecting tissues or the arrangement of their tissues, but only by the magnitude of the anatomical elements of their leaves. Moreover, it was found that the change of the magnitude of the stomata always goes parallel with the changes of the other elements, and hence it is sufficient to confine oneself to the measurement of the variations in the magnitude of some one element. As such a fundamental measure, the author accepts the length of the stomata.

The author also takes up the question as to what determines the degree of the xerophytic property of a plant—the development of its root system, as many investigators believe, or the magnitude of its evaporation. On measuring the magnitude of evaporation in plants with different xerophytic properties, the author concludes that there is a complete correspondence between the xerophytic properties of a plant and its evaporation.

From these preliminary experiments it is clear that there must exist a close connection between the magnitude of evaporation and the size of the stomata. This conclusion is corroborated by a whole series of experiments and measurements made of different varieties of wheat and other gramineous plants. It was found that the larger the stomata the more humidity the plant evaporates and the lower its xerophytic capacity. Guided by these conclusions the author succeeded in obtaining by means of selection during 4 years a race of wheat with a greater xerophytic capacity.—P. FIREMAN.

FIELD CROPS.

Report of the agriculturist, W. P. Brooks, E. S. Fulton, and E. F. Gaskill (*Massachusetts Sta. Rpt. 1906, pp. 23–60*).—The experiments here reported are in continuation of earlier work (E. S. R., 18, p. 226). This year the experiments included 308 field plats, 150 closed plats, and 286 pots in vegetation experiments.

In 1906 corn was grown in the experiment comparing different sources of nitrogen. According to the results of this year the materials ranked as follows: Barnyard manure, nitrate of soda, sulphate of ammonia, and dried blood. Based on the increase of all the crops since the beginning of the trials in 1890 the relative rank on a percentage basis was nitrate of soda 100, barnyard manure 85.31, dried blood 70.06, and sulphate of ammonia 63.54.

High-grade sulphate of potash was superior to muriate for soy beans, rhubarb, raspberries, blackberries, potatoes, and mixed hay. The muriate gave the larger crop of asparagus. In connection with determining the relative value of different potash salts for field crops potatoes were grown this year and the salts, based on the average of 5 trials for each, ranked as follows: Muriate, low-grade sulphate, high-grade sulphate, nitrate, carbonate, kainit, and silicate. The use of potash as a fertilizer seemed to reduce susceptibility to early blight.

A heavy application of manure alone gave slightly larger yields of mixed hay at the first and second cuttings than a combination of a smaller amount of manure and potash. During the 16 years this experiment has been in progress the average yields of 10 crops of corn and 6 of hay have been greater on the larger amount of manure alone but not sufficiently greater to cover the extra outlay at a cost of $5 per cord for the manure.

In connection with the comparison of different phosphates mixed hay was grown. The yields varied but little, showing that the hay crop is much less dependent upon the quantity of available phosphoric acid applied than the crucifers, such as cabbages and turnips, as indicated by previous results. The results of the soil tests indicated that the hay crop requires a supply of nitrogen in a highly available form. In the test in which barnyard manure, wood ashes, and a combination of fine ground bone and potash was applied in rotation for the production of grass, the average yield of hay in 1906 was 4,002 lbs. per acre. The average for the 14 years the test has continued is 6,389 lbs.

Winter application of manure on a slope resulted in a small loss of fertilizer value as compared with spring application, but the gain in crop was not sufficient to pay for the extra cost in applying it in the spring.

The use of nitrate of soda for rowen gave a profitable increase in crop this year, but the results in the different years the test has continued show a wide variation with the amount of rainfall during the growing season.

In a comparison of 25 varieties of potatoes, Climax, Chenango White, Hammond Wonderful, and Simmon Model ranked first in productiveness, with yields in excess of 200 bu. of merchantable tubers per acre.

The Woburn field experiments, 1905 and 1906, J. A. Voelcker (*Jour. Roy. Agr. Soc. England, 67 (1906), pp. 282–310*).—These experiments have been described in earlier reports, and former results have also been previously noted (E. S. R., 18, p. 28).

In 1905, in the continuous wheat-growing experiments, the unmanured plats yielded 14.25 bu. per acre. The highest yield, 32.45 bu., was secured on the plats receiving barnyard manure each year. The largest crop obtained with commercial fertilizers was 26.57 bu. per acre. Ammonia salts alone gave no crop worth reaping, while the plat receiving 2 tons of lime per acre in 1897 yielded 10.2 bu. per acre, or as much as was secured from the use of nitrate of soda alone. The nitrate of soda plat is undergoing a gradual diminution in yield. Ammonia salts applied with mineral manures gave a higher yield than nitrate of soda, but when the heavier dressings of the salts were used the ammonia salts showed the same signs of failure as they did when applied alone and in quantities furnishing 50 lbs. of ammonia per acre.

The rape cake plat did not give as good yield as the barnyard manure plat. Ten cwt. of lime per acre gave a good increase in yield, while 5 cwt. effected no change, and applications of 1 and 2 tons per acre seemed to retard the crop.

In 1906, the rape cake plat yielded 34.5 bu. per acre, as compared with 16.2 bu. for the barnyard manure plat. Rust was most marked on the nitrate of soda plats. The unmanured plat yielded 11.5 bu. per acre, and the plat receiving nitrate of soda with minerals produced 35.2 bu., the highest yield secured. The plat receiving ammonia salts and minerals, including 10 cwt. of lime, gave a yield of 34.7 bu. per acre. Ammonia salts alone, in quantities furnishing 50 lbs. of ammonia per acre, produced only 3.5 bu. per acre, as compared with 26.1 bu. for the plat receiving 2 tons of lime in 1897. The results of this year also indicated that the influence of a dressing of 2 tons of lime per acre will last with cereals for at least 9 years.

In both years the crop grown with nitrate of soda was characterized by a large quantity of screenings and a low bushel weight. Rape cake and ammonia salts with lime gave the best weight per bushel, lime seeming generally to be beneficial in this respect.

In 1905, in the barley-growing tests, the unmanured plat yielded 19.35 bu. per acre, while barnyard manure produced 42.6 bu., and a dressing of minerals, ammonia salts, and lime 40.6 bu. Mineral manures alone gave 23.3 bu. per acre, while ammonia salts alone gave no crop, and ammonia salts with lime but no minerals 23.7 bu. per acre. Nitrate of soda with minerals gave a yield of 30 bu., while ammonia salts with minerals and lime gave 40.6 bu. With rape cake, a yield of 34 bu. was secured. Barnyard manure excelled in yield and quality, while nitrate of soda produced the poorest quality of grain.

In 1906 the crop of barley was a distinctly heavy one, the unmanured plat yielding 15 bu., the plat receiving minerals alone 18.8 bu., barnyard manure 45.6 bu., rape cake 45.8 bu., nitrate of soda and minerals 47.5 bu., and ammonia salts with minerals, including lime, 44.3 bu. per acre. Nitrate of soda alone gave a yield of 36.3 bu., and a heavy dressing of this substance with minerals 60.8 bu. of grain and 42 cwt. of straw per acre. In the case of barley, the continuous use of nitrate of soda has apparently not been detrimental. The plats receiving ammonia salts alone, or ammonia salts and minerals without lime, gave practically no crop at all, but where 5 cwt. of lime were given, 11.6 bu., where 1 ton was used, 33.9 bu., and where 2 tons were applied last in 1897 to 2 different plats, 25.4 bu. and 44.3 bu. were secured. The further use of 2 tons of lime in 1905 resulted in an additional increase of 13 bu., though no minerals had been put on. Nitrate of soda reduced the quality slightly this season. The best weights per bushel were obtained from the barnyard manure plat and the plats fertilized with ammonia salts and minerals, including lime.

In a rotation experiment, sheep were fed per acre 12 tons of swedes, 4½ cwt. of clover hay chaff, and 920 lbs. of decorticated cotton cake, or the same quantity of maize meal. The test was conducted on 4 plats, on the first of which the swedes were fed off with decorticated cotton cake, on the second with maize meal, and on the other 2 without cake or corn. The first plat produced 8 bu. more barley and 7 cwt. more straw than the second plat, which yielded practically as much grain as plat 3, but 2 cwt. more straw per acre.

In another rotation test, in which kohl-rabi were grown instead of swedes, the decorticated cotton cake plat produced 6.4 bu more than the check plats.

while the maize meal plat produced 0.2 of a bushel less. After the barley was harvested 2 tons of lime were applied per acre and the land sown to white mustard on June 14, 1906. The heaviest yield was secured on the maize meal plat, but the yields on 3 of the plats did not show very great differences.

A green manuring experiment was conducted on Lansome field in 1905 and 1906 with tares and mustard, treated with mineral manures and lime. The tares in each case gave the heaviest yield, and when plowed under added more than twice as much nitrogen as the mustard. The following season, however, the best yields of wheat were secured on the mustard plats. Results secured in 1905 with different grades of barley seed indicated that the selection of large plump grains, or the rejection of the smaller grains, is not necessarily advisable for seed purposes.

Comparative tests of native and English wheat were made in 1905 and 1906, with the result that the English wheat, Square Head Master, in each case gave the higher yield of grain and straw. Canadian Red Fife outranked the English variety in quality, but the much higher production of the English wheat made it the more remunerative. Soot used as a top-dressing for wheat was analyzed and found to contain 4.56 per cent of nitrogen. It was applied at the rates of 40 and 20 bu. per acre. The use of 20 bu gave a slightly heavier yield than the use of 1.5 cwt. of nitrate of soda, and even the use of 40 bu. gave a profitable increase.

Fertilizer experiments with potatoes indicate that on light land 1 cwt. per acre of sulphate of potash is a better dressing than 4 cwt. of kainit, the 2 supplying practically equal quantities of potash. The best total yield of tubers was secured where 3 cwt. of superphosphate, 1 cwt. of sulphate of ammonia, and 1 cwt. of sulphate of potash were used.

The results of fertilizer experiments with mangels in 1905 and 1906 show considerable gains from the use of top-dressings with nitrate of soda and salt over barnyard manure alone. The use of 2 cwt. of nitrate of soda per acre gave a smaller crop than the use of 1 cwt. The best return in each year was obtained with the mixture of 1 cwt. of nitrate of soda and 1 cwt. of salt, and the next best from using 1 cwt. of soda alone. It was also found that mangels taken up at the usual time, about October 10, gave a smaller yield than mangels allowed to remain in the ground until the first frost, which this season was on November 12. The chemical composition of the 2 lots of roots did not show very great differences.

The best fertilizer applications for alfalfa in 1905 and 1906, the fourth and fifth years of the test, were 4 cwt. each of superphosphate, bone dust, and sulphate of potash, supplemented by 2 cwt. of nitrate of soda or sulphate of ammonia. A test of Provence, South American, and Canadian alfalfa seed resulted in favor of the Canadian. Of different varieties of clover tested, English late-flowering red gave the largest first cutting, while the second cutting was very small. The highest yield was obtained from the English red, although Chilean, Canadian red, and Canadian mammoth red gave yields almost as good. Silesian clover gave much the lowest yield.

Diversified farming under the plantation system, D. A. BRODIE and C. K. MCCLELLAND (*U. S. Dept. Agr., Farmers' Bul. 299, pp. 14*).—The need of crop diversification is discussed and an experiment in diversified farming is described. Tenants on the Rosalie plantation at Moreland, La., were induced to set aside for the experiment nearly 2 acres of land, on which were planted potatoes, watermelons, sweet corn, and cabbage. Poor seed and dry weather were most unfavorable to the corn and cabbage crops. Excluding one failure the net profits per acre with potatoes varied from $10.58 to $61.49. The yields varied from about 8 to 107 bu. per acre, averaging 61¼ bu. The potatoes were dug May 21 and 22 and sold at 90 cts. per bushel. "In addition to this crop of potatoes with profits of over $30 per acre it would have been possible to have grown afterwards a good crop of Mexican June corn or cowpeas, or other crops upon this same land and to have followed these by some winter crop."

The watermelon yields varied from 0 to 600 melons per acre, or about 300 per acre for the 15 productive plats recorded. The financial results varied from a loss of $4.54 on half an acre to a gain of $85.83 per acre, with an average profit of $25.41.

The results of this first year's work lead to the conclusion that it is possible to establish a system of diversification of advantage to the tenant and the planter.

A successful dairy farm, L. G. Dodge (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 102, pp. 19–23, pl. 1*).—The system of management on this farm was studied and is reported in this bulletin. The different points discussed are the rotation followed, the harvesting of the hay, feed for cows and calves, butter production, poultry production, and the results achieved. Half the land of this farm is in permanent pasture and the rest nearly all permanent meadow. A few acres of meadow are broken up each year and sown to peas and oats with grasses and clovers, or planted to corn for soiling which is to be followed by peas and oats, grasses and clovers. The object of the bulletin is to explain a method of managing permanent grass land to maintain its productivity.

Planning a cropping system, W. J. Spillman (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 102, pp. 25–31, figs. 2*).—The value of a definite cropping system for farms is discussed, and the farm selected to illustrate the methods used for this purpose is described.

In studying the requirements of this particular farm, it was found that 17.03 acres of corn, 45 of hay, 40 of pasture, and 0.52 of rape, or a total of 102.55 acres, would furnish the proper amounts of forage for the stock. The farm in question contains 103 acres of arable land and 11.77 acres of woodland pasture. It is pointed out that 25 acres of pasture for cows and 5 acres of clover pasture for hogs are required. The woodland pasture is considered as sufficient for the young stock raised on the farm.

A consideration of the conditions specified led to the adoption of one 3-year rotation as follows: First year, 7 acres of corn and 18 acres of peas and oats; second year, timothy and clover; third year, timothy and clover. A second 3-year rotation was arranged as follows: First year, corn in which clover is sown in the last cultivation; second year, clover; third year, peas and oats for hay, followed by rape sown in midsummer. A 2-year rotation was also laid out for two 5-acre fields of corn followed by fall-sown rye the first year, and rye followed by soy beans the second year.

The first 3-year rotation provides for the 25 acres of cow pasture, the second for the 5 acres of clover pasture for hogs.

The application of vegetative propagation to leguminous forage plants, J. M. Westgate and G. W. Oliver (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 102, pp. 33–37, pls. 3*).—This bulletin describes a method of propagating forage plants by means of cuttings, which was worked out chiefly in connection with *Medicago sativa* and *Trifolium pratense*. *Melilotus officinalis*, *M. alba*, and *Trifolium repens* have been also successfully propagated in this manner.

The method as here described applies specifically to alfalfa, and slight modifications may be necessary to apply it to other species. It is stated that at least 95 per cent of alfalfa cuttings became well-rooted in pots. Where it was necessary to transfer the plants to cold frames in midwinter the loss was as high as 10 per cent, owing to the sudden change of temperature. "No losses resulted on one occasion in the transfer of 1,800 plants to the permanent nursery rows 5 miles distant. The tops were cut back to 6 inches in height before being removed from the pots in the cold frames."

The application of the method to practical plant-breeding problems is discussed, and a list of self-sterile and self-fertile leguminous plants is given in this connection.

Some important grasses and forage plants for the gulf coast region, S. M. TRACY (*U. S. Dept. Agr., Farmers' Bul. 300, pp. 15, figs. 5*).—Brief discussions on the value and requirements of Mexican clover (*Richardsonia scabra*), beggarweed (*Desmodium tortuosum*), velvet beans (*Mucuna utilis*), guinea grass (*Panicum maximum*), and Para grass (*P. molle*) are presented.

Notes on agave and furcræa in India, J. R. DRUMMOND and D. PRAIN (*Dir. Land Rec. and Agr. Bengal, Bul. 8, 1905, pp. 195*).—Descriptions are given of the genus Furcræa and of the section euagave of the genus Agave, together with those of species naturalized in India or cultivated for their fiber. A key to the species of euagave is given, and the more important publications bearing on the subject, in addition to those mentioned in the text, are listed. The book also contains a glossary of local and commercial terms referring to the Agaveæ and certain other fiber plants, or to their products.

Alfalfa culture in Grand Isle County, L. R. JONES and H. A. EDSON (*Vermont Sta. Rpt. 1906, pp. 269-278*).—This article is a general discussion of alfalfa growing in Grand Isle County, with a tabulated summary of some of the results secured. The average total yield per acre ranged from 2½ to 6 tons. The methods of culture indorsed include thorough preparation of the soil, early seeding with grain, preferably oats, the use of 20 lbs. of seed per acre, a light annual top-dressing with commercial fertilizer, and the use of land free from weeds, especially quack grass and dodder.

On proper soil the crop had fair success and all the growers interested pronounced it profitable, particularly on certain kinds of soil. Gravelly or slaty clay loams with good natural underdrainage and gently sloping to provide surface drainage gave the best results.

The valuation of brewing barley in its relation to agriculture and brewery use and with special reference to nitrogen content, R. WAHL (*Amer. Brewers' Rev., 21 (1907), No. 6, pp. 274-278*).—This paper was presented at the International Agricultural Congress, Vienna, 1907. The author discusses European standards as not applicable to American barley, the relative high albumen content of the most valued American barleys, the barleys produced in various sections of our country, and the albumen content of barley and the enzymatic energy of malts.

A consideration of these different points leads the author to propose a system of valuation for the barleys produced in this country. He claims that they should be divided into 3 classes with reference to brewing quality, variety, and zone of culture. In the first and highest class he would place the 6-rowed barleys with an albumen content of from 10.5 to 14 per cent, medium size and weight of berry, and medium thickness of husks, and derived from the Manshury barley introduced into Wisconsin and grown principally in Iowa, Michigan, South Dakota, Wisconsin, partly in New York, Ohio, and Colorado, and also in Quebec and Ontario in Canada. In the second class he would include 6-rowed barleys relatively low in albumen content, with a percentage below 10.5, the grains being of large size and weight, the husks thick, derived from Bay brewing barley, said to be indigenous to California, and from Utah White Club, and grown principally in California, Oregon, Washington, Idaho, Utah, Colorado, and North Dakota. The third class would contain 2-rowed barleys with an albumen content below 11.5 per cent, the berry of large size and weight, thin husks, derived from Chevalier, Hanna, or other European types, and grown principally in Montana, Idaho, Colorado, and California.

The statement is made that only 6-rowed barleys of the Manshury related varieties can be considered as first class for the preparation of chill-proof beers, especially pasteurized bottle beers, and that the extract yield from fine grist under laboratory conditions from malts made from such barleys often reaches 72 to 75 per cent of the dry matter.

Owing to the great differences in American barleys the author believes that of the different factors in the valuation of European barleys only the following are adaptable to the American crop: Siftings on shaking screens of a certain size mesh, albumen content, and thickness or quantity of husk.

The influence of distance between plants on the quantity and quality of fodder beets, G. FRÖLICH (*Illus. Landw. Ztg., 27 (1907), No. 30, pp. 273, 274*).—Experiments were conducted in which fodder beets were grown at different distances. The yields secured, together with the composition of the product, were determined. The variety grown in these tests was the Friedrichswerth fodder beet, and the results were most satisfactory from rows 14 in. apart, with the plants 9 in. apart in the row.

The relation of leaf production to yield of sugar was studied, and it was found that a leaf production of 100 gm., in the case of the Friedrichswerth beet, at harvest time corresponds to a sugar production of 44 gm.

Corn-breeding work at the experiment stations, J. I. SCHULTE (*U. S. Dept. Agr. Yearbook 1906, pp. 279-294*).—A summary of the more important corn-breeding work carried on by the experiment stations in this country.

Cotton production, 1906 (*Bur. of the Census [U. S.] Bul. 76, pp. 68, maps 12*).—This bulletin is a report on the production of cotton in 1906, with comparative statistics from 1902 to 1905, and data regarding cotton growing in foreign countries. Including linters and counting round as half bales, the crop of 1906 amounted to 13,305,265 bales, as compared with 10,725,602 for 1905 and 13,697,310 for 1904.

In 1906 the Sea Island crop consisted of 57,550 bales, being the smallest produced since 1892 when 45,418 bales were secured. The cultivation of Sea Island cotton in this country, according to ginners' returns, is confined at present to selected portions of 14 counties in Florida, 24 in Georgia, and 4 in South Carolina.

The statistics presented in tabular form include data with reference to production by States and counties, the number of ginneries operated in 1906, and the production, consumption, exports and imports of the United States from 1790 to 1906, and the quantity and value of exports of cotton seed and its products from 1870 to 1906, inclusive. It is shown that about one-fourth of our production of cotton-seed oil is exported, mainly to the Netherlands, France, Germany, and Austria, and that nearly one-third of the cake and meal annually manufactured in this country is exported, principally to Denmark and Germany.

The history of the cowpea and its introduction into America, W. F. WIGHT (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 102, pp. 43-59, pls. 3*).—This bulletin is a brief history of the introduction of the cowpea (*Vigna unguiculata*) into America, presented with the purpose to establish as nearly as possible the time of its introduction and to ascertain the region to which it is native. No evidence was found that *V. unguiculata* was one of the native beans of America, but it appears to have been first introduced into Jamaica at some time between 1672 and 1687 and to have reached the southern United States later than this but before 1737. Its use apparently extended gradually northward until it reached the Potomac about 1790 or 1795.

With reference to the 2 species *V. unguiculata* and *V. catjang*, the author states that "it may be concluded from the facts so far known regarding these species that both *V. unguiculata* and *V. catjang* originally came from a region including and extending from India to Persia and the southern part of the Trans-Caspian district, and that the Persians called one or both of them by the name 'lubia' and applied that name to *V. unguiculata* in northwest India after their conquest of that region. The cultivation of *V. unguiculata* extended to China at a very early date, but the distribution of at least one of the species with the name 'lubia' had extended from the region of its origin at the beginning of the Christian era to Arabia and Asia Minor and had reached some of the Mediterranean countries of Europe at about the same time, but did not become known in central Europe until the middle of the sixteenth century."

The panicle as a factor in breeding oats and in the identification of varieties, C. Fruwirth (*Fühling's Landw. Ztg., 56 (1907), No. 9, pp. 289–301*).—This article describes the various forms of oat panicles and discusses the different characters peculiar to each as observed by the author and other investigators.

The author found from studying individual panicles that the upper spikelets produced more grains than the lower ones, and that the number of abortive spikelets and blossoms is greatest in the lower portion of the panicle and decreases as the spikelets are located nearer the top.

The author also observed variations in the hairiness at the base of the kernels. In some varieties the hairs were long and numerous, in others long but few, in some short, varying from numerous to few, and in others short and very few.

The proportion by weight of the hulls was studied and it was found that a comparison can be made only when one form of kernels is considered. It is pointed out, for instance, that if the proportion of hulls is to be taken as a factor in plant selection for breeding purposes, the grains should all be taken from corresponding portions of the panicles.

It was further observed that in addition to the spreading panicle and side-oats forms, a form may appear in which all the spikelets extend in the same direction, but which is, nevertheless, readily distinguishable from the true side-oats form. The absolute weight of the hull, as well as of the naked kernels, was found to increase from the lower to the upper part of the panicle. The double grains showed the highest percentage of hull, being followed in the order mentioned by outer kernels, single grains, and those produced toward the interior portion of the head.

It is advised that in breeding pure botanical forms the character of the spreading panicle and the hairiness of the outer kernels be considered. In the determination of the average weight of the grains or the hulls of a selected plant it is thought best to use only the outer kernels taken from the same relative position in the panicle. For crossing purposes it is advised to select the outer blossoms of spikelets in the upper whorls, as these are most likely to produce grains.

Pisum maritimum, G. Becker (*Fuhling's Landw. Ztg., 56 (1907), No. 9, pp. 325–328*).—A description of this plant is given, and the results of a few pot culture tests are reported. These experiments were conducted with the view of determining the value of this plant for cultural purposes. One of the plants attained a height of 80 cm. The root nodules located on the fine branch roots are egg shaped. The plants were not free from insect attacks.

Culture tests under humid conditions of the violet variety of Solanum commersoni and Giant Blue and Richter Imperator potatoes, P. Vincey (*Jour. Soc. Nat. Hort. France, 4. ser., 8 (1907), Feb., pp. 92–97*).—The author concludes from the results secured that the violet strain of *Solanum commersoni* is particularly valuable for sewage farms on very permeable soils, which are alternately wet and dry, according to the sewage received, but which contain quantities of plant food far beyond the necessities of the plant. For general agricultural purposes this variety is valuable on account of its resistance to mildew and its yield in starch. It is believed that this violet variety of *S. commersoni* is not identical with the Giant Blue potato, as is supposed by certain investigators.

Methods of reducing the cost of producing beet sugar, C. O. TOWNSEND (*U. S. Dept. Agr. Yearbook 1906, pp. 265–278, pls. 2, fig. 1*).—In the discussion of the subject the author suggests the following as means by which the cost of beet-sugar production may be reduced: Increasing the tonnage without increasing cost of production, improving the quality of the beets without additional expense, improving the beet in size and quality or both at additional expense, but in such ratio that the gain is greater than the outlay, providing a sufficient quantity of suitable labor at the proper time so that the beets may be kept growing without interruption, modifying the beet seed so as to render thinning unnecessary, modifying the beet so that siloing for the factory will not be required, devising machinery that will do away with hand labor, improving farming methods and operations to reduce labor requirements, and improving wagon roads and railroad facilities.

New tobacco varieties, A. D. SHAMEL (*U. S. Dept. Agr. Yearbook 1906, pp. 387–404, pls. 4, figs. 4*).—This article describes 4 varieties of cigar-wrapper tobacco produced by the author in the tobacco breeding experiments of this Department, and discusses the necessity of breeding experiments, methods of breeding, testing new varieties, and the preservation of type.

The 4 varieties described are Uncle Sam Sumatra, Hazlewood Cuban, Brewer Hybrid, and Cooley Hybrid tobacco. Uncle Sam Sumatra is a selection from a crop grown under cloth shade by M. L. Floyd in Connecticut in 1903, and Hazlewood Cuban from a crop grown under cloth shade from imported Cuban seed in the Connecticut Valley the same year. Of the type of Uncle Sam Sumatra only 28 plants were found in a field of about 40 acres containing about 50,000 plants. Pure seed of 27 of these plants was planted in 1904 and the progeny of every parent plant as grown in the test rows came uniformly true to type. Tests of the progeny of individual plants were continued in 1904 and 1905, and "the results of these and other tests have proved beyond a doubt the value of this variety for growing commercially, together with the fact that the seed comes true to type year after year when saved under bag." The plants reach an average height of about 8 ft. at the time of maturity and bear an average of about 26 leaves before topping. The cured leaves average about 16 in. in width by 20 in. in length, and are especially adapted for economical cigar-wrapper cutting. The veins are small and fine and regularly arranged, and the burn is excellent.

In 1903, 5 distinct general types of tobacco were found in the crops grown from Cuban seed and 340 plants of these types were kept for seed production, this seed being saved under bag. One of these types, No. 13, was especially desirable from a practical standpoint, and 32 typical plants were found after a careful examination of about 48 acres grown under shade. The seed of these plants, free from cross-fertilization, was saved and tested the following year. The transmitting power of the parent plants of the type was very marked, and the results of these and later tests were so satisfactory that limited quantities of seed of the type were distributed under the varietal name of Hazlewood Cuban for use in 1906. The plants of this variety under shade reach a height of about 7½ ft. at the time of maturity. The leaves have a partially erect habit of growth, the seed production is comparatively small, and the time of maturity very early. The average number of leaves per plant is about 21 after topping, and the yield may reach, under favorable conditions, 1,400 lbs. of cured tobacco to the acre. The percentage of the best grades of tobacco in the crops grown has been high. The leaves are about 18 in. long and 15 in. wide and of a round shape, adapted to economical cigar-wrapper cutting. The grain in the leaves is evenly distributed from the tip to the base; the veins are small and fine; the burn excellent, leaving a white to gray colored ash, and the tobacco has sufficient body and stretch so that when wrapped on cigars it stands handling without injury.

The Brewer Hybrid and Cooley Hybrid tobacco have been previously described (E. S. R., 18, p. 35).

The effect of climatic conditions on the composition of durum wheat, J. A. LeClerc (*U. S. Dept. Agr. Yearbook 1906, pp. 199–212, pls. 2*).—The value of durum wheat as a source of human food is discussed and the factors which influence the quality of the grain are noted. Cooperative work on this subject has been in progress for 2 years, and the comparison in this article is limited to Kubanka, a Russian or northern wheat, and Pelissier and Marouani, Mediterranean wheats from Algeria, these being the varieties grown in many different localities during this time.

The analytical results of wheat grown in arid and humid regions in 1903 show a difference of 0.57 per cent of nitrogen in favor of wheat grown in the drier localities. The percentage of ash and of phosphoric acid was influenced but little, while the weight per thousand grains was generally considerably higher in wheat from the humid and irrigated regions. It was further observed that the arid and semiarid regions produced the largest percentage of flinty grains.

In 1904 Kubanka wheat was grown in 7 localities with 15 in. or less of rain fall, and in 6 localities with more than 15 in. of rainfall or having irrigation. The grain from the drier regions contained 0.47 per cent more nitrogen than the grain produced under the more humid conditions. In other work done in 14 different localities in the Western States wheat from 7 of the places where irrigation was practiced contained on an average 12.1 per cent of protein and wheat from the remaining 7 places without irrigation contained 15.4 per cent.

A comparison of irrigated and nonirrigated durum wheats grown in Mexico showed that the irrigated wheat contained 11.1 per cent of protein and 20 per cent of flinty grains, and the nonirrigated wheat 17.7 per cent of protein and 100 per cent of flinty grains. The seed from which this wheat was grown had a protein content of 12.3 per cent, 100 per cent of flinty grains, and a weight of 38.8 gm. per thousand grains. The weight per thousand grains of the irrigated and nonirrigated samples was 29.4 and 29.2 gm., respectively.

A number of samples of Kubanka wheat were grown in Idaho and Colorado under dry-land farming and under irrigation. The dry-land samples contained on an average 2.75 per cent of nitrogen, 2.12 per cent of ash, and 1.07 per cent of phosphoric acid. The weight per thousand grains was 30.3 gm., the weight per bushel 60.9 lbs., and the percentage of flinty grains 98. The samples produced under irrigation showed an average content of 2.02 per cent of nitrogen, 2.11 per cent of ash, and 1.03 per cent of phosphoric acid, together with a weight per thousand grains of 36.6 gm., a weight per bushel of 62.7 lbs., and 55 per cent of flinty grains.

The effect of long and short periods of growth on nitrogen content and weight was also studied. The growing period of the samples under observation varied from 71 days in Oklahoma to 254 days in Washington, where the sample was grown as a winter variety. The difference in the average results between the short and long growing periods was 0.35 per cent of nitrogen, or 2.1 per cent of protein, the larger percentage of nitrogen being, as a rule, associated with the shorter growing period. It is pointed out that at North Enid, Okla., with 71 days as the growing period and 64° as the average temperature of that period, 4,544 heat units were necessary to mature the crop, while at Idalia, Colo., 157 days, with an average temperature of 58°, or 9,106 units, were required.

In studying the effect of the time and manner of harvesting, it was observed that when only the heads are harvested early the grain is small and shriveled and when harvested late the grain is plump. It was found that the percentage of nitrogen and protein was practically the same in every sample whether harvested early or late, heads separate or the whole plant, and whether the samples were protected or exposed. In the weight per thousand grains the samples harvested late weighed from 7 to 10 gm. more than those harvested early. It was also shown that the weight per thousand grains where the heads only were harvested early was 26.3 gm. and where the whole plant was harvested at the same time 28.9 gm.

Several hundred analyses made by the Bureau of Chemistry of American spring and winter wheat grown in different States show an average protein content of 12.2 per cent, as compared with 14.7 per cent for over 100 samples of durum wheat analyzed by the author.

HORTICULTURE.

Tests of the vitality of vegetable seeds, E. H. Jenkins (*Connecticut State Sta. Rpt. 1906, pt. 6, pp. 395–397*).—During the seasons of 1905 and 1906, 713 samples of field and garden seeds were tested relative to their sprouting capacity, the work being done by V. L. Churchill. A brief tabulated summary is given of the results of these tests

Data are given with regard to the average sprouting capacity of Connecticut-grown onion seed tested in 1880 and each year from 1894 to 1906, inclusive. The average sprouting capacity for 13 consecutive years was 77.7 per cent. A comparative test was made of the sprouting capacity of the following varieties: Yellow, Red, and White Globe, White Portugal, and Wethersfield Red. Red Globe gave the highest results with a sprouting capacity of 80.2 per cent, the average for the 5 varieties being about 76 per cent.

Since 1896 the station has made a test of 1,084 samples of onion seed. In the tabulated results the vitality of Connecticut-grown seed is compared with California-grown seed, the seed tested including seed of different ages from that stated to be less than one year to that stated to be between 3 and 4 years old. The California seed gave the best results except with the seed between 3 and 4 years old. Onion seed 1 year old is usually found to have a much lower sprouting capacity than new seed, although seed from a good crop 1 year old sometimes germinates quite as well as new seed from an inferior crop.

A table is also given showing the average, maximum, and minimum vitality found in tests of Connecticut-grown sweet corn less than 1 year old during the years 1904, 1905, and 1906.

The use of anesthetics in the forcing of plants, W. Stuart (*Vermont Sta. Rpt. 1906, pp. 279–293, figs. 2*).—General consideration is given to the importance of anesthetics in the forcing of plants and the results secured by European investigators along this line. The use of anesthetics at the present time is said to be confined almost wholly to flowering shrubs, such as lilacs, viburnums, deutzias, spireas, azaleas, etc. During the season of 1903–4 the author commenced some experiments to determine the value of ether in the forcing of rhubarb, the results of which have been previously noted (E. S. R., 17, p. 249). Further experiments were conducted with a view to determining whether etherized plants might not be forced without the intervention of frost. The results are here given of the work conducted during the season of 1905–6.

The experimental plants were dug early in October, stored in well-protected frames, and treated at different intervals as follows: October 30 to November 1, November 4–6, December 4–6, January 4–6, January 20–22, and February 13–15. In the first 2 trials 8 clumps were selected and divided into 2 equal lots, one of which was etherized, but with no effect. In the remaining trials the same number of clumps was used, these being divided into 4 equal lots, two of which were frozen and one lot each of the frozen and unfrozen clumps etherized. The data obtained from these trials are tabulated and show in all cases a larger total yield from the etherized plants. As in the preceding trials in 1903–4, there was a decided increase in weight of stalks pulled the first 2 pickings. In regard to the effect of freezing it is concluded that freezing rhubarb clumps, at least early in the season, is a necessary process. Etherization does not seem to perform the same function as freezing. Where the temperature is sufficiently low to prevent active growth, however, actual freezing for late forcing may not be necessary.

The writer has also investigated the action of ether on asparagus, potato tubers, apples, and palm seeds, but thus far no definite results have been secured.

An extensive bibliography is given of the literature on the use of anesthetics for forcing purposes.

Promising new fruits, W. A TAYLOR (*U. S. Dept. Agr. Yearbook 1906, pp. 355–370, pls. 8*).—Historical notes are given with descriptions and colored illustrations of several promising fruits and nuts, including the Magnate, Oliver, and Rabun apples, the Early Wheeler peach, the Banner grape, the Josephine persimmon, the Chappelow avocado, and the Alley, Teche, Curtis, Georgia, and Delmas pecans.

An orchard study of the Bitter Root Valley, R. W. FISHER (*Montana Sta. Bul. 66, pp. 67–96, pl. 1, figs. 18*).—An orchard survey was made in order to determine the most successful varieties and methods of orchard management in the Bitter Root Valley. This bulletin contains data with regard to the apple industry in Montana, with special reference to the Bitter Root Valley, the varieties grown, yields, and methods of cultivation, together with suggestions in regard to grafting, pruning, fertilizing, irrigating, harvesting, and marketing. For the benefit of the apple growers of this region, who have recently organized, the text is given of the rules adopted and used by the Hood River apple growers' union of Oregon.

A table is given showing the yields from 1903 to 1906, inclusive, produced from the 3,090 acres of apple trees now in bearing. In 1905 this production amounted to 116,763 boxes, valued at $81,734. Although the 4-year average value per acre was only $20.56, figures are given to show that orchards properly cared for are producing profitable crops. The average yield per acre of all orchards under clean cultivation on elevated land was 121 boxes per year and on bottom land 123 boxes per year. The orchards on elevated land grown in sod produced a yearly average of 54 boxes per acre, and on bottom land 101 boxes per acre, from which there appears a difference in favor of clean cultivation on elevated land of 67 boxes per acre and on bottom land of 22 boxes per acre. Throughout the valley the orchards given clean cultivation, with an occasional cover crop plowed under, are producing the largest crops, although some of the bottom lands produce profitable crops when grown in sod when attention is given to irrigation, pruning, and protection from injury by mice.

Cover crops of clover should not be left more than two seasons, and the best results are obtained when they are plowed under in the spring of the year after they are planted. Where the cover crop is left longer than this the foliage appears to be much lighter in color and the wood growth much less than with trees on land which is plowed every year.

Preliminary notes on the seedling apples of Maine, W. M. MUNSON (*Maine Sta. Bul. 143, pp. 115–139, figs. 14*).—This bulletin contains a history and description of the more important seedling apples originating in Maine. The list of apples herein given is based upon varieties listed and described at different times by Downing, Thomas, Cole, and others, and mentioned in the reports of the Maine Pomological Society. Of such varieties as are now wholly or partly extinct the descriptions are omitted. Illustrations are given of several of the more important varieties.

The winterkilling of peach buds as influenced by previous treatment, W. H. CHANDLER (*Missouri Sta. Bul. 74, pp. 47, figs. 14*).—In this bulletin the effects of severe pruning, thinning, and cultivation in the peach orchard on the hardiness of the fruit buds are discussed, and the results are given of observations made on the hardiness of different varieties.

Observations made in the station orchard during the season of 1903–4 suggest that it is possible to head the fruit trees back so severely as to produce less hardy buds on the following summer's wood. In cases where the heading back is sufficiently moderate to permit the forming of fruit buds near the base of the whips of new wood their chances of living through the winter do not appear to be lessened by the pruning. Buds on vigorous new wood finish their resting period later and are not so readily started into growth by warm periods in the winter to be killed by subsequent cold weather.

In the station orchard the trees having the smallest percentage of buds killed were those trained to a spreading open head and forced by pruning and cultivation to make a vigorous growth. The fruit on trees with spreading heads did not rot so badly as that on trees with dense heads. The fruit on trees making a fairly vigorous growth was larger than that on trees making a smaller growth, except with early varieties, with which a tree making a rather small wood growth is said to bear better fruit. Thinning the fruit enabled the tree to set more hardy fruit buds for the next crop. In those cases in the station orchard where only one side of a tree was thinned, from 5 to 40 per cent more of the fruit buds were killed by a temperature of 6° F. below zero on the side not thinned than on the side thinned.

The fruit buds of such varieties as the Elberta, Crawford, Golden Gate, and Oldmixon are said to kill badly in Missouri, since they finish their resting period early and are easily pushed into slight growth on warm days. Varieties of Chinese Cling and green-twigged types, excepting the Elberta, which are generally late in finishing their resting period, are said to be better adapted for the Missouri climate.

Although no data have been gathered relative to the effect of cultivation on the hardiness of fruit buds, information was received from one fruit grower in Missouri that in the spring of 1906 more buds were found to have come through the winter on a portion of his orchard which had received good cultivation. It is believed that the enhanced growth by cultivation aids in retarding the resting period.

Experiment station work with peaches, C. B. SMITH (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1906, pp. 399–434, figs. 6*).—This is a summary of the important results secured from investigations and experimental work with peaches at the various experiment stations in the United States. The important phases considered include a classification into races and types, tree growth, flower buds, hardiness, physiological characteristics, blooming habits, self-fertility, methods of winter protection, causes and treatment of winter injury, propagation, stocks, location and soil, treatment of trees at transplanting, cultivation, irrigation, fertilizing and cover crops, thinning, pruning, harvesting, shipping, and cold storage. Data are also given in regard to the composition of peaches, canning, and profits, together with an extensive bibliography.

New citrus and pineapple productions of the Department of Agriculture, H. J. WEBBER (*U. S. Dept. Agr. Yearbook 1906, pp. 329–346, pls. 8, fig. 1*).—Descriptions and illustrations are given of 3 new citranges, the Colman, Savage, and Rustic, a new loose-skinned orange, the Thornton, and 7 new pineapples originated under the direction of the author, and named as follows: Deliciosa, Dade, Coquina, Jupiter, Orlando, Jensen, and Biscayne.

The citranges are sister fruits of the Willits and Morton. The Colman is the only citrange thus far secured which has inherited in any marked degree the fuzzy character of the Trifoliate orange. It is practically seedless and very juicy. The Savage appears to be the most fruitful of all the citranges aside from the Rusk. While the fruit of the Rustic is not considered so good as that of the Colman and Savage it produces a bushy, low-growing tree, which it is believed will render it specially desirable for cultivation as a lawn tree or a hedge plant.

With regard to the methods of propagating the citrange varieties, the writer advises that they be budded on 2 or 3 year old seedlings of the Trifoliate orange, and again emphasizes the statement that the citranges must not be confounded with oranges, but are principally of value for culinary purposes and for making citrangeade, for which purpose they are highly recommended.

The new loose-skinned orange the Thornton, is believed to have originated as a hybrid between the pomelo and tangerine, from which cross the tangelo was also produced. As compared with the tangelo, however, the Thornton is sweet and not bitter, resembling an orange more than a pomelo, and from its general characteristics would be classed as a loose-skinned common orange, while the tangelo may be described in general as a loose-skinned pomelo.

The new pineapple hybrids, of which 6 have smooth-margined leaves, are also described in detail.

Pineapple growing in Jamaica, G. L. LUCAS (*Bul. Dept. Agr.* [*Jamaica*], *5* (*1907*), *No. 2–3, pp. 41–43*).—In this article the author states that the cause of the repeated failure of pineapple growing in Jamaica can be attributed to a persistency in ignoring the Red Spanish, generally considered the one profitable and marketable pineapple, and which variety constitutes 90 per cent of all the pineapples grown in countries where the business is successful.

The olive, L. DEGRULLY (*L'Olivier. Montpellier: Coulet & Sons; Paris: Masson & Co., 1907, pp. 223, figs. 94*).—This is a treatise on olive culture. The work is introduced by a botanical study of the olive, written by C. Flahault and formerly published in the annals of the Montpellier National School of Agriculture, 1886. Part 2 is devoted to varieties of olives grown in France, Algeria, Tunis, Italy, and Spain, including the various synonyms, and descriptions of tree and fruit, with notes on the varieties described. This is followed by directions for the cultivation of olives, including soils, methods of propagation, planting, pruning, irrigation, fertilizing, and harvesting. Part 4 consists of descriptions of the various insects and fungus diseases attacking the olive, with suggestions for their control.

Olives and olive oil, A. B. BUTMAN (*Mo. Consular and Trade Rpts.* [*U. S.*], *1907, No. 320, pp. 195–198*).—This is a brief report on the cultivation of olives and their conversion into oil in Italy. It is estimated that fully 2,000,000 acres of land are devoted to olive culture, with an annual average yield of 75,000,000 gal. of oil.

The fermentation of tea, II, H. H. MANN (*Indian Tea Assoc.* [*Pamphlet*] *1, 1907, pp. 17*).—In Part I of this report, which appeared in April, 1906 (E. S. R., 18, p. 42), an account was given of the effect of changes of temperature and thickness of spreading on the leaf, and of the period of fermentation on the process of tea fermentation with relation to the influence of these factors on the pungency, color, and body of tea liquor. The present report deals with the continuation of these investigations, together with the results obtained in an attempt to determine the effect of modifications in manufacture on the flavor of tea liquor.

In the previous work it was indicated that where fermentation was conducted between 78 and 82° F. the process is complete (in the absence of microbes) in about 5½ hours from the time of commencement of brewing. Further fermentation at this temperature had no visible effect on the amount of pungency, body, or thickness of the liquor, which qualities were greatly reduced, however, when fermentation took place in the higher temperatures. In order to produce the best results, a temperature not exceeding 82 to 84° F., a saturated atmosphere, and freedom from microbes were found to be necessary.

An attempt was made to determine whether fermentation could be successfully carried on at a considerably lower temperature than the above, from which the author concludes that fermentation should not be conducted below 75° F., since the increased time necessary to obtain the best color and body of the liquor allows microbes to multiply in greater numbers, and that after about 3 hours the flavor commences to be lost. It is stated that these facts have been unconsciously recognized in the districts where temperatures are low by spreading the leaf much more thickly than is common in warmer areas, in which cases the temperature in the interior of the fermenting mass is always at least from 2 to 3° F. higher than on the outside. The heating of the fermenting house is advised when necessary to obtain a temperature within the best limits of work.

Since the quantity of essential oil in the tea leaf is too small to permit of its being weighed directly, in his present work the author estimated the quantity comparatively by determining the amount of oxygen required to oxidize it completely. This method is explained and a table is given showing the several samples of tea which were thus analyzed as to flavor. It was found that the increase in essential oil during withering amounted to about 15 per cent. As soon as rolling begins there is a very great development of the essential oil, amounting in some cases to over 25 per cent. The oil continues to increase during fermentation, but with gradually decreasing speed. Usually the development of flavor is complete at an early stage during the fermentation process.

In 2 experiments an attempt was made to exclude the action of microbes by the use of chloroform added to the fermenting leaf. There was a considerable increase of essential oil in the chloroform samples, although this treatment is said to lead to a destruction of the enzym responsible for the production of color, as well as a rapid reduction in the soluble constituents of the liquor.

The general results obtained with respect to flavor and fermentation are, in substance, as follows: The whole of the flavor is very rapidly developed after the leaf cells are broken, and does not materially increase after 3 hours of fermentation, when a decline in the flavor is apt to take place though occasionally the amount remains constant. It is believed that this decline may be due to the action of microbes in the fermenting leaf. Up to 86° F. the temperature appears to have little influence on the formation of flavor during fermentation. With regard to the length of time required for the fermentation process there appears to be a conflict, since if the maximum of flavor is to be obtained, the time must be less than 3 hours, while if the maximum thickness of liquor is to be produced, the time should be more than 4 hours. From this the author concludes that if flavor is the primary consideration, the fermentation should be as short as possible consistent with producing a fairly good liquor, whereas if the production of a very high-grade liquor is the primary object, the fermentation should be continued as long as consistent with retaining the most flavor possible (up to 4½ hours at any rate).

Experiments were conducted to determine the amount of air required by fermenting tea. From the average of 3 experiments it is calculated that 4½ lbs. cf fermenting leaf will exhaust the oxygen from 1 cu. ft. of air. In order to obtain the best results the author advises the blowing of moist air into the room in such a way as to insure the air actually in contact with the tea being continually renewed, without, on the other hand, drying the surface of the leaf.

Investigations were also made to determine the influence of firing on flavor, from the results of which it is concluded that firing above 212° F., or long-continued firing even below that temperature and even with almost dry tea, means a loss of flavor. Since slow firing also means a loss of pungency and body, the method of increasing the speed of firing without increase of temperature appears to be restricted to putting a heavier blast on the machine or by using more machines.

Trials were made with the "Paragon" machine to ascertain how the temperature conditions varied on the different trays of an automatic drier. The temperature above the top tray ranged from 99 to 140° F., whereas below the bottom tray the temperature ranged from 236 to 247° F. Only the 2 bottom trays showed a temperature approaching that of the inlet thermometer, which was from 255 to 265° F., from which it appears that this machine is not entirely satisfactory in preventing the tea from being stewed in some of the trays.

The essential points to the ideal firing process are given as follows: A rapid raising of the temperature of the fresh leaf in a current of air sufficiently strong to carry off the moist saturated air and thus prevent stewing, and a rapid firing throughout, in which the leaf itself should never be exposed to a temperature greater than 180 to 200° F., either when wet or after becoming more or less dry. In order to determine this temperature the factory should be fitted with thermometers for taking the temperature actually on the trays, since the inlet thermometer gives in many cases absolutely no idea of the temperature at which firing takes place.

Home-grown tea, G. F. Mitchell (*U. S. Dept. Agr., Farmers' Bul. 301, pp. 16, figs. 4*).—This bulletin contains popular directions for the culture and manufacture of home supplies of tea, in which consideration is given to climatic and soil requirements, planting, cultivation, pruning, and plucking, and the curing of black, sun-cured black, and green teas, together with a note on how to prepare tea for drinking. The bulletin is introduced with a brief history of tea cultivation in the United States.

According to the author the cultivation of the tea plant in home gardens is not only profitable, but at the same time the use of the much adulterated foreign article can be avoided. The crop of an average tea bush during the picking season is given as about 3 oz. of cured tea, or about 18 lbs. to 100 plants.

Notes on the height from the ground at which flower shoots form on grapevines, C. Hugues (*Rivista, 4. ser., 13, (1907), No. 10, pp. 221–226*).—This is a discussion with regard to the location of the first fruit buds on grapevines as influenced by the variety, individuality within the variety, and the effect of climatic conditions during the previous growing season.

The book of the chrysanthemum, P. S. Follwell (*New York and London: John Lane Co., 1907, pp. VII + 97, pls. 20*).—This is a popular work on chrysanthemum culture including its history and progress, together with directions for indoor and outdoor culture of chrysanthemums, both for market and exhibition purposes. Insect pests and diseases and their control as well as the hybridizing and raising of new varieties and the preparation of blooms for exhibition are also considered. In conclusion a large number of lists are given of different types of chrysanthemums recommended for general culture, for exhibition, and for decorative purposes.

This is volume 29 in the series of Handbooks of Practical Gardening, edited by H. Roberts.

Report of the horticulturist, F. A. WAUGH (*Massachusetts Sta. Rpt. 1906, pp. 208–211*).—The principal experiments under way at the station deal with problems in the propagation and pruning of fruit trees and in the systematic study of varieties of fruit. In the present report is given a summary of experiments in mushroom culture conducted in 1904 and 1905 under the direction of F. Canning, and previously noted (E. S. R., 17, p. 971).

As a general result of the experiments the author concludes that mushrooms can often be grown profitably as a catch crop in cellars or under greenhouse benches where conditions are favorable, especially as to a cheap and reliable supply of fresh horse manure. It is further concluded, however, that the stories of sudden wealth accumulated from mushroom growing are mostly fictitious.

FORESTRY.

Report of the forester, A. F. HAWES (*Connecticut State Sta. Rpt. 1906, pt. 6, pp. 369–394*).—This is a report of operations conducted in the experimental plantations, forest nursery, and State forests, of the assistance rendered to private owners of forest planting done by the Middletown Water Company, and of fires reported for 1905 by 42 wardens.

A large number of species of conifers and deciduous trees have been planted in the experimental plats, of which the pines thus far appear to be best adapted for the sandy soil on which the trees are grown. No material difference is noted between the growth of white, Scotch, and Norway pines. The first plantations of pine were made in the spring of 1902. The average height of the white pine at the end of the growing season of 1904 was 26 in., and the average annual growth for 1905 and 1906 was 11 in. At this rate of growth it is estimated that it will take a plantation of white pine 7 years to reach the average height of 6 ft. Of the deciduous trees, white and red oak, chestnut, beech, and black or yellow locust have given the best results, but with the exception of the black locust the growth has been unsatisfactory. With the latter tree, 1-year-old seedlings 2 ft. high set out in April, 1903, had grown to a height of 8 ft. in 1906, and were bearing seed. Catalpa trees have made practically no advance since they were set out in April, 1903, having been killed back every winter.

As a result of investigations the planting of 1-year-old seedlings is recommended in preference to planting acorns and chestnuts for the production of oak and chestnut trees, since the squirrels are apt to do considerable damage to the seed. Where seed is employed a bushel of nuts per acre should be used. The total cost of planting an acre, including the cost of seed, is estimated at $5.50 for chestnut and somewhat less for oak. The expense of purchasing seedlings at $4 per thousand and planting 1 acre with 1,500 trees 5 by 6 ft. apart is estimated at $8.60. When planted 5 by 5 ft. apart, 1,700 trees are required, at a total cost of about $10 per acre. These planting distances have given the most satisfactory results.

As a means of fire protection, a system of fire lines has been established. From past experience in fighting fires these lines are now made 15 ft. wide at an initial cost of about $80 a mile. The work of repair consists of cleaning out twice during the year, at an annual cost thus far of about $15 per mile, although this cost is said to be decreasing each year. For a regular tract of 100 acres it is estimated that 2 miles of fire lines should give good protection if kept in repair.

In connection with the nursery work, observations were made regarding the number of nuts per bushel from the large seeded trees and the number per ounce and pound from the lighter seeded trees. The results are tabulated.

The total stock on hand in the nursery consists of 37,700 2-year-old seedlings and 402,900 1-year-old seedlings.

Considerable advice has been rendered to private owners and systematic working plans have been made by the station when requested. A specimen plan is given here including a general description of the area under consideration, the age of the stand, an outline of planting work, the estimated cost of stock and planting, and the conclusions as to profit.

From the years 1903 to 1906 the Middletown Water Company planted 121,292 trees of various species in the reservoir tract at an expense of $1,662.50. A list is given of the parties who have been supplied by the station with forest seedlings at cost. The total number of trees planted during the year by private owners or corporations was 92,800. The primary purpose of the State forests located at Portland and Union is to disseminate practical information regarding forestry methods, such as improvement by thinning and planting operations. In cooperation with the Forest Service of this Department the station has established permanent sample plats on which the effect of thinning on growth and seedling reproduction will be studied for a series of years.

Reports from 42 fire wardens indicate that from 8,000 to 10,000 acres were burned over during the year 1905.

Progress report of forest administration in Coorg for 1905–6, C. D. McCarthy (*Rpt. Forest Admin. Coorg, 1905–6, pp. 12*).—This is a report of progress made in various forestry operations in Coorg during the fiscal year 1905–6, together with a financial statement. The important features of the report are presented in tabular form.

National forests and the lumber supply, T. H. Sherrard (*U. S. Dept. Agr. Yearbook 1906, pp. 447–452*).—The author discusses the economic phases of the forest problem, the methods of acquiring lumber under the various land laws, the purchase of national forest timber, the effect of the national forests on the price of lumber, and gives a brief account of the management of the national forests.

It is believed that the definite result of the sale of timber from the national forests will be to sustain the lumber business, to maintain a steady range of timber values and thus to lessen speculation as well as to render possible the uninterrupted development of the great industries dependent upon wood.

Census of manufactures, 1905. Lumber and timber products, J. E. Whelchel and H. Gannett (*Bureau of the Census [U. S.] Bul. 77, pp. 69, pls. 5*).—In this bulletin, which forms a part of the report of the census of manufactures for 1905, 30 tables are given containing statistics regarding the various branches of the lumber industry of the United States, including logging, sawing, and planing operations, together with imports and exports of unmanufactured lumber and finished products. Tables are also given with reference to the timber regions of the United States. The tables are discussed in detail, together with brief historical and descriptive notes regarding the lumber industry and the distribution of the more important timber species.

The statistics bear on all the important phases of the industry, including the number of establishments, quantities and value of principal products, capital invested, number of wage-earners, wages paid, and range and distribution of timber species. In a large number of instances the figures for 1905 are compared with those of the census of 1900 and other censuses. In Table 1 a com-

parative summary is given of the statistics of the lumber industry as returned at the censuses of 1850 to 1905, inclusive, with the percentages of increase for each census period. While the number of establishments engaged in the lumber industry was 18,769 for 1850 and 19,127 at the census of 1905, the capital invested in the industry during the same period increased from $41,444,364 to $517,224,128, a gain of 1,148 per cent, and the value of products multiplied almost tenfold, from $60,413,187 to $580,022,690.

Sawmill statistics (*U. S. Dept. Agr., Forest Serv. Circ. 107, pp. 2*).—This circular consists of a compilation of reports received from over 10,000 sawmills in the United States with regard to the operations of 1905. An accompanying table shows the proportions of lumber kiln-dried and surfaced, the amount of slab-wood sold, and the proportion of logs cut on lands belonging to the sawmill operators.

Altogether 1,642 mills reported the use of dry kilns. Kiln-drying appears to be more prevalent in the South and is practiced to a less extent in the Rocky Mountain and Pacific coast States. A much larger proportion of the cut is said to be surfaced at the mills than is kiln-dried. More than 3,900 mills are reported as surfacing a portion of their cut, and for the country as a whole, at least 35 per cent is surfaced before it is shipped. Some 4,000 mills reported sales of slab wood totaling 3,503,287 cords. The percentage of logs cut on lands owned by sawmill operators ranges from 97.4 in California to 34.5 in Washington.

Seasoning of telephone and telegraph poles, H. Grinnell (*U. S. Dept. Agr., Forest Serv. Circ. 103, pp. 16*).—From previous investigations with regard to the seasoning of railroad ties (E. S. R., 15, p. 46) it was determined that seasoned timber will outlast unseasoned when both are in contact with the ground, and that dry wood is more receptive of preservative fluids than green wood. In order to determine the rate of seasoning for poles, experiments were conducted by the Forest Service in conjunction with the American Telephone and Telegraph Company, in which a total of 2,200 chestnut and cedar poles were tested.

This circular contains a description of the experiments, together with the results secured. Considerable tabular data are given with regard to the rate at which seasoning progresses in telephone poles, the effect of the time of year when timber is cut on its seasoning and specific gravity, and the amount of shrinkage during air-seasoning. From the results secured winter-cut wood appears to season more regularly than that cut at other seasons, although it does not for many months at least reach as low weight as spring-cut wood seasoned equally as long. With timber of approximately the same age and growth that cut in winter will have the greatest specific gravity and that cut in autumn the least. Shrinkage of round timbers in air-seasoning is so slight as to be disregarded. When poles are carefully cut checking during air-seasoning is comparatively slight. Serious checking may result, however, if the poles are split or shaken in felling. Whereas from the standpoint of seasoning spring and winter are the best times for cutting, winter cutting appears preferable when custom, availability of labor, and susceptibility to decay are taken into consideration.

Brush and tank pole treatments, C. G. Crawford (*U. S. Dept. Agr., Forest Serv. Circ. 104, pp. 24, figs. 3*).—This circular describes the experimental treatments to determine the effect of various preservatives in delaying the decay of the seasoned poles tested in the experiments noted in the preceding circular.

In the work here described the brush and open-tank methods were used and data are being secured on the relative increase of life of treated over untreated timber, the value of different preservatives, and the effect upon the durability of poles of air-seasoning and of soaking in water with subsequent air-seasoning. Although the test must be carried over a period of several years, information is here given with regard to the capacity of the poles green, seasoned, and soaked to absorb preservatives, the degree of penetration secured with different preservatives, and the comparative cost of treatment by the brush and open-tank methods. The methods of treatment are described and results tabulated.

With regard to the absorption capacity of poles it was found that seasoned poles absorbed nearly twice as much preservative as green poles, and the water-soaking previous to treatment appeared to have no effect on the degree of absorption. With the brush treatments no essential difference has been noted in absorption or penetration due to the season of cutting, while in the tank treatments, where only one preservative was used, the spring-cut poles absorbed most, with the cut of winter, summer, and autumn following in the order given. In the brush method the average cost per pole was about 40 cts., or 29 cts. in the case of creosote, of which 7 cts. represents the cost of oil. By the open-tank process, in which creosote was the only preservative used, the average cost per pole was 67 cts., of which 22 cts. represents the cost of oil.

In an appendix a list is given of the preservatives used, which are all more or less modified distillates of coal tar or pine tar. Plans showing the relative position of the treated, seasoned, and green poles in the two experimental telephone lines are also presented.

Varieties of chestnuts, A. BAGLIONI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 4 (1907), No. 1, pp. 39–65, figs. 8*).—This is a review of the literature on the edible varieties of chestnuts, including descriptions and range of distribution, together with a list of varieties recommended for planting in Italy. Several of the more important varieties are illustrated.

White oak in the southern Appalachians, W. B. GREELEY and W. W. ASHE (*U. S. Dept. Agr., Forest Serv. Circ. 105, pp. 27*).—In this circular considerable data are given with regard to the importance, distribution, and present stand of white oak, as well as a description of the wood and its uses, the silvical characteristics and requirements of the trees, and suggestions for the management of white-oak forests.

Of the total annual cut of hardwoods in the southern Appalachain regions, excluding Kentucky, white oak forms 49 per cent. The present stand in this region is estimated at 13,102,365 M ft. B. M. Tables are given showing the relation between the diameter breast high and the diameter of different stump heights, the height and diameter of virgin white oak at different ages, and the volume in board feet of white oak in the southern Appalachian region for diameters between 14 and 40 in. arranged in height classes.

Forest planting leaflet (White oak) (*U. S. Dept. Agr., Forest Serv. Circ. 106, pp. 4*).—This circular treats of the white oak (*Quercus alba*) with reference to its form and size, range, habits and growth, economic uses, methods of propagation, planting, cultivation and care.

The Duke's osier-bed by the river Thames between Kew and Richmond, B. V. RAMAIENGAR (*Quart. Jour. Forestry, 1 (1907), No. 2, pp. 152–156*).—The author gives an account of a 6½-acre osier-bed on the estate of the Duke of Northumberland, including a description of the growing stock and notes on the method of working, utilization of produce, expenditures of various kinds, and yield. A table is given showing the income and expenditure for the year 1905, the net revenue being £15 7s. 6d. (about $77) per acre.

Evergreens for South Dakota, N. E. HANSEN (*South Dakota Sta. Bul. 102, pp. 154–217, figs. 26*):—This bulletin is based on the experiments with evergreens conducted at the station for the past 19 years, together with the experience of planters in other parts of the State. It contains popular suggestions for the propagating, transplanting, cultivation, pruning, and management of evergreens, together with notes on winterkilling, snow-traps, and wind-breaks, and on the evergreens in the Black Hills.

Descriptions are given of the varieties of evergreens recommended for planting in South Dakota and a large number of forms are illustrated.

Quinin, camphor, and ipecac, F. J. Rosa (*Bol. Soc. Geogr. Lisboa, 25. ser., 1907, Nos. 2, pp. 89–96; 4, pp. 151–161*).—Historical notes are given with reference to the introduction and cultivation of quinin, camphor, and ipecac in the different countries of the world.

Model shade-tree work (*Woodland and Roadside, 6* (*1907*), *No. 4, pp. 40–42, dgm. 1*).—The shade trees of Newark, N. J., on all public ways and in city parks are under the care of a shade-tree commission, invested with the power to make and enforce regulations. The text is here given of the notice sent to abutting property owners, preliminary to planting operations, and sets forth the methods of the commission. A graphical diagram is also given of the uniform specifications adopted as to methods of planting.

DISEASES OF PLANTS.

Report of the botanist, G. E. Stone and N. F. Monahan (*Massachusetts Sta. Rpt. 1906, pp. 157–190, pls. 2*).—A brief outline is given of the work carried on by the station during the past year, followed by notes on a number of specific investigations.

Among these attention is called to a bacterial disease of cucumbers which has hitherto been rare on cucumbers grown under glass in Massachusetts. In the attack noted the authors believe that the conditions under which the crop was grown had considerable to do with the susceptibility to infection.

A bacterial disease of lettuce is briefly described, the object of presenting the account being to call attention to the disease, as it is reported to be causing considerable damage in numerous parts of the country. The disease results in the appearance of numerous small brownish spots on the young and tender leaves of the head. The spots are frequently quite abundant and in some cases run together, causing the destruction of a portion of the leaves.

A bacterial disease of geraniums, previously noted (E. S. R., 10, p. 648), has been observed every year since 1898. At times this disease becomes quite destructive and, from the authors' observations, is more troublesome on plants exposed to bright sunshine than upon those growing in partial shade.

Attention is called to some tobacco troubles experienced in the Connecticut Valley, particularly one which appears to be caused by improper methods of fertilization and culture. In this case the roots of the plants exhibited characteristic burning, and as there appeared to be no inclination to spread from the infected centers, the trouble is believed to be due to the injudicious use of fertilizers.

The authors state that for a number of years peach twigs showing grayish colored spots with purple margins have been received at the laboratory. An examination of these showed the presence of a species of Monilia, but it was invariably a different species from that known to occur on the fruit. Further investigations will be made to determine the effect of treatment for the San José scale on the development of this disease. In connection with this and other diseases the authors state that the use of lime-sulphur mixture for the prevention of the San José scale has proved decidedly beneficial in reducing the amount of canker, pear blight, black knot, and other diseases.

A series of potato-spraying experiments is reported in which comparisons were made between standard Bordeaux mixture, dry Bordeaux, copper phosphate, and a mixture designated as 1–2–3, which is said to contain compounds of copper, arsenic, and lime. The season was remarkably free from potato diseases and but little difference was noted in the yields of the different plats.

An account is given of the treatment of the college pond with copper sulphate at the rate of 1 part to 4,000,000 parts of water to clear it of bacteria and algal growths. The copper sulphate was applied by placing it in a coarse bag attached to a canoe, which followed concentric circles over the pond until the copper sulphate was all dissolved. Bacterial examinations were made of the water, which showed a marked falling off of the number of bacteria per cubic centimeter immediately after the treatment and a gradual increase subsequently, but the number as long as observations were made did not attain as high a count as in the original samples. Laboratory experiments with pond water were carried on with practically the same results.

A number of substances used for banding trees in connection with the gipsy and brown-tail moth investigations were tested to determine their effect on the trees. Many of these preparations, most of which are proprietary, contain petroleum in some form and were found to be more or less injurious to the trees. The objection made to the use of some of the mixtures was found to be due to the fact that they were improperly used, being applied directly to the trunk of the tree instead of upon paper bands, as recommended by the manufacturers. The authors state that of all the substances tested, Tanglefoot was the only one that did not in any way cause injury to the plant tissues when placed directly on the tree trunk. This substance has a high melting point, which is a decided advantage for the purpose.

The injurious effect of illuminating gas on trees is commented upon at some length.

A study is reported on the effect of soils of different texture on the germination and growth of seeds of various kinds. The compactness of soil as affecting germination and growth was tested by sowing seeds in boxes. In one series the boxes were filled with good loam containing 8 per cent organic matter, one box being tamped firmly and the other left very loose. In another series 2 boxes of subsoil of fine texture were employed. This soil was deficient in organic matter. Lettuce, rattlebox, and white clover seeds were sown in the different boxes. No lettuce seed germinated in the tamped loam or subsoil, while the white clover made its appearance in the tamped loam. The rattlebox seed did better than the lettuce or white clover in the soil of fine texture. All of the seeds germinated better in the loose than in the packed soils.

In another series of investigations the influence of the size of soil particles was tested by seeding with lettuce. The boxes contained sifted coal ashes, the particles of which varied from 0.0001 to 2 mm. in size. The highest percentage of germination was given by the seed sown in ashes containing particles having a size of 1 to 2 mm., while the greatest average weight of the seedlings was produced in the boxes containing ashes the particles of which had a diameter of 0.5 to 1 mm. In similar boxes filled with sand the highest percentage of germination took place in the boxes containing sand the particles of which ranged from 0.25 to 0.5 mm., while the greatest average weight of the seedlings was where the particles were from 0.5 to 1 mm. in size. Attention is called to the important difference between coal ashes and sand in respect to the absorption of moisture.

Parallel experiments were undertaken in shallow plates containing about ½ in. of coal ashes, having the same range in the size of particles as in the previous experiment, to test the effect of aeration on germination, and the results were essentially the same as in the experiment reported.

The occurrence of plant diseases in Vermont in 1906, L. R. Jones and N. J. Giddings (*Vermont Sta. Rpt. 1906, pp. 227–236, figs. 2*).—Miscellaneous notes are given on plant diseases observed during the season of 1906. Among them were a number of diseases of the potato, orchard diseases, and diseases of garden crops.

Observations on the diseases and injuries to wild and cultivated economic plants in 1904, A. A. YACHEVSKI (*Ezhegh. Svyed. Bolyez. ĭ Povrezhd. Kult. ĭ Dĭkorast. Polez. Rast.*, *2* (*1904*), *pp. 119*).—Compiled notes are given on nearly 200 species of parasitic fungi and phanerogams that were observed on cereals, forage and fodder crops, orchard and garden fruits, vegetables, forest trees, ornamentals, etc.

Can phosphates cause chlorosis? T. TAKEUCHI (*Bul. Col. Agr. Tokyo Imp. Univ.*, *7* (*1907*), *No. 3*, *pp. 425–428*).—The author investigated the effect of various phosphates when added to culture media to determine whether they could cause chlorosis of plants. He found that there was no evidence of such action.

Millet smut (Ustilago panici miliacei) and its control, I. N. TRZHEBINSKI (*Vyestnik Sakh. Promuish.*, *1906*, *No. 10*; *abs. in Zhur. Opuitn. Agron.* (*Russ. Jour. Expt. Landw.*), *8* (*1907*), *No. 1*, *pp. 100*, *101*).—The spores adhering to the seeds are successfully destroyed by soaking the latter in a solution containing 0.5 per cent of copper sulphate and 0.25 per cent of formalin.—P. FIREMAN.

The diseases of sugar beets in relation to their culture, M. HOLLRUNG (*Bl. Zuckerrübenbau*, *14* (*1907*), *No. 11*, *pp. 164–171*).—A popular discussion is given of the diseases of sugar beets, the prevalence of which depends upon conditions of cultivation. The author divides the periods of beet growth into the seedling stage, the period during which the roots are developing, and the time of making and storing reserve materials. The especial diseases accompanying each phase of growth are briefly described, and the importance of proper cultivation and fertilization during the different stages is pointed out.

The control of Texas root rot of cotton, C. L. SHEAR and G. F. MILES (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 102*, *pp. 39–42*, *fig. 1*).—A description is given of root rot of cotton due to a fungus which is referred to the genus Ozonium. In investigations carried on to control this disease, the application of fungicides and fertilizers to the soil and selection have been undertaken without any great promise of success. Based upon field and laboratory observations, the authors concluded that a lack of proper aeration of the soil is a prominent factor in favor of the development of the root fungus, and consequently a series of experiments was planned in which deep plowing in the fall, deep spring plowing, and spring subsoiling were compared.

The results obtained were so remarkable that the authors recommend as an efficient treatment deep fall plowing combined with a rotation of crops for 2 or 3 years previous to planting cotton on the land. The land should be plowed to a depth of at least 7 in., and for this purpose disk plows are recommended. In the experiments of the authors the plowing was done in December, and it is believed that still better results would have been secured had the soil been turned in November, thus giving a greater opportunity for aeration.

Potato spraying experiments, L. R. JONES and N. J. GIDDINGS (*Vermont Sta. Rpt. 1906*, *pp. 265–269*).—In continuation of the station's policy of conducting spraying experiments with potatoes for a number of years, the trials during the year covered by the report were conducted with two aims, (1) to learn the gain from the use of Bordeaux mixture and (2) the relative values of a number of commercial fungicides.

The tests of the gains from the use of Bordeaux mixture were in continuation of experiments that have been in progress for 16 years. Potatoes grown on sandy loam sprayed with Bordeaux mixture gave an increase of 28 per cent in total yield and 31 per cent in marketable crop, while potatoes grown on clay loam gained 74 per cent in total yield and 68 per cent in marketable crop.

The spray compounds used in the second portion of the experiments to compare with Bordeaux mixture were copper phosphate, dust Bordeaux, and a mixture designated as 1-2-3, which is a combined insecticide and fungicide containing arsenic in some form. The results in this series were unsatisfactory on account of the appearance of the blackleg disease, described below, and comparisons can not be sharply drawn. All of the experiments, however, showed by the appearance of the plants that the use of these compounds was favorable. None of the compounds appeared to injure the potato foliage in any way and all seemed to exert some tonic effect upon the plant aside from their fungicidal and insecticidal value.

The blackleg disease of the potato, L. R. Jones (*Vermont Sta. Rpt. 1906, pp. 257-265*).—This disease, which is said to be well known in Europe, was under the author's observation in Vermont in 1906. His attention was first drawn to it about the middle of July, when the plants were about 10 in. high. The most conspicuous symptom at this time was that the plants were below normal size, of a pale or yellowish-green color, and the leaves were more erect, giving the plant a decidedly narrowed aspect.

The author is not fully satisfied as to the cause of the trouble, and he presents various theories regarding its possible origin. Among these are the parasitism of a species of Rhizoctonia, bacterial troubles, etc. In addition the author states that an appearance almost identical with blackleg disease was produced by application of Paris green to some of the plants, the amount applied being so great as to become so lodged on the lower parts of the stems as to be plainly visible.

The leaf-blotch disease of the potato caused by Cercospora concors, L. R. Jones and C. S. Pomeroy (*Vermont Sta. Rpt. 1906, pp. 236-257, figs. 3*).—The occurrence of the leaf-blotch disease of the potato caused by *C. concors* has been previously noted (E. S. R., 18 p. 948).

This disease made its appearance on early potatoes grown in fairly rich garden soil about the time when the plants were in early blossom. A close examination of the discolored leaves showed the presence of a fungus covering the spots, the fungus being most conspicuous on the lower surface of the leaves. The spots increased somewhat rapidly, so that by the middle of July most of the lower leaves were affected. In some cases the invaded portions blackened and died, while the rest of the leaf remained a yellowish green, somewhat resembling the appearance caused by early blight.

A study of the fungus showed that it was *C. concors*, and in the authors' opinion, while not before reported as occurring in this country, it has doubtless been present for a considerable time. Its occurrence at the same time as early blight and its general resemblance to this disease have no doubt led to the confusion of the two diseases. It is believed that the distribution of this fungus will be affected by summer heat and that it will probably not be found south or west of New York.

Spraying with Bordeaux mixture is recommended as a preventive, and marked differences in varieties regarding resistance to this disease are noted. The early varieties seem to be most subject to it.

Bitter pit in apples, J. B. Farmer (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1907, No. 6, p. 250*).—In continuation of reports on the bitter pit of apples received from Cape of Good Hope (E. S. R., 18, p. 554) the author calls attention to the fact that in badly attacked varieties the disease was not confined to any special region of the apple. All attempts to establish a fungus or bacterial origin have failed, as well as cultural experiments to demonstrate the presence of a parasite. The disease seems always to develop within the flesh of the apple and to extend outward toward the skin, and in many specimens received no trace of the disease was noticed until the fruit was cut open, when the characteristic brown spots were easily identified.

In the author's opinion, the disease is due to some obscure physiological causes, and, as the cells of the affected area are always full of starch, either the pathological condition tends to affect the formation of the starch, or, more probably, the action of diastase is locally inhibited.

The leaf-spot fungus of apple and other fruit trees, J. L. SHELDON (*Torryea, 7 (1907), No. 7, pp. 142, 143*).—In a publication of the Virginia Station (E. S. R., 4. p. 354) the brown spot disease of apple was doubtfully attributed to the fungus *Phyllosticta pirina*. This same fungus has since been found to occur on the leaves of pear, quince, apple, and plum, causing a disease variously known as brown spot, leaf spot, frog eye, etc.

The author has made an examination of a considerable number of specimens of the fungus and finds that the spore characters do not agree with those originally described for the above species. From the color and other characters he believes it advisable to transfer the fungus from the genus Phyllosticta to the genus Coniothyrium, and the name *Coniothyrium pirina* is proposed.

Die back of peach trees, F. M. ROLFS (*Science, n. ser., 26 (1907), No. 655, pp. 87–89*).—The author notes the occurrence at the Missouri State Fruit Experiment Station of the die back of peach trees, due to *Valsa leucostoma*, a fungus that has been previously reported as seriously attacking cherry trees in Germany and elsewhere.

The investigations carried on at the Missouri Fruit Station indicate that the fungus is an active parasite, attacking the twigs, limbs, and trunk of peach, plum, apricot, and cherry trees. On the peach infection occurs through the buds and wounds at any time during the growing season, but its development is most noticeable during the spring months. Alternate freezing and warm periods during the winter favor the growth of the organism, and it often makes considerable advancement during the warm weather in the winter, the young shoots being frequently killed back from 2 to 15 in. Twigs killed during the winter months at first have a dark purplish color, but later the epidermis and infected areas become leathery and change to scarlet or purple, and finally to a drab color. The diseased portion of the twig soon becomes constricted, making a sharp division between the dead and living tissue, and at this point gum pockets are formed, which usually produce a copious gum flow. During the spring and summer the foliage of the infected twigs frequently wilts suddenly and takes on a blighted appearance, due to the girdling of the stems.

Infections on the older branches during the winter and early spring produce oblong wounds and the epidermis covering such wounds cracks and falls away. A callus soon forms on the edge of the injury and finally covers the exposed tissue, but does not unite. On the larger limbs and trunk, especially on the southwest side of the tree, large cankers or sun-scald wounds are formed.

On the infected areas of the limbs and trunk *Cytospora rubescens* and *Valsa leucostoma* usually develop. Inoculations made with pure cultures of *V. leucostoma* produced wounds on which *C. rubescens* invariably developed, and inoculations with pure cultures of Cytospora on peach and plum trees resulted in a constant development of that fungus.

From his experiments the author believes it safe to conclude that *C. rubescens* is the pycnidial form of *V. leucostoma*. The pustules of the two forms are constantly intermingled and resemble each other so closely that it is impossible to distinguish them without the aid of a microscope.

The Japanese plum was found to be affected in the same way as is reported for the peach.

Some observations concerning the American gooseberry mildew during the summer of 1906, G. LIND (*K. Landtbr. Akad. Handl. och Tidskr., 46 (1907), No. 1, pp. 65–73*).—A discussion of the appearance of the fungus in Sweden, the susceptibility of different varieties of gooseberries to the disease, preventive measures, etc.—F. W. WOLL.

A coffee disease in Salvador, D. J. GUZMAN (*Com. Par. Agr. [Mexico] Circ. 60, pp. 24, pls. 6*).—A description is given of a disease of coffee due to attacks of *Stilbum flavidum*, together with observations regarding the distribution of the fungus, and its effect on the crop. Spraying with Bordeaux mixture is said to hold it in check. Under the prevailing conditions the disease seems most favored during the months from March to May, particularly on those estates where the cultural conditions are favorable for the development of the fungus.

The fungus parasites of the tea plant, N. N. VON SPESCHNEW (*Die Pilzparasiten des Teestrauches. Berlin: R. Friedländer & Son, 1907, pp. 50, pls. 4*).—A report is given on the various species of parasitic fungi known to occur upon the tea plant, most of the information being drawn from the author's investigations in the Caucasus, but supplemented by data from other tea-growing countries. The fungi, of which 22 species are described, are grouped according to whether they occur on the leaves, stems, or roots. After technical descriptions of the different species and accounts of their distribution, injury caused, etc., suggestions are given for their control by spraying or by cultural methods, so far as any are known.

A serious chestnut disease, W. A. MURRILL (*Jour. N. Y. Bot. Gard., 7 (1906), Nos. 78, pp. 143–153, figs. 7; 81, pp. 203–211, figs. 6*).—Attention is called to a serious disease of a native chestnut tree, which is said to threaten the extinction of this valuable tree in and about New York City. The same disease is said to have been found in New Jersey, Maryland, and Virginia.

The number of dead and dying chestnut trees led to the suspicion that the trouble was due to a fungus, and cultures were made which readily developed on agar, bean stems, sterilized chestnut twigs, etc.

The fungus works beneath the cortex in the layers of inner bark and cambium, and its presence is first indicated by the death of the cortex and the change of its color to a pale brown, resembling that of a dead leaf. Later the fruiting pustules push through the lenticels and give the bark a rough, warty appearance. In its effect on the host, the fungus may be classed as a destructive parasite, young trees often being destroyed in 1 or 2 years, while older ones lose their branches to such an extent as to materially impair the vigor of the tree. The fungus, while being primarily injurious to the living tissues, causes greater damage by its habit of girdling the stems and twigs, thus cutting them off from further development.

At present the method by which the fungus enters the tree is a matter of conjecture, but it probably gains entrance through wounds, as the author's experiments failed to produce the disease as long as the thin brown layer of the cortex remained intact.

Experiments in which young trees were sprayed with Bordeaux mixture did not give very satisfactory results.

In the second paper, which was issued early in the fall, the author reports the rapid spread of the disease throughout the New York Botanic Gardens, so that hardly a tree has escaped infection. So far as known, the fungus does not attack any other species of tree, either in this country or in Europe. The organism has been recognized as a species of Diaporthe.

A new chestnut disease, W. R. MURRILL (*Torreya, 6 (1906), No. 9, pp. 186–189, fig. 1*).—A technical description is given of *Diaporthe parasitica* n. sp., a destructive fungus occurring on the American chestnut in New York, New Jersey, Maryland, District of Columbia, and Virginia. An account of this disease is given above.

Is it possible to combat the nematode by means of fertilizers? VIMMER (*Vyestnik Sakh. Promuish., 1906, No. 3; abs. in Zhur. Opuitn. Agron.* (**Russ.** *Jour. Expt. Landw.*), *8 (1907), No. 1, pp. 99, 100*).—The author answers this question in the affirmative, provided strong nitrogenous, phosphatic, and potash fertilizers are jointly applied.—P. FIREMAN.

A select bibliography of Italian mycology, G. B. TRAVERSO (*Flora Ital. Crypt., 1 (1905), No. 1, pp. 135*).—A list of about 1,500 titles relating to Italian mycology is given, arranged alphabetically by authors. In many instances the substance of the different articles is briefly indicated.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The game warden of to-day, R. W. WILLIAMS, Jr. (*U. S. Dept. Agr. Yearbook 1906, pp. 213–224*).— A historical statement is given of the legal status and powers of the game warden in various parts of this country, beginning with the appointment of moose wardens in Maine in 1852. At present game wardens have control of nearly all birds and animals in the different States and Territories. In some localities their work is far more effective than others on account of the friendly attitude of sportsmen and others concerned in the regulations for game protection.

The birds of North and Middle America, R. RIDGWAY (*U. S. Nat. Mus. Bul. 50, pt. 4, pp. XVII + 973, pls. 34*).—In this continuation of the author's descriptive work on the birds of North America, detailed accounts are given of the birds of the following families: Turdidæ, Zeledoniidæ, Mimidæ, Sturnidæ, Ploceidæ, Alaudidæ, Oxyruncidæ, Tyrannidæ, Pipridæ, and Cotingidæ.

The birds of the Chicago area, F. M. WOODRUFF (*Chicago Acad. Sci., Bul. Nat. Hist. Survey No. 6, pp. 221, pls. 12*).—Notes are given on the time of appearance and the frequency of occurrence of the birds observed in the northern portion of Illinois and Indiana, including a territory about 50 miles square. In addition to the notes regarding the occurrence of each species, brief mention is made of influences which are prejudicial to the multiplication of birds and on the migration and local habits of birds observed in the area under discussion.

The birds of Iowa, R. M. ANDERSON (*Proc. Davenport Acad. Sci., 11 (1907), pp. 125–417, map 1*).—An annotated list is presented of the birds observed in Iowa with mention of their feeding habits and economic importance, migration, relative abundance, breeding habits, and distribution.

Birds that eat scale insects, W. L. MCATEE (*U. S. Dept. Agr. Yearbook 1906, pp. 189–198, figs. 3*).—Lists are given of the birds known to feed upon various scale insects in this country, particularly black olive scale, oak scale, and scale insects as a group. In all, 57 species of birds are reported as feeding upon scale insects. These birds are distributed in 12 families, including woodpeckers, orioles, sparrows, warblers, wrens, nuthatches, etc. It is urged that the assistance rendered by birds in the destruction of scale insects is quite important.

Cage-bird traffic of the United States, H. OLDYS (*U. S. Dept. Agr. Yearbook 1906, pp. 165–180, pls. 2*).—According to statistics gathered by the author about 300,000 cage birds, chiefly canaries, are annually imported into the United States. An account is given of the various species of birds thus imported, their value, method of capture, shipment, care, and sale. The imported cage birds come from Europe, Asia, Africa, Australia, and elsewhere. It is suggested that the industry of raising cage birds might profitably be increased in this country.

Food habits of Kansas lizards and batrachians, F. A. HARTMAN (*Trans. Kans. Acad. Sci., 20 (1907), pt. 2, pp. 225–229*).—Observations were made on several species of lizards and batrachians observed in Kansas. In general the lizards were found to live chiefly upon grasshoppers, crickets, and beetles for the most part belonging to harmful species. The batrachia show a wider range of diet, but they feed chiefly upon insects. Lizards as a class are more active in this respect than batrachia, with the exception of the toad, which is the most beneficial of all.

Is the Gila monster a poisonous reptile? F. H. SNOW (*Trans. Kans. Acad. Sci., 20 (1907), pt. 2, pp. 218–221*).—In the author's experience no direct evidence has been obtained that the bite of the Gila monster is poisonous, but the evidence for the poisonous character of the bite as obtained by other investigators is briefly summarized.

Sex differentiation in larval insects, V. L. KELLOGG (*Biol. Bul. Mar. Biol. Lab. Woods Holl, 12 (1907), No. 6, pp. 380–384, figs. 8*).—Previous experiments by the author have shown that the sex of silkworms can not be influenced by excessive or light feeding of the larvæ during their various stages. The reason for the negative results in these experiments was found upon making a microscopic study of silkworm larvæ. The sexes are already fully differentiated at the time when the first molting appears and probably even at an earlier stage. It is considered, therefore, useless to make further attempts to influence the proportion of the sexes in silkworms by feeding.

Report of the entomologists, C. H. and H. T. FERNALD (*Massachusetts Sta. Rpt. 1906, pp. 199–205*).—Tomato plants in greenhouses may be freed of white fly by fumigation with hydrocyanic-acid gas. Considerable attention was given to the study of root maggots and remedies for scale insects. Brief notes are also given on the insect pests of the year and on cranberry insects and the oriental moth.

Three injurious insects, (*Estac. Agr. Expt. Ciudad Juárez, Chihuahua Bol. 5, pp. 23, pls. 2, figs. 3*).—Economic and biological notes are given on grasshoppers, peach aphis, and fall webworm. In combating grasshoppers the best results have been obtained from the use of a bait poisoned with Paris green. In the control of peach aphis great success has been had from the application of fertilizers and bisulphid of carbon to those plant lice which are located at the base of the trunk.

A contribution to the physiology of the museum beetle (Anthrenus museorum), A. J. EWART (*Jour. Linn. Soc. [London], Zool., 30 (1907), No. 195, pp. 1–5*).—The museum beetle is reported as causing great damage to dried plants in the national herbarium at Melbourne. The herbarium specimens have to be fumigated with carbon bisulphid at least once annually in order to prevent their destruction. An analysis of herbarium specimens showed that they contain as a rule from 9 to 11 per cent of water. The larvæ of the museum beetle appear to thrive on plants which contain less than 9 per cent of water.

An attempt was made to determine the source of the water in the body of the larvæ. A part of the water appears to be of a chemical nature, being derived from the carbohydrates in the food of the larvæ by decomposition under the action of bacteria and digestive juices. In the protection of herbarium specimens against museum beetles, it is recommended that care be exercised to exclude all materials which may absorb water.

Acariosis of oats, P. MARCHAL (*Ann. Inst. Nat. Agron., 2. ser., 6 (1907), No. 1, pp. 185–196, figs. 3*).—A description was given of the malformation caused in the head of oats by parasitism with *Tarsonemus spirifex*. This mite has caused serious injury to oats, particularly in the department of Vienne. The mite attacks chiefly oats, but is also found on barley, wheat, and other cereals. The application of an abundance of fertilizers is recommended in preventing injury from this mite.

Hylemyia coarctata, BÖRNER (*Mitt. K. Biol. Anst. Land u. Forstw., 2 (1907), No. 4, pp. 60–63, figs. 2*).—The injury caused to rye and wheat by this insect varies greatly in different years. Apparently there is no practical remedy which may be applied directly against the pest. Deep plowing of infested fields may be depended upon to bring about favorable results.

Some recent studies of the Mexican cotton boll weevil, W. D. HUNTER (*U. S. Dept. Agr. Yearbook 1906, pp. 313–324, pl. 1, fig. 1*).—According to the observations and experiments of the author and his associates it appears that the influences which assist in the control of the cotton boll weevil arranged in the order of importance are as follows: Heat and dryness during spring and summer, the ant *Solenopsis geminata* and other predaceous insects, winter cold and moisture, proliferation of the cotton bolls, parasites, cotton leaf worm, determinate growth of the cotton, and birds. The work of the ant is believed to deserve special attention. It is distributed through the cotton belt and is shown to be an important enemy of the weevil in Central America. Detailed notes are given on the percentage of weevils destroyed by this ant in cotton bolls and squares. A general description is also given of the status of the cotton boll weevil in 1906 and on practical methods for avoiding serious injury from the weevil.

The Duki fig-tree borer of Baluchistan, E. P. STEBBING ([*Indian*] *Forest Bul. 10, pp. 8, pls. 2*).—*Batocera rubus* has been reported as a fig pest since 1895. It seems not to be very widely distributed. The appearance and life history of the pest are described. It tunnels inside the stem and branches of the tree and is, therefore, difficult to combat. The only practical remedy suggested is the destruction of badly infested branches and trees.

Parasites of the grapevine, E. DURAND (*Flore et Faune des Parasites de Vigne. Montpellier: Coulet & Sons, 1907, pp. 89, figs. 55*).—Analytical tables are presented for the ready identification of the common insect pests and fungus diseases of grapes. Descriptive and economic notes are presented on these pests and recommendations are made regarding the most efficient remedies to use in combating them.

The biology and means of combating phylloxera, MORITZ (*Mitt. K. Biol. Anst. Land u. Forstw., 2 (1907), No. 4, pp. 64–66*).—The number of dead and decomposing tubercles on the roots of infested grapevines increases with the season. In combating the phylloxera the author made a comparative test of the 3 cresols and found that orthocresol was considerably more efficient than the other two.

Parasites of the olive fly, F. SILVESTRI (*Coltivatore, 53 (1907), Nos. 23, pp. 710–717; 24, pp. 742–745*).—The life history and importance of the parasites of the olive fly are discussed by the author, partly from a controversial standpoint, frequent reference being made to work along the same line by A. Berlese. It is maintained that the common parasites of the olive fly attack the living larvæ and that the ovipositor is sufficiently long to reach the larvæ in any of the olives cultivated in Italy. The parasites develop rapidly and destroy the larvæ except in cases of very slight infestation.

Insects injurious to wood in Italy, G. CECCONI (*Staz. Sper. Agr. Ital., 39 (1906), No. 10–11–12, pp. 945–990, figs. 38*).—Particular attention is given in this account to the injuries caused to trees by *Hylurgus piniperda, Hylesinus fraxini, H. vestitus, Scolytus multistriatus,* and a number of other species of bark beetles.

The large larch sawfly (*Bd. Agr. and Fisheries* [*London*], *Leaflet 186, pp. 8, figs. 8*).—An account is given of the history, appearance, habits, and injurious attacks of *Nematus erichsoni*. The larvæ of this pest may be jarred from infested trees or the trees may be sprayed with hellebore, Paris green, or lead arsenate.

Bombyx pini, G. Rörig (*Min. Bl. K. Preuss. Verwalt. Landw., Domänen u. Forsten, 3 (1907), No. 3, Anz. Beilage, pp. 57–60, figs. 4*).—A brief account is given of the life history and habits of this pest of the pine with notes on its natural enemies. In combating it the use of sticky bands about the trunks of the trees is recommended. They should be applied not later than the end of March. The operation under German conditions costs not more than $4 or $5 per hectare.

The development of the larvæ of Hypoderma bovis, H. Jost (*Ztschr. Wiss. Zool., 86 (1907), No. 4, pp. 644–715, pl. 1, figs. 3*).—The present account of the life history and developmental stages of the ox warble fly is one of the most complete and satisfactory studies of this insect which have thus far been published. The author finds that the egg of *Hypoderma bovis* does not develop on the skin of the host but begins its development in the gastric portion of the esophagus. In this position the first stages of the larva are regularly found in large numbers soon after the season when the warble flies are most numerous.

A majority of the larvæ migrate through the submucous tissue of the esophagus during the season from July to November or occasionally until February and then return to the lower end of the esophagus, from which point they bore their way through the subserous tissues of the thoracic and abdominal cavities and finally reach the spinal canal. In the greater percentage of cases the larvæ, in making this migration, follow the mediastinum, pillars of the diaphragm, renal capsule, and intermuscular connective tissue of the lumbar muscles.

In the spinal canal the larvæ live largely in the epidural tissue where they are found, as a rule, from December to March. After remaining about 3 months in this position the larvæ wander outward through the intervertebral foramina and finally reach the subcutis, where they remain from January until June.

As a rule, the life cycle of this insect requires about a year and 9 months. Some of the larvæ seem to be greatly delayed in their development and a few may fail to complete their growth. The larvæ of the first stage are supplied with rows of spines.

The rôle of the wood tick in Rocky Mountain spotted fever, and the susceptibility of local animals to this disease, H. T. Ricketts (*Jour. Amer. Med. Assoc., 49 (1907), No. 1, pp. 24–27*).—A study of the life history of the wood tick disclosed the fact that it may be found at almost any time during the winter attached to horses and cattle. The tick is almost everywhere present in the region where spotted fever occurs, and numerous experiments with guinea pigs showed conclusively that the disease may be carried by them. Gophers are readily infected with the disease, although they are not quite so susceptible as are guinea pigs. It is likely that gophers are largely responsible for the maintenance of the disease.

Ticks on fowls, A. Hempel (*Bol. Agr. [São Paulo], 7. ser., 1906, No. 10, pp. 473–475*).—The life history and habits of *Argas persicus*, *A. miniatus*, and *A. reflexus* are briefly described.

The comparative effect of certain poisons on insects, J. Barsacq (*Rev. Sci. [Paris], 5. ser., 7 (1907), No. 23, pp. 721, 722*).—A comparison was made to note the effects of barium chlorid, Paris green, and arsenate of lead upon insects in various stages of development, particularly species of Hyponomeuta. In these experiments it was found that the effect of poisons upon insects varies not only according to the amounts used but according to the structure and stage of growth of the insect. The action of poisons is greatly modified by the metamorphosis of insects and appears to be entirely suspended during the processes of molting. Immediately after molting the effect of the poison is manifested most strikingly.

The author believes that in comparing the different effects of poisons, observations should be made on the third day after the poisons are applied and that the average and maximum mortality can be determined more certainly on the seventh or eighth day. Barium chlorid is a very effective insecticide, but must be used at a strength 8 to 12 times as great as arsenicals in order to produce the desired results. It dissolves readily in water, however, and is inoffensive for man. Arsenate of lead appeared not to be as active as Paris green, but caused a rapid paralysis in the insects which ate it.

The zoological bulletin of the division of zoology, H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 5 (1907), No. 2, pp. 33–64, pls. 2*).—Brief mention is made of various practical methods for the application of sprays and of other insecticide methods. A spray calendar is also included in the bulletin.

Early spring applications of insecticides for the oyster-shell scale. The occurrence and distribution of San José scale in Vermont, W. Stuart (*Vermont Sta. Rpt. 1906, pp. 293–297, pl. 1*).—Oyster-shell scale is widely distributed in the orchards of Vermont. Infested trees were sprayed in March with lime-sulphur-salt mixture, prepared according to the formula 25:16.5:16.5:50. The mixture was boiled with steam. This insecticide gave better results than any of three proprietary remedies compared with it, but not all of the scales were killed. Spring treatment is not recommended for this insect.

San José scale has been known to be in Vermont for the past 8 years. Attention is called to the danger of infestation with this insect. Lime-sulphur wash is recommended for eradicating it.

Lime-sulphur washes for the San José scale, A. L. Quaintance (*U. S. Dept. Agr. Yearbook 1906, pp. 429–446, pls. 3, figs. 2*).—Lime-sulphur wash was first used for San José scale in California, and its use has gradually spread over the country. A historical statement is given of the early experiments with this insecticide, together with notes on the importance of the different elements in the wash, the variation in the formulas which have been proposed and the chemical changes taking place in the preparation of the wash. Recommendations are also made regarding the time of application, the necessary equipment for spraying, and the range of usefulness of the lime-sulphur preparations.

Bacteriological studies on foul brood and sour brood of bees, R. Burri (*Bakteriologische Untersuchungen über die Faulbrut und Sauerbrut der Bienen. Aarau: H. R. Sauerländer & Co., 1906, pp. IV+40, pl. 1, fig. 1*).—A series of bacteriological studies was carried out for the purpose of determining the bacterial cause of foul brood and sour brood.

It is found that in Switzerland foul brood may be caused by infection with *Bacillus alvei* and also by another bacillus which appears to be a new species and is difficult to cultivate. The two organisms may be distinguished by the fact that in dead larvæ *B. alvei* is found in the form of rods and spores and produces a strong odor, while the other bacillus causes no odor and is found only in the form of small spores. Other species of bacilli were found not to be connected with foul brood.

Larvæ affected with sour brood are characterized by an acid odor, dirty yellow color, and increased hardness of the chitin coat. In affected larvæ large numbers of bacteria resembling lactic-acid bacilli are found. Both foul brood and sour brood may occur simultaneously in the same hive, but the author believes that foul brood is usually caused by the new species of bacillus which he has discovered.

Report on a disease of bees in the Isle of Wight, A. D. Imms (*Jour. Bd. Agr. [London], 14 (1907), No. 3, pp. 129–140, figs. 3*).—The bee keepers of the

Isle of Wight have referred to a bee epidemic in that island as paralysis, although the symptoms did not agree with those of this disease. The disease in question appears to have been first noticed in 1904 and has spread rapidly since that time, causing serious losses in many parts of the island. Bees affected with the disease are unable to fly more than a few yards and soon die after attempting to crawl up grass stems or other objects.

The disease is confined almost entirely to adult bees and affects chiefly the digestive system; in fact it may be described as an excessive enlargement of the posterior parts of the intestine, particularly the colon and rectum. These parts become distended, chiefly with pollen grains. Certain bee raisers claim that they are able to prevent the occurrence of this disease by artificial feeding of swarms, but this method does not always give satisfactory results. The author recommends the destruction of diseased swarms and the thorough sterilization of the hives.

The bee epidemic in the Isle of Wight (*Brit. Bee Jour., 35 (1097), No. 1302, pp. 221-223, figs. 3.*)—The reports concerning the prevalence of a bee epidemic in the Isle of Wight have been considerably exaggerated. It is now believed that the disease is not paralysis as had been supposed, but is apparently identical with a disease known in Germany as "May" disease.

Annual report of the royal sericultural station, Padua (*Ann. R. Staz. Bacol. Padova, 34 (1907), pp. 125*).—In a preface to this report the director of the station, E. Verson, calls attention to the negligence observed among a considerable percentage of the population in carrying on sericulture in a satisfactory manner. This matter was called to the attention of government officials and a commission was appointed to investigate the status of sericulture. The commission recommended the establishment of a peripatetic chair of agriculture for the purpose of disseminating encouragement and information regarding silk raising.

The present status of sericulture in the provinces of Bari, Foggia, and Lecce is discussed by E. Quajat (pp. 29-39). The causes of flaccidity in silkworms are discussed by E. Verson (40-49). This is believed to be a distinct disease which may arise from the cooperation of a number of predisposing causes. The disease is observed much more frequently when the silkworms are neglected than on the premises of careful and progressive silk raisers. The same author made a study of the effect upon silkworms of washing the mulberry leaves in disinfectants (pp. 50-57). For this purpose fluorid of silver was used in washing the leaves as compared with dry leaves and leaves merely moistened with water. The weight of the cocoons was greatest in case of those which fed upon leaves treated with fluorid of silver, but this increase of weight was apparent rather than real, since the amount of silk seemed to be no greater. The larvæ fed upon disinfected leaves showed no diminution of mortality.

The leaves of *Morus alba* and *M. nigra* were compared as food for silkworms by E. Quajat (pp. 58-80). The quality of cocoons obtained by feeding the worms on *M. nigra* was superior, as was also the tenacity of the silk. The elasticity of the silk was the same in both cases. The same author also gives descriptive notes of 4 races of Chinese silkworms imported into Italy. E. Verson tested the value of tetrachlorid of carbon in killing the chrysalids. This chemical as compared with the ordinary method of steaming was found to have no advantage and injured the silk to some extent. Biological notes are also given on a number of races of the silkworms and on the manner of depositing the eggs. As in previous numbers of this report an elaborate bibliography relating to silkworms has been collected (pp. 107-124).

Some silkworm moth reflexes, V. L. KELLOGG (*Biol. Bul., 12 (1907), No. 3, pp. 152-154*).—The author reports a number of observations in which it appeared that in mating, the male silkworm is guided by the sense of smell. It was also found that headless female moths live as long as normal individuals and lay the usual number of eggs.

The consumption of mulberry leaves as related to the breeds of silkworms and the quality and quantity of silk, P. Bucci (*Staz. Sper. Agr. Ital., 39 (1906), No. 9, pp. 769–816*).—A large number of observations were made regarding the quality of silk as affected by methods of feeding silkworms and the detailed results are stated in tabular form.

Flaccidity of the silkworm, C. Ciarpella (*Arch. Farmacol. Sper. e Sci. Aff., 6 (1907), No. 2–3, pp. 120–126*).—The conditions under which flaccidity occurs in silkworms are briefly described by the author. It is believed that this disease is transmitted by ingesting food contaminated with the pathogenic micro-organism. This organism may be present at any time in the intestines of silkworms, but gains entrance to the tissues of the body at times when the resisting power of the worms is at low ebb.

FOODS—HUMAN NUTRITION.

Hygiene of nutrition, J. Rouget and C. H. A. Dopter (*Hygiène Alimentaire. Paris: J. B. Baillière & Sons, 1906, pp. 319*).—This handbook, which constitutes volume 4 of a series of treatises on hygiene published under the direction of P. C. H. Brouardel and E. Mosny, summarizes and discusses data on vegetables, fruits, and cereals, meat and fish, dairy products, eggs, etc., preparation of food, condiments, preserved fruits, beverages, food adulterations, overabundant and insufficient nutrition, foods as accidental carriers of bacteria and as causes of disease, and related questions.

The nutrition investigations of the Office of Experiment Stations and their results, C. F. Langworthy (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1906, pp. 359–372*).—Attention is directed to the lines of investigation which have been especially followed in carrying on the nutrition investigations of this Office, and some of the principal results obtained are pointed out.

Food value of corn and corn products, C. D. Woods (*U. S. Dept. Agr., Farmers' Bul. 298, pp. 40, figs. 2*).—The structure, composition, and milling of corn, methods of cooking, corn breakfast foods and other corn products, the digestibility of foods made from corn, green corn as a vegetable, and related questions are considered in this summary of available data on the composition, digestibility, nutritive value, and place in the diet of this important cereal. In composition corn compares favorably with other cereal foods. As regards its digestibility, experiments indicate that "the carbohydrates are almost completely utilized by the body, no matter how the grain is cooked. The method of preparation, however, apparently makes considerable difference in the digestibility of the protein. . . .

"The corn breakfast foods and other corn products have much the same digestibility as corn meal when cooked in similar ways. The variations which have been noted with the different corn breads and other corn dishes are of the same character as those observed with similar foods made from wheat flour of different sorts."

Corn, like other grains, "contains too little protein in proportion to its fat and carbohydrates to supply the body with nutritive material in the proper proportion, and it should be combined with materials rich in protein, such as lean meat, milk, cheese, dry beans, etc. When thus combined it is a healthy, nutritious, and inexpensive food and has been proved by common experience to be wholesome, palatable, and a welcome addition to the diet.

"Considering all of its uses, corn is one of the most important cereal foods from the standpoint of palatability, nutritive value, and digestibility. It may be prepared for the table in a great variety of ways, and in some form or other is deservedly used in the majority of American homes."

Nuts and their uses as food, M. E. JAFFA (*U. S. Dept. Agr. Yearbook 1906, pp. 295–312, pl. 1, fig. 1*).—The flavor, composition, and digestibility of nuts and their place in the diet are considered, the preparation and characteristics of nut butter, nut paste and preserves, nut flours, and other nut products are described, and data on the general subject of nuts and their uses as food are summarized.

In general, according to the author, "it may be said that nuts are a very concentrated food, even more so than cheese; but when rationally used they are well assimilated and may form a part of a well-balanced diet. Nuts are a very valuable source of protein and fat, these two nutrients being the characteristic constituents of the more common nuts, of which the walnut and cocoanut may be taken as types. In nuts like the chestnut, carbohydrates are a characteristic constituent. For most families it is undoubtedly wiser to use nuts as part of the regular diet than as a condiment or supplement to an otherwise hearty meal.

"Vegetarians and others who use nuts in place of meat should not depend upon them as the main food supply, but should supplement them with more bulky foods with a low content of protein and fat. As a whole, nuts may be classed among the staple foods, and not simply as food accessories. At usual prices, nuts are reasonable sources of protein and energy. . . .

"Though less subject to contamination than many other foods, nuts should be handled and stored under good conditions, and especially should be protected from dampness and insect enemies."

Infant feeding and infant mortality among the Chinese, WIENS (*Arch. Rassen u. Gesell. Biol., 4 (1907), No. 2, pp. 224–227*).—On the basis of personal observation and other available data the author discusses infant feeding in northern China.

In general, the children are breast fed for 18 months and sometimes for 3 or 4 years. Cow's milk is not used by the Chinese, and when the children are weaned they are given porridge made from wheat flour or from millet meal with millet bread and similar foods, and later eggs and a little meat, that is, they gradually become accustomed to the mixed diet used by adults. In well-to-do families a special sort of rice is used, as well as lotus roots, cakes from bean flour, various dishes made from wheat flour, and fruit. When it was necessary to wean very young children on the cereal products mentioned, fatal results were almost always noted.

A plea for the use of oatmeal in the dietary of children, C. WATSON (*Brit. Med Jour., 1907, No. 2417, pp. 985, 986, figs. 2*).—In the author's opinion, oatmeal porridge is a very satisfactory food for children from the third year onward. "Breakfast is the meal into which oatmeal should most largely enter, the best form of administration being porridge and milk, which should be followed by a glass of milk and some bread and butter." The author believes that it is better to omit meat from the meal. His high opinion of oatmeal is in part based upon the fact that in experiments with young rats the thyroid gland was much more highly developed on oatmeal than on a diet of bread and milk.

Buttermilk feeding, H. C. CARPENTER (*Jour. Amer. Med. Assoc., 48 (1907), No. 19, pp. 1576–1580, dgms. 12*).—A discussion of the uses of buttermilk in infant feeding, with reports of a number of cases. On the basis of experience, the author considers fresh buttermilk most excellent temporary food "for infants suffering from intestinal indigestion, enteritis, and marasmus." No unpleasant effects from the administration of fresh buttermilk have been noted, and infants almost invariably take it well. In the author's opinion, "whatever success has attended the use of buttermilk, is not so much due to the absence of fat as to the great ease with which the proteid of buttermilk is digested. . . . Several who were unable to digest 0.75 per cent of calcium casein digested perfectly the 2 per cent to 3 per cent of casein lactate in the buttermilk."

Milling characteristics of Australasian wheats, F. B. GUTHRIE and G. W. NORRIS (*Agr. Gaz. N. S. Wales, 18* (*1907*), *No. 4, pp. 295–307*).—Percentage of milling products, color of the flour, strength, gluten content, character of the gluten, and other data were recorded for a number of samples of wheats grown in Australia.

The author notes that a number of varieties yield flours of high strength and that they retain this characteristic under cultivation in regions where hitherto rapid deterioration of wheat in this respect has been observed.

Structure of the starch grain, H. KRAEMER (*Amer. Jour. Pharm., 79* (*1907*), *No. 217–229, pl. 1, figs. 3*).—A summary of experimental evidence and other data included in this paper led to the conclusion that "the starch grain consists of colloidal and crystalloidal substances, these being arranged for the most part in distinct and separate lamellæ, that is, at the point of origin of growth, and in the alternate lamellæ the colloidal substance preponderates, associated with the crystalloid cellulose; whereas in the other layers the crystalloidal substance, consisting for the most part of granulose, occurs in greater proportion."

The chemical composition of cooked vegetable foods, II, KATHARINE I. WILLIAMS (*Jour. Amer. Chem. Soc., 29* (*1907*), *No. 4, pp. 574–582*).—The author reports an extended study of the composition of cooked cereal foods as compared with the raw product. Earlier work has been noted (E. S. R., 15, p. 885).

The pentosan and methyl pentosan content of vegetables, J. SEBELIEN (*Chem. Ztg., 30* (*1906*), *p. 401; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 13* (*1907*), *No. 10, p. 638*).—The author distilled with hydrochloric acid a number of vegetable products, such as wood of different sorts, hay, seaweeds, barley, bran, oil cakes, carrots, and turnips, and found that the resulting furfurol contained only small amounts of methyl furfurol and that the ratio of methyl pentosan to pentosan was usually less than 1. Carrots and turnips, he states, contained respectively 2.59 and 2.93 per cent methyl pentosan on a dry-matter basis, and 8.43 and 6.67 per cent pentosan.

Dika butter, E. MILLIAU (*Agr. Prat. Pays Chauds, 7* (*1907*), *No. 48, pp. 189–199*).—Dika butter, a culinary fat prepared from the seeds of *Irvingia gabonensis*, is, the author believes, destined to become an important article of diet. It possesses a delicate flavor not unlike that of cocoa butter and resembles this and other vegetable culinary fats in chemical character, as the analytical data show. The method of manufacture is described. The cake remaining after the extraction of the fat is stated to be an important feeding stuff. When well prepared, dika butter has a decided advantage in that it does not readily spoil.

Concerning cocoa and chocolate, J. DEKKER (*Arch. Pharm., 245* (*1907*), *No. 2, pp. 153, 154*).—A polemical article.

The quantity of calcium oxalate in cinnamon and cassia bark, J. HENDRICK (*Analyst, 32* (*1907*), *p. 14; abs. in Chem. Ztg., 31* (*1907*), *No. 24, Repert. No. 21, p. 126*).—None of the cassia samples contained as much calcium oxalate as the lowest amount found in cinnamon bark. The investigation also showed that wild cinnamon could be distinguished from ordinary Ceylon cinnamon, since it contains about twice as much calcium oxalate.

The examination and valuation of raspberry juice and raspberry sirup, P. BUTTENBERG (*Arch. Pharm., 245* (*1907*), *No. 2, pp. 81–97*).—A summary of investigations on the subject with special reference to determining the purity of raspberry juice and raspberry sirup.

Marmalade making by English methods, C. RAPP (*Die Marmeladenfabrikation nach englischem Verfahren. Magdeburg and Vienna: Schallehn & Wollbrück, 1907, pp. 124, figs. 44; rev. in Österr. Chem. Ztg., 10 (1907), No. 8, p. 107*).—The author discusses materials used in marmalade making, different sorts of machinery, handling and shipping goods, and related questions.

Concerning Liebig's meat extract, II, KUTSCHER (*Zentbl. Physiol., 21 (1907), No. 2, pp. 33–35*).—Oblitin, histidin, and a new meat base for which the tentative name "vitiatin" is proposed, were identified as constituents of meat extract. Vitiatin is apparently related to guanidin, methylguanidin, dimethylguanidin, creatin, and creatinin, and the author hopes that it will prove to be the mother substance of these bodies. Earlier work has been noted (E. S. R., 17, p. 790).

Preservation of meat (*Österr. Mil. Ztschr., 2 (1906), p. 1817; abs. in Hyg. Zentbl., 2 (1907), No. 14, pp. 451, 452*).—In the system of preserving meat described, the meat is dried in a vacuum at a temperature less than 0° C. It is stated that the flesh thus dried remains porous, keeps well, and, after soaking in water, closely resembles fresh meat in appearance and flavor.

A contribution to the chemistry of the bleaching of flour, S. AVERY (*Jour. Amer. Chem. Soc., 29 (1907), No. 4, pp. 571–574*).—From experiments which were carried on at the Nebraska Experiment Station with different bleaching agents, the author concludes that "the maximum bleaching effect, without regard to the quantity of the reagent, can be obtained by the use of bromin. The other reagents follow in the order named: Chlorin, sulphur dioxid, nitrogen peroxid. A given weight of nitrogen peroxid will bleach a far greater quantity of flour than the same weight of any of the other reagents mentioned. All samples of flour bleached with nitrogen peroxid, in so far as tested, respond to the Griess test for nitrites. Samples stored in laboratories and in mills where bleachers are used, commonly respond to the same test. A sample exposed, however, for 13 months in an office not containing any electric or gas lights failed to respond to the Griess test.

"A sample of the flour under consideration was placed in a layer $\frac{1}{64}$ in. thick between plates of glass. The plates were bound together at the edges with adhesive tape. The whole was exposed to the action of sunlight by placing in direct sunlight and reflecting also the rays against the reverse side by a mirror. The sample was bleached by an exposure of 2 hours.

"Nitrogen peroxid mixed with an excess of ozone shows the same bleaching effect as when mixed with air. The bleaching is due solely to the peroxid present."

The specific yellow coloring matter of wheat occurs dissolved in the wheat oil and may be extracted with benzene or other solvents, the extracted flour, as the author points out, being almost white. It was found that exposure to direct sunlight removed the color of a benzene solution of wheat fat in 3 hours. When a sample was shaken with a very dilute solution of nitrous acid bleaching was instantaneous. With dilute bromin water the effect was less rapid. Slow bleaching was effected with a solution of sulphurous acid in large excess.

"Hydrogen peroxid solution, on shaking with the benzene solution of the oil and coloring matter, gave no bleaching effect. This was true in acid, neutral, and basic solutions.

"A solution of the colored oil in acetone was treated with a trace of water and aluminum amalgam. The color was not changed. Zinc dust and acetic acid were also without effect."

As regards the action of reagents on the oil without the solvent, it was found that it was rendered nearly colorless by cautiously applying nitrogen peroxid, chlorin, or bromin. "The first effect is to destroy the yellow color. Secondary effects, such as causing the oil to become red brown, are obtained by an excess of the reagent or by heating or by both."

In the author's opinion, the nitrous acid used in bleaching apparently forms a fairly stable compound, presumably by uniting with the mineral matter of the flour to form a salt. An excess of nitrogen peroxid discolors the gluten of the flour.

On the basis of unpublished data obtained at the Nebraska Station, tests with numerous samples of commercially bleached flour did not indicate that bleaching had any apparent effect on bread-making qualities.

In general, whatever the nature of the coloring matter in wheat flour may be, it appears, according to the investigations reported, to be indifferent to ordinary oxidation or reduction or to acids or alkalis. The minute traces of yellow coloring matter present in flour can be bleached with such minute amounts of nitrogen peroxid "that it is difficult to detect any effect on the flour other than the bleaching and the presence of traces of nitrites. The extreme sensitiveness of the coloring matter to nitrous acid suggests that the color may be dependent on the presence of an amino group."

The effects on the human system of Louisiana manufactured sirups and molasses, R. E. Blouin, P. E. Archinard, and J. A. Hall, Jr. (*Louisiana Stas. Bul. 94, pp. 46*).—In the manufacture of Louisiana cane sirups and molasses the juice is treated with lime and sulphur fumes, and a series of investigations was undertaken to study the effects of sulphites on the human system.

Twelve negroes served as subjects of the tests, which covered 5 periods of 1 week each. In the first and fifth period a normal mixed diet without the sirup was followed and in the remaining periods sirup or molasses, which contained from 161 mg. to 928 mg. of sulphur as sulphites per kilogram was added to the ration, the amount of molasses or sirup eaten per day averaging 120 to 421 gm. per man. The subjects were not aware of the nature of the experiment.

Throughout the test examinations were made of the blood of the subjects and records were kept regarding their physical condition, body weight, etc. Among the conclusions drawn were the following:

"From a practical standpoint the experiments on molasses feeding were carried on for a sufficient length of time and on a scale large enough to test the effects of these foods on the human subject in ordinary health. . . .

"As in none of our cases were the body functions interfered with, in each one the body weight increased, and as the blood steadily increased in number of red blood cells, in the percentage of hemoglobin, etc., it must be admitted that these subjects were gaining in health and neither doing nor taking anything prejudicial to their physical well-being.

"The amount of molasses consumed, although in some instances very large, does not seem to have had any deleterious effects on the functions, weight, and blood condition of the subjects, but rather to the contrary.

"We are, therefore, free to conclude that molasses feeding, even when said molasses contains as high as over 900 mg. per kilo of sulphur as sulphites, can be carried on under ordinary circumstances without prejudicial effect to health."

The molasses and sirup used were analyzed.

General results of investigations on the effects of salicylic acid and salicylates on health, H. W. Wiley (*Chem. Ztg., 31 (1907), No. 23, pp. 301, 302*).—The data summarized have been noted from another publication (E. S. R., 18, p. 462.)

Food inspection decisions (*U. S. Dept. Agr., Food Insp. Decisions 74, pp. 3; 75, pp. 2; 76, pp. 13*).—These publications include, respectively, the decisions which have been rendered under the provision of the pure food law regarding certificates for imported meats and meat-food products of cattle, sheep, swine, and goats; the labeling of mixtures of cane and maple sirups; and dyes, chemicals, and preservatives in foods.

Adulteration of food (*Rpt. Inland Rev. Canada, 1906, pt. 3, pp. 375*).—A summary of data showing the scope and extent of the year's work of the Canadian Inland Revenue Department in respect to food and food adulteration. The results have appeared in detail in Bulletins 106 to 124 of the department, which are reprinted as appendixes. These bulletins have been noted from time to time as they appeared.

Law with respect to foods in Germany, G. LEBBIN and G. BAUM (*Deutsches Nahrungsmittelrecht. Berlin: J. Guttentag, 1907, vols. 1, pp. 555; 2, pp. 224; rev. in Chem. Ztg., 31 (1907), No. 28, p. 361*).—This work is designed for the use of students, physicians, chemists, and manufacturers. The first volume is concerned with fines, duties, and other legal questions, while the second contains a summary of data on analytical methods with special reference to the needs of legal chemists.

Observations on human chyle, T. SOLLMANN (*Amer. Jour. Physiol., 17 (1907), No. 5, pp. 487–491*).—The chyle was obtained from a subject who had been wounded in the thoracic duct and operated on in such a way that the lymph flowed from the wound in a continuous stream for several days. When the subject fasted the chyle was clear; at other times it was more or less creamy in appearance and when creamy would clot or jelly on standing. Analyses of the chyle are reported as well as data upon the excretion of different drugs in chyle and related topics.

Do eggs affect the excretion of uric acid? P. FAUVEL (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 14, pp. 730–732*).—In the experiment reported 150 gm. egg per day was added to an otherwise purin-free diet, this period being preceded and followed by a similar diet without eggs. As shown by the data recorded, eggs did not increase the uric-acid output or the excretion of xanthouric bodies.

Total metabolism of iron and calcium in man, H. C. SHERMAN (*Proc. Soc. Expt. Biol. and Med., 4 (1906), No. 2, pp. 21, 22; abs. in Chem. Abs., 1 (1907), No. 5, p. 582*).—The balance of income and outgo of iron and calcium was determined in 3-day experiments with man. "On a diet with 0.0057 iron and 2.65 calcium oxid there was equilibrium with respect to iron and retention of calcium. With 0.0065 iron and 0.14 lime, or 0.0071 iron and 0.13 calcium oxid, there were losses of both iron and calcium." The results confirm the statement previously made that a deficiency of calcium in the diet may lead to a simultaneous loss of iron.

Thermodynamics of muscles, K. BÜRKER (*München. Med. Wchnschr., 54 (1907), No. 2, pp. 59–62; abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 2 (1907), No. 6, p. 222*).—The author's experimental methods permit the study of muscle activity and show that under the different external and internal influences which different seasons bring about the muscle possesses varying quantities of energy-yielding material. It also appears from his results that in the case of raising and lowering a weight isothermic energy is involved in the lowering, though in much less degree, as well as in the raising. Other questions are also considered.

Protein cleavage and labored breathing, C. VOIT (*Ztschr. Biol., 49 (1907), No. 1, pp. 1–36*).—An extended summary and discussion of the changes in nitrogen excretion observed when breathing becomes labored, based in a large measure upon the author's own investigations.

The increased nitrogen excretion which, it is pointed out, has been practically always noted in experimental studies of the question, in the author's opinion is dependent upon the muscular exertion just as it would be in other cases of muscular activity. The cleavages due to muscular work and to dyspnœa are, therefore, of the same character. Increased nitrogen excretion under certain pathological conditions and related questions are also discussed.

ANIMAL PRODUCTION.

Commercial feeding stuffs, H. J. Wheeler et al. (*Rhode Island Sta. Bul. 119, pp. 89-107*).—The 177 samples examined under the State feeding-stuff law included animal meal and bone, cotton-seed meal and feed, new and old process linseed meal, gluten feed, brewers and distillers' grains, wheat middlings, wheat bran, mixed feed, provender, hominy meal, horse feed, dairy and stock feed, poultry feed, and miscellaneous feeds.

Most of the feeds were essentially as guaranteed. Several samples of horse feed, however, were below standard. The cotton-seed meal recently examined, according to the authors, is not of as good quality as formerly.

"This is explained by some manufacturers as being due to the wet weather the previous autumn, and to consequent injury to the cotton seed. On the other hand it is alleged, by parties who ought to know, that some of the mills are introducing more ground cotton hulls than formerly. Whatever the cause, the attention of the consumers should be called to the facts."

As regards mixed feeds, cheap guaranteed material is being sold at present, it is pointed out, which contains corn cobs, rice hulls, or other material of little or no value as feed.

"On this account many of the manufacturers of the genuine article are now branding their goods as consisting of 'pure wheat bran and middlings,' or they are guaranteeing the percentages of fat and protein which the goods contain.

"When one considers that good mixed hay, even if free from clover, contains from 6 to 7 per cent of protein, that mixed hay and clover contains from 10 to 11 per cent of protein, and that pure clover hay contains from 12 to 13 per cent of protein, one is astounded that so many feeders of stock continue to purchase the commercial feeds of low grade at the prevailing prices. So long as such conditions exist, it is the consumer's own fault if he concludes that farming does not pay."

Forage plant investigations, H. G. Knight, F. E. Hepner, and A. Nelson (*Wyoming Sta. Rpt. 1906, pp. 35-37*).—Noted from another publication (E. S. R., 18, p. 229).

Summary of recent investigations of the value of cacti as stock food, D. Griffiths and R. F. Hare (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 102, pp. 7-18, pl. 1*).—Analyses are reported of a number of samples of cactus and cactus fruits, including both the whole fruit, pulp, and seed. In the case of a number of samples of cactus forage ash analyses were also made. The following table shows the average results obtained with the different sorts of cacti:

Average composition of cactus forage.

	Spines.	Water.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Prickly pears	0.44	84.26	0.78	0.34	9.04	2.41	3.06
Cane cacti	.79	78.47	1.41	.63	12.30	3.59	3.61
Miscellaneous cacti	1.08	87.88	1.05	.41	7.22	1.76	1.67

"On account of several practical considerations the prickly pears are of much more value than either of the other 2 groups. They are more numerous in the wild state, they adapt themselves to cultivation more readily, make a more rapid growth, and are more readily propagated from cuttings, all of which are of vital importance in the economic use and handling of the crop. Practically all of the Mexican prickly pears are fed to stock to a greater or less extent, especially those growing where fodder is the most scarce, but there is only one cylindrical-jointed species (*Opuntia imbricata*) which is used to any appreciable extent. The experience of the writers has shown that *Cereus giganteus* is readily eaten by cattle when chopped up, but they know of no actual feeding having been conducted with it on any commercial scale."

As regards cactus rations the authors point out that 40 lbs. of cactus with 10 lbs. of wheat bran and 12 lbs. of corn stover would furnish nutritive material in about the proper proportion for milch cows. "If a ration is desired in which the cactus is fed with dried brewers' grain and cotton-seed meal, it could be made by feeding 60 lbs. of cactus with 14 lbs. of brewers' grain and 1 lb. of cotton-seed meal." Other rations are also suggested.

In a discussion of the food value of different parts of the plant, it is pointed out that the seeds of many varieties, particularly of the genus Opuntia, are hard and woody and to a great extent at least pass through the animals unchanged. With other cacti the seeds are very different in character.

"There is no doubt that burros, which commonly feed upon the fruits of the viznaga (*Echinocactus wislizeni*), get a deal of nourishment out of the seeds, which are very oily and easily masticated."

Other questions connected with the conditions favorable to the growth of prickly pears, the nomenclature of cacti, and related questions are discussed and some data are given regarding the use of cacti in Mexico as human food.

The digestibility of cattle foods, J. B. LINDSEY, E. B. HOLLAND, and P. H. SMITH (*Massachusetts Sta. Rpt. 1906, pp. 96–156*).—The digestibility of a number of feeding stuffs was studied with sheep, the same methods being followed as in earlier work of which this is a continuation (E. S. R., 17, p. 279). The average results obtained follow:

Coefficients of digestibility of feeding stuffs in experiments with sheep.

Kind of feed.	Number of tests.	Dry matter	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
		Per cent.	*Per cent.*	*Per cent*	*Per cent*	*Per cent.*	*Per cent.*
Soy-bean fodder	3	64.82	80.26	67.50	74.61	47.55	39.29
Malt sprouts	3	81.87	75.92	86.60	85.30	99.42	19.12

Some of the conclusions which were drawn follow: "The soy-bean fodder appears to be slightly less digestible than that of other legumes, due in all probability to the tough woody stems which are characteristic of the plant. Note the low digestibility of the fiber and the high digestibility of the protein."

The Sucrene dairy feed "is decidedly less digestible than either flour middlings or gluten feed, and either of the two latter feeds would furnish digestible matter and especially digestible protein for less money than the Sucrene feed." Similar conclusions were drawn for the other sugar feeds tested.

Standard hominy feed, apparently, "has fully as much digestible matter as is contained in a like quantity of an average quality of corn meal. Hominy contains rather more protein and noticeably more fat than clear corn, and for some purposes may be considered a preferable feed."

Judged by composition and digestibility, oat middlings "would be a few per cent more valuable than average wheat-flour middlings for ordinary feeding purposes. It ought to make a valuable feed for young calves.

"It is evident from the analysis, from the digestion coefficients obtained, and from the retail price of the article ($26 to $28 a ton) that genuine buckwheat middlings is an economical source of dry matter and digestible protein."

The sorghum fed as a soiling crop was found to have had the same digestibility, according to the authors, as millet and corn fodder at a similar stage of growth. "The protein only seems to be less digestible than that contained in the other two fodders. Sorghum is eaten well by dairy cattle, is available just before corn is sufficiently mature to be at its best, and is considered a satisfactory addition to the list of soiling crops for Massachusetts."

When the smaller amount of molasses, 150 gm. per head daily, was consumed with 800 gm. of hay the results were somewhat contradictory and definite conclusions can not be drawn "other than to conclude that this quantity of molasses was well assimilated, without causing any serious digestion depression." When the larger amounts of molasses, 250 gm., were consumed with a like quantity of hay or with 600 gm. hay and 200 gm. gluten feed, a depression in the digestibility of other constituents of the ration was noted and it is intended to continue the work to secure additional data. From the results as a whole it is evident that "2,000 lbs. of Porto Rico molasses contain between 1,080 and 1,160 of easily digestible carbohydrates, and that its crude protein has little or no value as a source of nutrition.

"The gluten feed appears to have been thoroughly digested, showing higher coefficients than the average of previous trials."

It is claimed that the hulls of Sea Island cotton seed are thin and that it is not possible or profitable to thoroughly separate them from the meats. In general, the Sea Island cotton-seed meal was inferior in digestibility to high-grade meal.

"The fat in the low-grade meal is shown to be nearly all available, while the protein is somewhat less digestible than that contained in a high-grade meal; the chief difference, however, in the digestibility of the 2 grades is to be found in the total dry and extract matter, decidedly lower coefficients being secured from the low-grade meal containing a high fiber percentage. . . . The low-grade meal contains only about one-half as much of the most valuable ingredient (digestible protein) as does the high-grade meal. The former meal will likewise require considerably more energy for its digestion."

In the authors' opinion, the observed increased digestibility of protein of white wheat and feed barley over red wheat protein is probably due to the relatively higher protein contents of these two grains and consequently of the rations containing them. "It is believed that the protein in ordinary grains (maize, wheat, and barley) is equally and quite fully digested, providing it is fed in a ration having a ratio of 1:8 or less.

"In view of their composition and digestibility, it would seem as if there were no reason to expect any particular difference in the feeding effect of . . . wheat and corn. It is possible, however, that the energy required for the digestion of the wheat might be greater than that required to digest the corn. It is well known that poultry are particularly fond of corn and moderately so of wheat, but do not care especially for barley. This fact should not be overlooked in comparing the relative merits of corn, wheat, and barley for this class of stock."

The data for Blomo horse feed, which are reported, have been noted in a previous publication (E. S. R., 17, p. 283). The materials used in the digestion experiments were analyzed.

Digestion experiments with wethers, H. G. KNIGHT, F. E. HEPNER, and G. E. MORTON (*Wyoming Sta. Rpt. 1906, pp. 38–44*).—Noted from another publication (E. S. R., 18, p. 262).

Ration experiments with lambs, 1905–6, G. E. MORTON (*Wyoming Sta. Bul. 73, pp. 18, figs. 12*).—In the first of the feeding tests reported native hay fed with oats, corn, and barley meal, alone and supplemented with oil meal, was compared with alfalfa hay and corn, using 7 lots of 5 lambs each. In the 14 weeks covered by the test the gain on the native hay rations ranged from 12.8 lbs. per head when corn was fed to 17.4 lbs. with oats and oil meal. The smallest amount of grain per pound of gain, 5.75 lbs., was noted with the barley ration and the largest amount, 6.77 lbs., with the oats and oil meal ration, 6.54 and 5.74 lbs., respectively, of the hay being required in addition. In the case of the alfalfa hay ration 3.82 lbs. of corn and 5.84 lbs. of hay were required per pound of gain.

"None of the native hay rations were as satisfactory as corn and alfalfa.

"Hulled barley and native hay proved to be the most economical of the native hay rations.

"Oil meal, fed with native hay and grain, increases the cost of gain, although it produces slightly greater gains than native hay and grain without oil meal. When fed with corn and native hay, it produces enough greater gains to make the ration practically equal in cost to the native hay and corn ration, and the extra degree of fatness in the lambs brings a better price in the market."

In a comparison of corn and alfalfa hay with peas in the field, which was made with 2 lots of 100 lambs each, the average gain per head on the former ration was 31.24 lbs. in 14 weeks and on the latter 19.98 lbs., 6.82 lbs. of alfalfa and 2.92 lbs. of corn being required per pound of gain, as compared with the peas grown on five-eighths of an acre.

"Field peas, grazed off, showed returns approximately equaling the returns from feeding alfalfa and corn, with the peas valued at $8 per acre, alfalfa at $5 per ton, and corn at $1 per cwt.; although the alfalfa and corn lambs gained about one-half more than the pea lambs."

During shipment the lambs fed corn and alfalfa shrank 4.2 lbs. per head more than the pea-fed lambs.

Summary of lamb feeding, 1905–6, G. E. MORTON (*Wyoming Sta. Rpt. 1906, pp. 23–32*).—Noted above from another publication.

Growing hogs in western Nebraska, W. P. SNYDER (*Nebraska Sta. Bul. 99, pp. 32, figs. 9*).—A number of tests were undertaken to ascertain the most profitable methods of producing pork on alfalfa and to study the feeding value of grains commonly grown locally.

Using 10 lots of 12 to 30 pigs, 3 tests were made to compare varying amounts of grain (corn alone or with rye or shorts) as a supplement for alfalfa pasturage. The feeding periods varied from 63 to 119 days in length. The average daily gain ranged from 0.28 lb. on 0.5 lb. of corn per 100 lbs. live weight to 1.08 lbs. per head per day on a full ration of corn with rye during the latter part of the period. The greatest range in grain eaten per pound of gain, 1.21 to 3.36 lbs., and in average daily profit per pig, 1.3 to 3.6 cts., respectively, were also noted with these lots.

The relative merits of long and short feeding were tested by continuing one of the lots on the light grain ration (3 lbs. per 100 lbs. live weight) until the whole period covered 259 days. The average daily gain was 0.68 lb., the grain eaten per pound of gain 3.88 lbs., and the daily profit per pig 2.5 cts.

"A light grain ration is not the most economical for growing pigs, unless under peculiar circumstances, when alfalfa is abundant, grain very high in price, and market conditions warrant holding the hogs. It seems probable that 2 or more pounds of corn daily per each hundredweight of hogs is more profitable than a lighter ration.

"The cost of gain is not a reliable criterion of profit. A cheap gain may be so slow as to be unprofitable. Time, labor, and investment should be considered when reckoning profits. A full grain ration, though making the gain more costly, usually gives greater profits, because of the larger amount of business transacted in a given time with a given number of hogs."

Four tests covering 30 to 95 days were made with 7 lots of 10 to 29 pigs each to study different methods of feeding corn with alfalfa pasturage. On the alfalfa alone the average daily gain was 0.49 lb. per head and on corn alone in a dry feed lot 2.55 lbs., 4.31 lbs. of grain being required per pound of gain and the daily profit per pig being 7 cts. On corn and pasturage combined the greatest gain, 2.83 lbs. per head per day, was noted with one of the lots fed 3 lbs. of corn per 100 lbs. live weight, the grain eaten per pound of gain being 3.01 lbs. and the daily profit per pig 10 cts. A lot on the same kind of ration and one on a full corn ration with alfalfa each made an average daily gain of 1.6 lbs. per head.

"Mature hogs thin in flesh may be expected to gain about ½ lb. per head daily on alfalfa without grain.

"Mature hogs, fed corn in a dry lot while being fattened, required nearly one-half more grain to produce 100 lbs. gain, and gave a daily profit of 3 cts. less per hog than similar hogs running on alfalfa pasture."

When wet ground corn and barley were fed alone, with whole alfalfa hay, and mixed with cut alfalfa hay in a 91-day test with 6 lots of 10 pigs each, the smallest gain, 1.07 lbs. per pig per day, was noted with barley and cut alfalfa 3:1, and the largest gains, 1.26 lbs. and 1.27 lbs., with corn and cut alfalfa 3:1 and corn and alfalfa hay, respectively. The grain eaten per pound of gain ranged from 4.2 lbs. on the corn and cut alfalfa ration to 5.73 lbs. on barley alone, and the daily profit per pig from 2.2 cts. on the last-mentioned ration to 3.6 cts. on the corn and cut alfalfa 3:1.

In a comparison of corn, emmer, and barley with alfalfa hay, which was made with 3 lots of 20 pigs and covered 94 days, the average daily gains on the 3 grains were 1.02, 0.77, and 0.81 lbs. per head, respectively. With corn alone and with emmer and with barley 1:1, the average daily gains were 1.53, 1.35, and 1.45 lbs., respectively. Each lot contained 12 pigs and the test covered 42 days. Considering both the tests the grain eaten per pound of gain ranged from 4.62 lbs. with corn and barley to 6.18 lbs. with emmer, and the daily profit per pig from 1.3 cts. on emmer to 3.9 cts. in one of the tests on corn alone.

"For fattening hogs that have access to alfalfa hay, corn at 35 cts., barley 24 cts., and emmer 19 cts. should give about equal profits. Under these conditions, 4 bu. of barley are worth as much as 5 bu. of emmer.

"Where barley or emmer is fed to hogs it is more profitable to make the ration one-half corn than to feed emmer or barley alone."

Considering financial aspects the conclusion is drawn from the tests as a whole, that "conditions in western Nebraska are favorable to a large production of pork. In every test, where conditions were not peculiarly unfavorable, grain fed to hogs has returned much above the market price.

"Alfalfa may be fed with profit to growing or fattening pigs in almost any form so long as it does not make up too large a proportion of the ration. When cut and fed as one-quarter of the ration with ground corn, it materially reduced the cost of gains and increased the profits. . . .

"With sufficient good alfalfa, well stacked, mature hogs can be carried through the winter in fair condition, with 3 lbs. of corn per head per day, and if necessary with much less grain."

The damage done by the hogs to the alfalfa pastures is estimated by the author at one-half the crop or less.

"The number of hogs that may be pastured profitably on an acre depends very largely on the amount of grain fed. Probably from 6 to 8 hogs, under ordinary conditions, would be about the right number. This would allow enough alfalfa to grow to make 3 fair crops per year. The fields should be small rather than large, so that the part nearest the water and sheds will not be kept too close to the ground and that at the farther end of the field be left untouched.

"We have not observed satisfactory results with sows run on alfalfa without grain during the pregnant period, although very little grain is necessary for pregnant sows which are to farrow in the fall."

Poultry experiments, 1906–7, G. M. GOWELL (*Maine Sta. Bul. 144, pp. 145–186, pls. 6*).—The construction and operation of the station brooder houses, houses for laying and breeding hens, and trap nests are discussed, as well as the station methods of feeding young chickens, cockerels, growing pullets, and hens.

In the case of pullets it is stated that the method of dry feeding described in an earlier publication (E. S. R., 17, p. 388) has given satisfactory results.

"The labor of feeding is far less than that required by any other method. The birds do not hang around the troughs and overeat, but help themselves, a little at a time, and range off, hunting, or playing and come back again, when so inclined, to the food supply at the troughs. There is no rushing or crowding about the attendant, as is usual at feeding time, where large numbers are kept together."

In the case of hens the average amount eaten per bird during the last year approximated 90 lbs. grain and meal mixture, 4 lbs. oyster shells, 2.4 lbs. dry cracked bone, 2 lbs. grit, 2.4 lbs. charcoal, and 10 lbs. clover. The cost of these materials was about $1.45 and the average egg production 144 per hen.

The relative value of green alfalfa and clover was studied, a peck of the finely chopped material per 100 hens being fed twice a day. The hens "evidently relished the clover better than the alfalfa, but the alfalfa has the advantage of being ready to use before the clover has made growth enough to cut. . . .

"Clover is the most satisfactory green food that the station has used and the expense of growing it need not be great, as small areas will furnish enough for liberal feeding. The supplies of it should be constant, and that there may be no shortage between the first and second crops in the regular clover fields, small tracts of land can be seeded on the frozen ground early in the spring and the clover be large enough for use when needed to keep good the supply.

"Dwarf Essex rape has also been satisfactorily used for green food for growing chickens in the open field. . . .

"Experience with the wide, open front house is in favor of yards on the north rather than on the south side of the building."

When dry oat hay was used instead of oat straw for bedding it was found that the hens ate considerable quantities of the material, which was decidedly laxative.

"Long ago we learned that we must not feed mangles too freely, because of their laxative tendencies, but there was no thought that the dry hay, although made from young plants, was comparable with the crisp, juicy mangles."

A test of the relative merits of like amounts of whole and cracked corn as part of the ration was made with 10 lots of 100 birds each. The corn was mixed with wheat 1 : 1 and was fed scattered evenly over the floor. On the whole corn ration the average egg production in 6 months was 77.8 eggs per hen and on the cracked corn ration 75.9 eggs. Nineteen of the hens fed whole corn and 29 of those fed cracked corn died during the test.

"There is nothing in the results that leads to the conclusion that it is necessary or advisable to crack the corn fed to hens kept for laying eggs. The slight differences in the average yields of the birds in the 2 classes should not be interpreted as meaning that cracked corn is inferior to whole corn. Neither do the somewhat greater losses of birds on the cracked corn ration indicate that the cracked corn was injurious."

Unsatisfactory results were noted when hens were kept in winter in houses sprayed with lice exterminator. The egg yield was materially diminished and the hens were in poor condition for some time. The author believes that such preparations should not be used too freely in cold weather.

"The most unsatisfactory feature of this experience was that the treatment did not kill the lice or materially lessen their numbers. It was only when, later, the birds were individually treated with the tobacco dust and insect powder, worked in among the feathers, that the lice were nearly exterminated.

"The insides of the buildings are treated with these liquid preparations in warm weather, so that the woodwork may be obnoxious to the lice and prevent their lodging there. For this purpose they are satisfactory, but our experience with them shows plainly that any material, with odors sufficiently strong to penetrate the feathers and kill the lice on the bodies of live hens, will prove destructive to the hens themselves."

Poultry experiments, W. P. BROOKS, E. S. FULTON, and E. F. GASKILL (*Massachusetts Sta. Rpt. 1906, pp. 60–64*).—Continuing earlier work (E. S. R., 18, p. 268), wheat and corn supplemented by animal meal were compared, both rations having a high content of fat and ash and a low crude fiber content. The deficiency in fat in the wheat ration was made up by adding corn oil. On the wheat ration with a nutritive ratio of 1 : 4.57 the egg production for the first period, January 25 to April 28, was at the rate of 48 eggs per day per 100 hens, and on the corn ration with a nutritive ratio of 1 : 6.5, at the rate of 54 eggs per day, the cost of feed per egg being 0.96 ct. and 0.73 ct., respectively. For the second period, April 28 to September 5, the wheat ration produced at the rate of 37 eggs per day per 100 hens and the corn ration 39 eggs, the cost of feed per egg being respectively 1.01 and 0.82 cts. The results are in accord with those previously obtained.

When wheat and corn were compared in similar rations except that milk albumen was the animal feed used, the average egg production on the wheat ration during the winter period was at the rate of 49 eggs per day per 100 hens and during the summer period 35 eggs, and on the corn ration during the two periods 47 and 46 eggs, respectively. On wheat the cost of egg production in both periods has been 0.96 ct. per egg and on the corn ration 0.86 ct. in the winter period and 0.74 ct. in the summer period. In general, the results support the conclusions previously drawn.

In the third test, oats and oat feed, grains with high crude fiber content, were compared with rice, in which this constituent is low, the rations as a whole having low protein, high ash, and high fat content. During the winter period the egg production on oats was at the rate of 32 eggs per day per 100 hens and on rice 46 eggs, and during the summer period on the oat ration 32 eggs and on the rice ration 37 eggs. The authors state that the cost of the feed eaten per egg produced was greater on the rice than on the oat ration. The results obtained are in accord with those of previous years, namely, that a large proportion of crude fiber in a ration for laying fowls seems to be very unfavorable to satisfactory egg production..

Range management, J. S. Cotton (*U. S. Dept. Agr. Yearbook 1906, pp. 225–238, pl. 1*).—The present condition of the western ranges and the need for avoiding overgrazing, resting the land, alternation of pastures, reseeding ranges, conservation of water, and other methods of range improvement are discussed, as well as the need for improving the grade of stock and similar topics.

In order to secure the greatest returns from land, it will be necessary in the future, in the author's opinion, to raise feed for wintering cattle.

"Of the different cereals that can be used for hay, rye will probably prove to be the surest to yield a good crop over the greatest area of country. . . . Beardless barley is another excellent crop to grow for grain hay. . . . In some sections of the country, as in the Dakotas, durum wheat will produce a considerable amount of forage in the more favorable years. In other sections many of the farmers seem to be well pleased with spelt. These last two plants are not so desirable for stock as some others on account of their heavy beards."

There is a noticeable movement toward farming range lands.

"Present tendencies indicate that the range-stock industry of the future will be confined to those regions that are too rough for cultivation or too arid for the successful growth of crops. Except in the high mountain regions, where the grazing season is very short, or in the desert areas, where, on account of the scarcity of water, grazing can be carried on only during the winter months, the grazing will eventually be carried on in inclosed fields or on definitely assigned tracts. The stockmen will endeavor to get bodies of land large enough to support their stock, either by purchase, leasing, or, in case the homestead act should be amended to fit range conditions, by homesteading. Many living in close proximity to forest reserves will secure grazing permits, allowing them to run stock in these areas during the summer season. Wherever possible these men will raise enough feed to carry their stock safely through the winter season."

Foreign restrictions on American meat, F. R. Rutter (*U. S. Dept. Agr. Yearbook 1906, pp. 247–264, fig. 1*).—The author has summarized the laws and regulations in force in the principal foreign countries regarding the importation of American meat and meat products and similar data, believing that a knowledge of present conditions is necessary if trade is to be extended.

"There is no reason why the stricter control now exercised [in the United States] over all processes of slaughtering and preparation of meat should not induce the leading foreign governments to modify the more serious restrictions and admit American meat on freer terms. Such action is more feasible because treaty relations among European countries are still undergoing revision, and within many of those countries a strong demand has sprung up for the freer admission of foreign cattle and meat."

Some recent studies on heredity, E. B. Wilson (*Jour. Amer. Med. Assoc., 48 (1907), No. 19, pp. 1557–1563*).—This discussion of recent experiments in the study of heredity is of interest in connection with animal breeding.

Classification for American carriage horses (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 113, pp. 4*).—The Bureau of Animal Industry, in cooperation with experiment station officials, is attempting to establish a breed of American carriage horses which will come true to type. In order to accomplish this result it was thought desirable to establish also classes for such horses at State and National fairs. The present classification was adopted and is recommended to fair associations in order to make the qualifications for carriage horses at different fairs as nearly uniform as possible.

Relative proportions of the sexes in litters of pigs, G. M. Rommel (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 112, folio*).—From data gathered for 1,477 sows representing 8 breeds, it appeared that the average size of a litter was 9 pigs in round numbers, made up of boars and sows in about equal proportion, the ratio being 201 of the former to 200 of the latter.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Dairy farming, J. Michaels (*Clemson College, S. C.: Author, 1907, pp. 212, figs. 67*).—The author states in his preface that he has endeavored to arrange in a concise and systematic form the essential facts relating to the science and practice of dairy farming. The book consists of two parts, one dealing with the dairy herd and the other with milk and its products. It is written in plain language so that it may be used by the farmer not versed in science as well as by the dairy student. The technical terms used are defined.

Opportunities for dairying (*U. S. Dept. Agr. Yearbook 1906, pp. 405–428*).—Following brief general notes by W. H. Dexter, G. M. Whitaker discusses dairying in New England, B. D. White dairying in the North Central States, B. H. Rawl dairying in the South, and E. A. McDonald dairying on the Pacific coast. The advantages and disadvantages of the industry in each of the regions mentioned are clearly set forth.

The dairy cow, P. Dechambre (*La Vache Laitière. Paris: Libr. Sci. Agr., 1907, pp. XI+280, figs. 23*).—This volume is a part of a series on agriculture and agricultural science. It deals with the formation of milk, the various dairy breeds, the care and feeding of cows, milking, and some of the more common diseases of cows.

The production, care, and uses of milk (*Ontario Dept. Agr. Bul. 160, pp. 16*).—This bulletin is made up of a number of brief popular articles on subjects indicated by the title.

Development of dairy shorthorns, R. T. Archer (*Jour. Dept. Agr. Victoria, 5 (1907), No. 6, pp. 348–357, figs. 6*).—Notes are given on the value of shorthorns for dairy purposes and records of 40 cows for 1 to 6 lactation periods are reported. The average yield of 13 3-year-old heifers for 1 year was 583 gallons of milk and 289.9 lbs. of butter.

Record of the station herd, 1905–6, J. L. Hills (*Vermont Sta. Rpt. 1906, pp. 351–355*).—Tabulated records of the station herd from November 1, 1905, to October 1, 1906, are published.

The effect of age on the yield and quality of milk, J. L. Hills and E. Kibby (*Vermont Sta. Rpt. 1906, pp. 339–350*).—Annual records of 99 cows secured at the station during a period of 10 years were studied to show what effect advancing age has upon the yield and quality of the milk. The principal conclusions reached are summarized as follows:

"*Milk flow.*—At the outset and until the average cow was 7 years old the general tendency was for the flow to increase in volume. That of her eighth year tended to be lower than that of the seventh, much lower than that of the ninth, and to resemble that of the tenth year. No cause was found nor is stress laid upon the sag. From the ninth year the trend was downwards.

"*Total solids.*—In 3 cases in 46 the trend from the first figure to those following is upwards; in 10 cases the change is nil; in 32 cases the trend is downwards.

"*Fat.*—In 3 cases in 46 the trend from the first figure to those following is upwards; in 14 cases the change is nil; in 29 cases the trend is downwards.

"*Solids-not-fat.*—In 9 cases in 46 the trend from the first figure to those following is upwards; in 14 cases the change is nil; in 23 cases the trend is downwards."

Similar studies made elsewhere are summarized. The differences from one year to another were not striking. The author does not believe that the effect of advancing years upon milk quality is profound enough to be of importance until old age becomes imminent.

Home-grown protein v. purchased protein; distillers' grains v. gluten feed; summer silage v. soiling, G. A. Billings (*New Jersey Stas. Bul. 204, pp. 28*).—Three feeding experiments are reported.

In the first experiment alfalfa hay was compared with purchased feeds as a source of protein. Two lots of 4 cows each were fed for 2 periods of 60 days each. When alfalfa hay was the sole source of protein the average daily yield of milk per cow was 20.41 lbs. and the yield of fat 0.876 lb. The cost to produce 100 lbs. of milk was 94.36 cts. and the cost of 1 lb. of butter 18.82 cts. When protein was supplied by distillers' grains, wheat bran, and cotton-seed meal the average daily yield was 24.63 lbs. of milk and 1.068 lbs. of fat. The cost to produce 100 lbs. of milk and 1 lb. of butter was respectively 83.72 and 16.55 cts. The conclusion is drawn from the results of this experiment that alfalfa and other home-grown protein feeds may well furnish a large part but not the whole of the protein required to balance rations in which silage or other roughage of like character is used.

In the second experiment including 4 cows and lasting 60 days, dried distillers' grains were compared with gluten feed in quantities making the nutritive ratios practically the same. Of the gluten feed ration the average daily yield per cow was 23.31 lbs. of milk and 0.994 lb. of fat. The cost of production per 100 lbs. of milk was 86.40 cts. and of 1 lb. of butter 17.36 cts. When distillers' grains were fed the average daily yield was 23.85 lbs. of milk and 1.026 lbs. of fat. The cost of producing 100 lbs. of milk was 80.50 cts. and of 1 lb. of butter 16.04 cts.

Summer silage was compared with soiling, the experiment including the herd of 25 cows and the feeding periods being 3 weeks for each ration. The average daily yields of milk per cow on wheat forage and corn silage were, respectively, 22.35 and 21.71 lbs., the average yields of fat 0.953 and 0.929 lb., the cost of producing 100 lbs. of milk 74.72 and 74.80 cts., and the cost of producing 1 lb. of butter 15.01 and 14.99 cts. The shrinkage on the silage following the forage was, therefore, about 3 per cent, which was less than the average shrinkage for the herd at the same season in previous years. The silage ration, therefore, more than maintained the yield of milk obtained with the forage crop ration.

Feeding trials with cows, J. L. HILLS (*Vermont Sta. Rpt. 1906, pp. 302–336, 356–384*).—The feeding trials conducted during the year were made with 44 cows, lasted 25 weeks, and included tests of silage made from frosted and from frozen corn, tests of alfalfa hay meal, and a further study of the experimental error involved in feeding trials by the alternation method.

The work is summarized as follows:

"Silages made from mature frosted and from mature frozen corn, compared with those made from immature unfrosted and frosted corns, contained from 6 to 15 per cent more dry matter. The effect of frost was slightly to depress the total solid and fat yields of milk, not to exceed 3 per cent, however, in any case. The milk yields were but slightly changed, with a tendency to depression. This minor loss is a negligible quantity as compared with the increased growth of digestible dry matter arising from the greater maturation of the crop. No ill effect was observed on the butter, although no special trial of the matter was made. Silage from frozen corn is said to keep well in a silo. The testimony of these considerable and varied trials would seem to warrant one in advising that frost risks be run in order to gain a greater maturation, when the corn has not reached a desired stage of ripening at the normal time of harvest, provided the crop is to be ensiled.

"An alfalfa meal ration made less milk and butter, carried less fertilizing value, and was fed at a loss, as compared with a wheat bran ration, the meal costing $27 and the wheat bran $18.50. Had each cost alike the former would still have been outclassed. An alfalfa meal ration made one-seventh less milk, one-sixth less butter, and the ration containing it carried one-sixth less plant food value than did one containing distillers' dried grains. It is utterly outclassed at equal prices.

"Protena, a proprietary article, the basis and principal constituent of which is alfalfa meal, made as much milk as did a mixture of wheat bran, cotton-seed and linseed meals, but 7 per cent less butter. The Protena ration carried but four-fifths the plant food content of its competitor, and was outclassed when financially compared.

"It does not seem that alfalfa products can be considered economic feeds at present, unless sold at $18 or less.

"Experimental error, when the alternation system is properly employed, is a negligible quantity."

Prickly pear and sotol as winter forage (*Estac. Agr. Expt. Ciudad Juárez, Chihuahua, Bol. 6, pp. 18*).—The results of feeding experiments with 15 cows indicated that under Mexican conditions satisfactory use may be made of species of Opuntia and of *Dasylirion wheeleri* for feeding cows during the winter months.

Cotton-seed meal and corn silage as a ration for dairy cows, J. MICHELS and J. M. BURGESS (*South Carolina Sta. Bul. 131, pp. 11*).—Ten cows were fed a ration consisting exclusively of cotton-seed meal and a good quality of corn silage for a period of over 5 months with very satisfactory results. The cows yielded more milk and butter fat than during any corresponding period in previous years. No bad effects were observed even when the meal and silage were fed separately. It is, therefore, believed that cotton-seed meal to the extent of 5 to 6 lbs. per cow daily and well-matured corn silage constitute an excellent ration for milch cows. The good results obtained by the authors in feeding cotton-seed meal and silage are attributed in a large measure to the fact that the silage was made from well-matured, well-eared corn.

Milking machines, H. H. DEAN and S. F. EDWARDS (*Ontario Dept. Agr. Bul. 159, pp. 24*).—The first part of this bulletin, by Professor Dean, gives the results of considerable experience with milking machines, from which the author draws the following conclusions:

"In the comparative tests made of hand and machine milking for short periods the results were in favor of hand milking in all tests except one.

"When the machine was compared with inexperienced hand milking there was not so much difference between the results got from hand and machine milking, showing that under certain circumstances the machine might be equal to hand milking for at least a short period of time.

"The general tendency was for the cows to go dry sooner than they were accustomed to do with hand milking. This was more particularly the case with the older cows. However, this is a point not easily solved, as cows vary in this respect from year to year.

"Some of our young cows have given very good results with the machine, indicating that it may be possible to breed and train cows which will give fairly good results under this system of milking, though they are not likely to be so good as if trained to hand milking.

"Special care needs to be exercised in the cleaning of the machine, otherwise the milk is liable to be tainted. Simply sucking water through the parts is not sufficient. All parts of the machine that come in contact with the milk must be thoroughly scalded or steamed, at least once a week, and for good results this should be done daily.

"On average farms, where 10 to 25 cows are kept, we do not believe that it would pay to install a milking machine at present. On farms where 50 to 100 or more cows are kept, and where labor is very expensive and difficult to get, and where the owner of the cows is not so particular about maximum yields from individual cows, the milking machine is worthy of careful consideration. However, we do not consider the machines at present on the market as anywhere near perfection, and we look for great improvement in them during the next few years."

The second part, by Professor Edwards, gives the results of bacteriological tests of machine-drawn and hand-drawn milk. When strict sanitary precautions were observed, milk obtained in the 2 ways showed practically the same average bacterial content.

The effect of freezing milk on creaming and churning and upon the quality of the butter, J. L. HILLS and E. L. KIRBY (*Vermont Sta. Rpt. 1906, pp. 337–339*).—In experimental work at the station the skimming of milk was not affected by freezing when the milk was properly warmed before running through the separator. The ripening of cream and the completeness of churning were also unaffected by freezing. A slight difference in the quality of butter made from frozen and normal milk was considered almost negligible.

Report of Swedish butter exhibits, 1906 (*Meddel. K. Landtbr. Styr. [Sweden], 1907, No. 1 (120), pp. 1–37*).—The report contains the usual information as to the examinations and scorings of Swedish export butter, conducted by a committee of the Swedish agricultural department during 1906.

During the year, 552 different creameries took part in the exhibits, the total number of tubs of butter scored being 2,230. These were in nearly all cases examined for water content, refractive index, and volatile fatty acids in the butter fat. The percentage of water in the butter ranged between 9.4 and 19 per cent for the individual tubs, and between 11.6 and 16.6 per cent, an average of 13.5 per cent, for the different creameries. The refractive index of the butter fat varied from 48.2 to 54.3, about 90 per cent falling between 50 and 53. The Reichert number ranged between 26.6 in the summer and 32.6 in the winter, with averages of 30.1 cc. for the summer, 30.5 for the fall, and 30.9 for the winter series. About 90 per cent of the creameries pasteurized their milk or cream. Pure cultures were used exclusively by 55 per cent of the creameries, at times by 18 per cent, while 22 per cent used buttermilk starter, and about 8 per cent made sweet-cream butter.—F. W. WOLL.

Essentials of milk hygiene, C. O. JENSEN, trans. and amplified by L. PEARSON (*Philadelphia: J. B. Lippincott Co., 1907, pp. 275, figs. 24*).—This book has been well translated and much improved by the additions made by the translator. It covers quite fully the whole subject of the sanitary supervision of the production, handling, and sale of milk and has been well adapted to American conditions.

Preservation of cow's milk, E. VON BEHRING (*Behringswerk Mitt., 1907, No. 2, pp. 25–38*).—A mixture of formaldehyde and hydrogen peroxid is considered by the author the best preservative of milk intended for human consumption. The article contains a few artificial digestion experiments with heated milk, but is mainly an argument in favor of the use of formaldehyde in milk under certain conditions.

A plan for improving the quality of milk and cream furnished to New Hampshire creameries, I. C. WELD (*New Hampshire Sta. Bul. 132, pp. 59–67, figs. 6*).—The author advocates the grading of cream and the paying of patrons accordingly. Such a system was put into operation at the New Hampshire College creamery July 1, 1906. The points allowed for a perfect score were as follows: Flavor 50, acidity 25, and condition 25. The scores for the milk of 25 patrons ranged from 77 to 95.

The bulletin contains a description of the apparatus and methods employed in determining the quality of milk and cream.

"The system of scoring or grading milk or cream and grading the price paid creamery patrons for butter fat according to the quality or condition of the milk or cream from which that fat is obtained would seem to be eminently just to the producer as well as to the creamery. While a part of the work of grading can be done by the use of tests which give results directly expressed by figures, other parts of the work are dependent solely upon the good judgment, ability, and honesty of the person who has the work in charge."

The Copenhagen milk supply company (*La Société Laitière d'Approvisionnement de Copenhague. Copenhagen, 1906, pp. 47, pls. 3*).—This is an authoritative account of the organization and work of the Copenhagen milk supply company, published on the occasion of the International Exposition at Milan in 1906.—F. W. WOLL.

Milk supply of Copenhagen, HOLLMAN (*Molk. Ztg., 21 (1907), No. 27, pp. 749–752*).—This article contains considerable statistical, chemical, and bacteriological data concerning the milk supply of Copenhagen.

Hemolytic substances in milk, M. PFAUNDLER and E. MORO (*Ztschr. Expt. Path. u. Ther., 4 (1907), No. 2, pp. 451–469*).—Intermediary bodies capable of producing hemolysis were not found in the several kinds of milk examined. Hemolytic complements, however, were found in the milk of the cow, goat, and guinea pig.

Variations in the chemical composition of the milk of tuberculous cows with and without mammary lesions, MOUSSU and MONVOISIN (*Compt. Rend. Soc. Biol. [Paris], 43 (1907), No. 26, pp. 156–158*).—The milk of cows affected with tuberculosis showed a diminution in acidity varying in proportion to the extent of the mammary lesions. In cases showing no mammary lesions the acidity was 0.08 per cent. With advanced lesions in the udder the acidity was still further reduced, being as low as 0.012 per cent. This variation in acidity from a normal of 0.14 to 0.20 per cent is directly opposite to that found in ordinary mammitis.

The total nitrogen was increased, the amount being sometimes double that in normal milk.

The fat showed a progressive diminution and became as low even as 0.15 per cent. The sugar was likewise reduced and occasionally was entirely absent.

The authors observed a lowering in the index of refraction, but no change in the freezing point, the latter being attributed to an increase in the amount of sodium chlorid.

The bacteriolytic alexin of milk, E. Moro (*Ztschr. Expt. Path. u. Ther., 4 (1907), No. 2, pp. 470–479*).—In experiments with the typhoid bacillus, raw cow's milk showed bactericidal properties. This was not true of the filtrate from the milk. Heating the milk for ½ hour at 56° C. destroyed its bactericidal properties. Milk freed from leucocytes by centrifuging still possessed an unfavorable influence upon the growth of the typhoid bacillus. Similar results were obtained with human milk.

Concerning the identity of the casein of different species of animals, R. Burow (*Beiträge zur Entscheidung der Frage, ob die Caseine verschiedener Tierarten identisch sind. Inaug. Diss., Univ. Basel, 1905, pp. 28*).—The elementary composition of the casein of milk from cows, goats, and guinea pigs was found to be practically identical. The average in round numbers was as follows: Carbon, 53; hydrogen, 7; nitrogen, 15.5; sulphur, 0.7; phosphorus, 0.8; and oxygen, 23 per cent.

The chemistry of milk and milk products in 1906, M. Siegfeld (*Chem. Ztg., 31 (1907), Nos. 56, pp. 701, 702; 57, pp. 714, 715*).—A review of the literature of this subject during 1906 with 126 references.

Report of the chemist (division of foods and feeding), J. B. Lindsey (*Massachusetts Sta. Rpt. 1906, pp. 82–95*).—This part of the report on the chemical work of the station includes statements concerning the examinations made of water and feeding stuffs, studies made of analytical methods, the results of inspection of dairy apparatus, and the testing of pure-bred cows. An outline is also given of the chemical work completed and of that in progress. Of the 2,457 pieces of dairy glassware examined 763 pieces, or 31.05 per cent, were condemned.

The creamery inspection law, C. H. Jones (*Vermont Sta. Rpt. 1906, pp. 298, 299*).—During the 7½ years that this law has been in force the station has tested 53,875 pieces of Babcock glassware, finding 890, or 1.65 per cent, incorrect.

National association of dairy instructors and investigators (*Illinois Sta. Circ. 111, pp. 59, figs. 3*).—This circular gives the proceedings of a meeting of dairy instructors and investigators held at the University of Illinois, July 17, 1906, at which time an association known as the National Association of Dairy Instructors and Investigators was organized. The following subjects were discussed: The manufacture of condensed milk, by O. F. Hunziker; a plan for the registration of dairies leading to the improvement of market milk, by C. B. Lane; city milk supply, by J. M. Trueman; difference in efficiency of dairy cows, by W. J. Fraser; some hand separator problems, by C. H. Eckles; pasteurization of hand separator cream for making butter, by C. E. Lee; benefits to be derived from educational butter contests, by B. D. White; milking machines, by H. H. Dean; advantages of the organization of dairy instructors and investigators, by E. H. Webster; opportunities for research work in the manufacture of dairy products, by C. F. Doane; how shall we conduct feeding experiments with dairy cows? by B. E. Carmichael; dairy instruction, by H. E. Van Norman; soft cheese problems, by C. Thom; reaching the farmer, by E. S. Guthrie; and testing dairy herds, by H. A. Hopper.

The preparation of unfermented apple juice, H. C. Gore (*U. S. Dept. Agr. Yearbook 1906, pp. 239–246, fig. 1*).—This article gives the results of experimental work in preparing unfermented apple juice. The method evolved consists in clarifying the juice by passing it through a centrifugal cream separator, bottling or putting in cans, carbonating if desired, and sterilizing by heating at about 70° C. for one-half hour. The composition of the juice was not appreciably affected by the process.

Studies on apple juice, H. C. GORE (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 1112–1119*).—Chemical work carried on in connection with the above investigations is here reported. Analyses are given of (1) juices of cull apples, (2) juices from the cider mill at various times during the season, (3) juices of several standard varieties of apples grown in Nebraska, (4) fresh and fermented juices of summer apples, and (5) juices of decaying apples.

VETERINARY MEDICINE.

Handbook of forensic veterinary science, B. MALKMUS (*Handbuch der Gerichtlichen Tierheilkunde. Hannover: M. & H. Schaper, 1906, pp. XV+687*).—This constitutes a comprehensive treatise on the legal position and duties of the veterinarian as based upon German laws. The subjects discussed in the volume include guarantees, deceit, excessive charges, and other illegal dealings in connection with the sale or transfer of domestic animals.

The chief and secondary defects of domestic animals from a legal standpoint are defined and notes are given on the pathological conditions which determine these defects.

Veterinary science in its relation to agriculture, L. J. BLENKINSOP (*Transvaal Agr. Jour., 5 (1907), No. 19, pp. 599–603*).—The author briefly refers to the great losses caused by animal diseases in various parts of the world in connection with a statement of the economic importance of veterinary science in the further advancement of agriculture.

A new feeding method and its relation to veterinary science, J. J. WESTBROEK (*Tijdschr. Veeartsenijk., 34 (1907), No. 8, pp. 485–516*).—According to the author the common belief in the necessity of salt in the diet for domestic animals is not well founded. It is argued that the addition of salt to the ration causes more or less serious disturbances in the normal osmotic processes, at times greatly changing the composition of the tissues and fluids of the animal body. Tables are presented showing the striking modifications which common salt may produce in the amount of potash, sodium, magnesium, lime, and other minerals in the flesh of hogs and cattle.

The author claims that common salt, when added to the ration, gradually replaces the salts which should be present in animal tissues and causes pathological conditions.

A consideration of some of the modern theories in relation to immunity, P. C. FREER (*Philippine Jour. Sci., 2 (1907), No. 2, pp. 71–81*).—A critical review is given of the various theories which have been proposed in explaining immunity, particularly from a chemical standpoint.

The mechanism of nonbactericidal immunity, E. WEIL (*Arch. Hyg., 61 (1907), No. 4, pp. 293–323*).—If the complement is removed from the body cavity of guinea pigs by precipitation, the immune serum of fowl cholera becomes inactive and the course of infection in the absence of the complement is much more rapid than is the case in normal animals. The function of the complement can apparently be performed by leucocytes if such be present. The author was unable to demonstrate any combination of immune serum with fowl cholera bacilli in the animal body. It was also impossible to determine the action of the immune serum upon the leucocyte. The author maintains that since the complement, which is so important an agent in immunity, does not exercise a bactericidal function it must possess some other function.

The prospect of a practical method of preventive vaccination against foot-and-mouth disease, M. Casper (*Berlin. Tierärztl. Wchnschr., 1907, No. 20, pp. 399–405*).—The methods which have thus far been proposed for preventive vaccination against foot-and-mouth disease are classified by the author into 4 groups in which the following materials are used: Blood, serum, or milk of animals which have recovered from the disease; the blood or serum of artificially immunized animals; virulent or attenuated lymph, and blood or serum combined with the lymph of artificially immunized animals. The technique of each of these methods is described and notes are given on the results thus far obtained from their application. In the author's opinion the strict maintenance of quarantine measures must still be considered as the chief means of preventing the spread of foot-and-mouth disease for the reason that no efficient and practical method of preventive vaccination has been devised.

Veterinary department (*Massachusetts Sta. Rpt. 1906, pp. 206, 207*).—A pathological collection is being made and information is being disseminated among farmers regarding important diseases of live stock.

Stock diseases, F. Clutterbuck (*Jour. Dept. Agr. West. Aust., 15 (1907), No. 4, pp. 235–244*).—Brief mention is made of some of the more important animal diseases, including lung worms of sheep, tuberculosis, pleuro-pneumonia, and hog cholera, the means by which they are spread, and the importance of meat inspection in locating centers of infection.

Some notes on the prevalence of the different contagious diseases at present existing in the Transvaal, R. H. Williams (*Transvaal Agr. Jour., 5 (1907), No. 19, pp. 673–676*).—Brief statements are made regarding the present status of East-coast fever, sheep scab, glanders, tuberculosis, hog cholera, etc.

Notes from practice, E. Diem (*Wchnschr. Tierheilk. u. Viehzucht, 51 (1907), No. 22, pp. 421–425*).—A brief account is given of petechial fever following upon strangles in horses. Striking success was had in the treatment of pulmonary gangrene with potassium iodid. Short notes are also given on peritonitis in cattle and horses, cerebral hemorrage, and vaginitis.

Medicinal treatment of infectious diseases, Gmeiner (*Deut. Tierärztl. Wchnschr., 15 (1907), No. 22, pp. 305–309*).—A general account is given of the use of medicinal agents in counteracting infectious diseases. Among these substances mention is made of the various alkaloids and the active principles of digitalis, strophanthus, and camphor.

Operative treatment of actinomycosis, Dorn (*Wchnschr. Tierheilk. u. Viehzucht, 51 (1907), Nos. 17, pp. 321–326; 18, pp. 341–347; 19, pp. 361–366*).—A detailed record is given of the results noted from the operative treatment of a number of cases of actinomycosis. The author concludes that it is possible to remove the actinomycotic tissue so thoroughly that the disease will not recur. In this operation it is recommended that the skin be removed over the whole tumor together with the tumor and that care be exercised in the operation not to produce any pockets in the incised tissue. An antiseptic application should be made after the operation, and the pressure produced in drawing the edges of the skin together over the wound serves to establish drainage until healing takes place.

Trypanosome infection through the mucous membrane of the alimentary tract, W. L. Yakimoff and N. Schiller (*Centbl. Bakt. [etc.], 1. Abt., Orig., 43 (1907), No. 7, pp. 694–702*).—In experimental rodents it was shown that infection with trypanosomes might take place through the mucous membrane of the alimentary canal. Infection was favored by the diminution of the peristaltic motion of the intestines, while neutralizing the gastric juice appeared to have no influence upon the process of infection. The same may be said for fasting preceding the feeding of animals upon virus containing trypanosomes.

Notes on baleri, L. Cazalbou (*Rev. Gén. Méd. Vét., 9 (1907), No. 106, pp. 564–572, figs. 2*).—The blood parasite of this disease was found in horses in conjunction with *Trypanosoma brucei.* It is believed, however, to be a distinct species. Baleri is a trypanosomiasis of horses characterized by repeated and violent attacks of fever, swellings in various parts of the body, pronounced injection of the conjunctiva, and general emaciation.

The trypanosomiases of the Upper Nile, A. Laveran (*Ann. Inst. Pasteur, 21 (1907), No. 5, pp. 321–356, figs. 3*).—The symptoms and pathological anatomy of souma and baleri are described in detail, and notes are given on *Trypanosoma cazalboui, T. pecaudi,* and *T. soudanense.* Souma chiefly affects horses, mules, and cattle, while most laboratory animals appear to be immune. Baleri is most commonly observed in horses, cattle, sheep, and goats. The disease due to *T. soudanense* has not received a specific name, but affects goats, sheep, dromedaries, dogs, and various other animals: Notes are given on a number of biting flies which may be concerned in the transmission of this disease.

The trypanosomiasis in French Guinea, G. Martin (*Ann. Inst. Pasteur, 21 (1907), No. 5, pp. 357–383, figs. 11*).—The trypanosomiasis commonly observed in mules and cattle in French Guinea and in other regions along the Niger is due to *Trypanosoma dimorphon.* The biology of this organism is described, and notes are given on the results obtained from inoculation experiments with this blood parasite. Mention is also made of the biting flies of the region which may be concerned in the transmission of the disease.

A study of rabies, C. Fermi (*Arch. Path. Anat. u. Physiol. [Virchow], 188 (1907), No. 3, pp. 428–469*).—In this study particular attention is given to the susceptibility of rats and mice to rabies virus and the virulence of fixed rabies virus in different laboratories. In experiments with rats and mice it appeared that death took place nearly as soon after subcutaneous as after subdural inoculation.

Is the cerebro-spinal fluid of rabid animals virulent? B. V. Fursenko (*Arch. Vet. Nauk [St. Petersb.], 36 (1907), No. 2, pp. 99–103*).—A series of inoculation experiments was made by the author for the purpose of determining whether the cerebro-spinal fluid of dogs affected with rabies contained the virulent virus of the disease. The results were negative in all cases and indicate that this fluid does not contain the virus.

The attenuation of fixed rabies virus necessary to render this material innocuous for rats and mice, C. Fermi (*Centbl. Bakt. [etc.], 1. Abt., Orig., 43 (1907), No. 7, pp. 709–713*).—Inoculation experiments carried out on 71 rats and mice of different species indicate that fixed virus attenuated for 3 days according to the Pasteur method is perfectly harmless for these animals. In every case the experimental animal remained alive and showed no evidence of infection.

In further experiments by the author it appeared that the virulence of rabies virus from wolves is greater than that from other animals.

The treatment of rabies with radium, A. Calabrese (*Ann. Inst. Pasteur, 21 (1907), No. 2, pp. 156–160*).—This article is largely of a controversial nature, in which the position is taken that the results announced by Tizzoni and Bongiovanni on the effect of radium are by no means always to be observed. According to the investigations of the author virus is not always destroyed by radium rays, and the tissues immediately subjected to the action of the rays may be seriously affected.

Persistence of rabies virus in the saliva of dogs after recovery from the disease, P. Remlinger (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 15, pp. 800–803*).—It has already been shown that the saliva of dogs may contain rabies virus before the external symptoms of the disease appear. In the observations reported in the present paper the author noted that the saliva may remain virulent for several days after complete recovery has taken place.

The mode of absorption of tetanus toxin, P. Cernovodeanu and V. Henri (*Compt. Rend. Soc. Biol.* [*Paris*], *62* (*1907*), *No. 15, pp. 812–815*).—In a study of the absorption of tetanus toxin it was found that the movement of the toxin could be checked as effectively by severing the blood vessels of the leg in which the injection was made as by severing the nerves. If the blood vessels are severed and the muscles of the thigh ligatured, large doses of tetanus toxin may be injected into the extremity of the leg without causing tetanus. The toxin in such cases, however, remains virulent and the portion of the sciatic nerve beyond the ligature absorbs the tetanus toxin.

The influence of high temperature on the course of experimental tetanus and streptococcic infection, O. Ritzmann (*Arch. Hyg.*, *61* (*1907*), *No. 4, pp. 355–384*).—In experiments with various laboratory animals it was found that mice maintained at a temperature of 35° C. became infected with tetanus much more readily than when kept at ordinary living temperatures. The effect of temperature upon tetanus infection with guinea pigs, however, was less striking.

The influence of cold upon experimental tetanus, Ciuca (*Compt. Rend. Soc. Biol.* [*Paris*], *62* (*1907*), *No. 16, pp. 858, 859*).—Experiments with small laboratory animals have already shown that cases of tetanus progress more rapidly and assume a more virulent form when the animals are subjected to excessively high temperatures. The author also found that similar effects were produced by subjecting the animal to low temperatures. The resistant power of the animal appears to be thereby reduced.

The action of sunlight upon bacteria with special reference to Bacillus tuberculosis, J. Weinzirl (*Jour. Infect. Diseases, 1907, May, Sup. 3, pp. 128–153, pls. 2*).—The author made a study of the various methods which have been used in determining the effect of sunlight upon bacteria. Objections are found to most of these methods in that they do not constitute true exposures, the bacteria being covered with glass or other material which absorbs and reflects some of the sun's rays. When bacteria were directly exposed to the rays of the sun without any covering over them, the author found that the germicidal action of sunlight was much more effective than it had previously been considered.

The organisms upon which observations were made were the bacilli of tuberculosis, typhoid fever, cholera, diphtheria, etc., but particular attention was given to the tubercle bacillus. It was found that this organism as well as other pathogenic nonspore-bearing bacteria is destroyed in from 2 to 10 minutes by direct exposure to sunlight. According to the author, the hygienic importance of sunlight has been considerably underestimated and nonspore-bearing bacteria, when freely exposed, are killed in from one-fifth to one-twentieth of the time previously considered necessary.

Cultural properties of tubercle bacilli, J. von Szabóky (*Centbl. Bakt.* [*etc.*], *1. Abt., Orig.*, *43* (*1907*), *No. 7, pp. 651–660*).—Detailed notes are given on the growth and behavior of tubercle bacilli on various culture media including lung agar, sputum agar, eggs, and tuberculous lung agar.

Protective vaccination of cattle against tuberculosis, F. Hutyra (*Ztschr. Tuberkulose*, *11* (*1907*), *No. 2, pp. 97–122*).—In the earlier experiments made by the author in testing von Behring's method of vaccinating cattle, results were obtained which led to a quite optimistic expression of belief in the permanent value of this method. Later experiments have caused the author to speak of the method with greater reserve. It appears that the resistance conferred by von Behring's method against subsequent intravenous injection with tubercle bacilli declines quite rapidly and disappears entirely toward the end of the first year. The resistance of inoculated cattle toward natural infection from other tuberculous cattle is never striking and disappears after a few months.

In further experiments to test von Behring's method 2 intravenous vaccinations were given in the place of the one previously recommended. It was found that the resisting power of cattle thus treated was at first very pronounced or almost absolute, but that it was not of long duration, disappearing entirely within 18 months. The author concludes from his experiments that at present the only method for controlling tuberculosis which has stood practical test is that of Bang.

An unusual form of tuberculosis in hogs, J. Böhm (*Ztschr. Fleisch u. Milchhyg., 17 (1907), No. 9, p. 311*).—In the examination of a case of advanced tuberculosis in a hog it was found that tubercles were present not only in the organs usually affected, but also in the fat tissue. The tubercles in the fat tissue showed no anatomical connection with muscle fibers or with lymph or blood vessels.

Tuberculosis in the region of certain canals near Modena, R. P. Rossi (*Clin. Vet. [Milan], 30 (1907), No. 1, pp. 2-7*).—A study was made of tuberculous cats and rats in the region of certain canals which were contaminated to some extent with tubercle bacilli. The author comes to the conclusion that fluid contaminations which enter the canal may have contributed to the increased percentage of tuberculosis among these animals, but that the refuse meat material transported in the canals is the chief source of the disease.

Distribution of tuberculin and mallein by the Bureau of Animal Industry, M. Dorset (*U. S. Dept. Agr. Yearbook 1906, pp. 347-354*).—Attention is called to the great importance of means for the diagnosis of infectious diseases in advance of the development of clinical symptoms. A brief historical statement is given of the use of tuberculin and mallein in detecting tuberculosis and glanders. The Bureau of Animal Industry furnishes tuberculin and mallein to Federal, State, county, or city officials under an agreement that the latter furnish records of the tests and of autopsies upon all animals which are slaughtered. During the fiscal year 1905-6 103,000 doses of tuberculin and 10,000 doses of mallein were distributed.

Observations on the mallein test, W. Jowett (*Vet. Rec., 19 (1907), No. 983, pp. 725-729*).—Considerable difference of opinion has prevailed regarding the length of time which should be allowed to elapse after one mallein injection before another one is given in cases of doubtful reaction. This matter has been carefully studied by the author, with the result that the interval between 2 mallein injections apparently need not be longer than a few days or merely long enough to allow the animal to return to a normal temperature. In a study of mallein reactions the thermic reaction appears to be more delicate and reliable than the local reaction at the point of injection.

Experimental glanders in guinea pigs, M. Nicolle (*Ann. Inst. Pasteur, 21 (1907), No. 4, pp. 281-294*).—A series of inoculation experiments was carried on in testing the reaction of guinea pigs to glanders virus obtained from different sources and subjected to different conditions of environment. When intracardiac injections of glanders virus were made, the external symptoms of the disease appeared after about 3 days in the form of pustular eruptions. An attenuated virus introduced directly into the heart appears to be the most effective way of producing immunity against glanders in experimental animals.

The author found that in a small percentage of cases subcutaneous inoculation of a mixture of normal serum and active virus produced a resistance in the experimental animal.

The conditions for formation of the capsule of the anthrax bacillus, T. STIENNON (*Compt. Rend. Soc. Biol.* [*Paris*], *62* (*1907*), *No. 15, pp. 821-823*).—The capsule appears most regularly and in a most pronounced manner on anthrax bacteria in infected animals. Bacilli with capsules are not surrounded with phagocytes and cause death more rapidly than nonencapsuled bacilli. The virulence of the bacilli with capsules was always greatest.

Decisions of the imperial health officials regarding the appearance of anthrax in cattle in the Schmeie region, GÄRTNER and C. DAMMANN (*Arb. K. Gsndhtsamt.*, *25* (*1907*), *No. 2, pp. 416-456*).—For some time anthrax has occurred among cattle along the regions of the river Schmeie, and upon investigation by the imperial health office it was found that in one part of the valley 103 cases had occurred during the past 12 years among 1,600 cattle, while in another section 138 cases had occurred among 46,000 cattle. The extent of infestation varied greatly in different parts of the valley, according to the favorable or unfavorable conditions for the distribution of the anthrax bacillus.

In the region in question there are a number of tanneries, and these institutions are directly connected with the spread of anthrax. The organisms gain entrance to the flowing streams through the waste water and subsequently infect cattle lower down the stream. In the opinion of the authors, it is impossible to control this trouble by the rejection of infected hides at the point of entrance into the Empire or by ordinary methods of furnishing a water supply for stock in the infected area. These methods may lessen the extent of anthrax to some extent, but can not prevent the appearance of the disease. The only effective means of controlling this trouble is found in the disinfection of all waste water from tanneries.

Mammitis in cows, H. CARRÉ (*Rev. Gén. Méd. Vét.*, *9* (*1907*), *No. 106, pp. 561-564*).—In cases of contagious mammitis observed by the author an organism was isolated which is described as new under the name *Bacillus mastitidis contagiosæ*. This organism appears not to be a rare one and is believed by the author to be of considerable importance in the etiology of mammitis.

The station for the control of rinderpest at Chita, M. P. SLYESAREVSKI (*Arch. Vet. Nauk* [*St. Petersb.*], *36* (*1907*), *No. 2, pp. 104-132*).—This station has been in operation since 1901, receiving both government and private funds. Its main purpose is the study of rinderpest and in the different laboratories connected with the institution and in the cattle corrals and stables experiments are being carried on to determine the means by which the disease is transmitted and the value of the various methods of immunization which have been proposed for controlling it.

Poisoning of cattle from Taxus baccata, GRIMME (*Deut. Tierärztl. Wchnschr.*, *15* (*1907*), *No. 23, pp. 321, 322*).—In several cases poisonous symptoms were produced in cattle as a result of eating *Taxus baccata*. A post-mortem examination was made of one animal during which it was found that the liver and spleen were considerably swollen and that the exterior of the rumen was grayish red. Reddened spots were also observed in the small intestines.

On the chromatin masses of Piroplasma bigeminum, the parasite of Texas cattle fever, H. B. FANTHAM (*Quart. Jour. Micros. Sci.* [*London*], *n. ser.*, *51* (*1907*), *No. 202, pp. 297-324, pl. 1, figs. 44*).—In all specimens of *Piroplasma bigeminum* stained and examined by the author there was one or more chromatin masses. In the ovoid and pyriform parasites there is usually a large chromatin mass and also a smaller, denser one as well as a mesh-like structure of chromatin. A number of variations occur in the relative positions and relative sizes of these different chromatin bodies.

On the cultivation of a bovine piroplasma, M. MIYAJIMA (*Philippine Jour. Sci.*, *2* (*1907*), *No. 2, pp. 83-91, pls. 2*).—For some time the author has noticed the presence of a protozoan organism closely resembling *Piroplasma parvum* in Japanese cattle. Further study of this organism indicated that it belongs to the species *P. parvum* and is found in Japanese and Korean cattle. The organism may be readily cultivated outside of the animal body by the use of suitable nutrient media. The parasites undergo a developmental change in blood bouillon, finally taking the form of a typical trypanosome which is not to be detected in the blood of infected animals. According to the author a simple mixture of blood and bouillon is the most suitable mixture for the cultivation of *P. parvum* and *Trypanosoma lewisi.*

Studies on the morphology and life history of Piroplasma canis, G. H. F. NUTTALL and G. S. GRAHAM-SMITH (*Jour. Hyg.* [*Cambridge*], 7 (*1907*), *No. 2, pp. 232–272, pls. 3, figs. 14*).—The biology and life history of the blood parasite of canine piroplasmosis was carefully observed for 550 hours in order to determine as nearly as possible the different stages under which this parasite appears. The observations made by the authors indicate the occurrence of morphological changes in this parasite somewhat different from those hitherto described.

It appears that a free pyriform parasite, after entering a red blood corpuscle, ordinarily assumes a round form, then enlarges, becomes amœboid, and again rounded. After a short resting period two symmetrical processes are protruded, become pear-shaped, absorb the protoplasm of the mother cell, and finally separate into two free parasites.

A new preparation for the treatment of acute and chronic swine plague, BUROW (*Berlin. Tierärztl. Wchnschr., 1907, No. 23, pp, 450–452*).—Laboratory experiments have been carried on for the past year and a half in an endeavor to produce a bacterial preparation which will be effective in the treatment of swine plague. The product, which is prepared under the author's direction, has been obtained and has been tested on about 700 hogs with quite satisfactory results. The coughing and other external symptoms of swine plague disappear within 3 or 4 days. The preparation is claimed to be absolutely harmless and is administered hypodermically in doses of 5 cc.

Exostoses on the metacarpus of the horse, V. OELKERS (*Monatsh. Prakt. Tierheilk., 18* (*1907*), *No. 8–9, pp. 337–384, pls. 6, figs. 5*).—The literature relating to splints is critically reviewed in connection with bibliographic references. The present article is a report on one of the most extensive investigations thus far made of the anatomy and etiology of splints in horses. An examination was made of 652 army horses, with the result that 68 per cent was found to be affected. The splints observed in the 448 cases could readily be classified into intermetacarpal, postmetacarpal, and traumatic splints. The anatomical features of each of these different groups of splints are presented in detail.

As a result of these investigations, the author comes to the conclusion that the exostoses commonly known as splints are caused primarily by the friction of the interosseous ligament at its fixed points upon the underlying bones. This friction causes a gradual ossification in the ligament, which, by extension upward and downward, may cause an unusual strain upon the tendons and ligaments which are attached to the posterior angle of the normal splint bones leading to a periostitis the result of which is the pathological splint known to veterinarians.

In the treatment of splints the author recommends rest for all cases and external applications which are likely to induce a resorption of the bony process. If the case seems to warrant surgical interference, the bone growth may be removed by an operation.

Staggers or forage poisoning in horses, S. S. CAMERON (*Jour. Dept. Agr. Victoria, 5* (*1907*), *No. 4, pp. 242–246*).—Rather extensive fatalities have occurred among horses in various parts of Victoria, apparently as a result of eating injurious forage. In one outbreak the trouble was due to feeding oat hay which had been allowed to become moldy in the butts of the sheaves. The exact cause of the disease has not been determined, and further study is necessary to elucidate its etiology.

Diseases of fowls, G. BRADSHAW (*Agr. Gaz. N. S. Wales, 18 (1907), Nos. 1, pp. 26–39; 3, pp. 207–213, figs. 2*).—An account is given of the symptoms, post-mortem appearances, and method of treatment in cases of roup and fowl cholera.

Roup, L. E. W. BEVAN (*Rhodesian Agr. Jour., 4 (1907), No. 4, pp. 392–397*).—The symptoms and occurrence of this disease are briefly discussed. In preventing roup it is recommended that strict quarantine measures be observed, that careful supervision be exercised in the selection of food and water supply for fowls, and that affected birds be placed in small rooms or boxes and fumigated with formaldehyde.

Sleepy disease in fowls, C. DAMMANN and O. MANEGOLD (*Arch. Wiss. u. Prakt. Tierheilk., 33 (1907), No. 1–2, pp. 41–70, pl. 1*).—An affection of fowls known under the name of sleepy disease has appeared here and there since 1904. According to the authors this disease is due to *Streptococcus capsulatus gallinarum*. The organism is described and notes are given on its behavior on different culture media and upon its resisting power. It is destroyed by subjection to a temperature of 100° C. for one-half minute or 50° C. for 20 minutes. The organism is quite susceptible to the action of disinfectants such as carbolic acid, cresol, etc.

The streptococcus in question shows a high pathogenic power for fowls and is present both in the blood and affected organs. The incubation period varies from 6 to 14 days and the course of the disease from 1 to 3 weeks. One of the most striking symptoms is the persistent sleepiness. The feathers are ruffled and catarrh is apparent upon the mucous membranes and conjunctiva.

An arthritis in geese and ducks caused by Staphylococcus pyogenes aureus, FREESE (*Deut. Tierärztl. Wchnschr., 15 (1907), No. 23. pp. 322–324*).—Affected birds become more or less emaciated and show symptoms of lameness or even inability to walk. In the joints in which the chief lesions occur a serous or sero-fibrinous inflammation is observed together with a hemorrhagic condition of the bone marrow. In chronic cases of the disease a purulent ostitis is observed. In inoculation experiments negative results were obtained with common fowls, pigeons, and rabbits. No direct treatment for the disease has been devised and reliance must, therefore, be placed upon prophylactic and disinfectant measures.

RURAL ENGINEERING.

Irrigation in the Yakima Valley, Washington, S. O. JAYNE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 188, pp. 89, pls. 2, figs. 4*).—This bulletin describes the Yakima Valley by sections, giving the areas, crops, physical features, climate, water supply, water rights, and systems of distribution. The chief canals are described as to their dimensions, the area covered, the area irrigated, and the system of management.

The practice of treating the interior of flumes with asphaltum or tar, or a mixture of the two, has been adopted to some extent as a means of preserving the material and preventing leakage. It is stated that for new structures and dry lumber the use of either material may be recommended.

The cost of preparing and seeding new lands, as given for a number of sections of the valley, varies from $10 to $50 an acre, depending upon the amount of vegetation to be removed and the condition of the surface of the land. The cost of water rights in different canals in the valley varies between $25 and $75 per acre, while the annual assessments to cover maintenance vary from $1 to $2 per acre.

Duty of water measurements are given for a large number of canals, covering in some instances several years. Measurements for the Sunnyside Canal cover 7 years and show a constant decrease in the quantity of water used from 1898, when the average depth used was 11.4 ft., to 1906, when the average depth used was 6.5 ft. General statements for 18 of the larger canals show variations in depths used of from 3 to 12½ ft.

The use of these large quantities of water, together with the leakage from ditches, has injured much land and made drainage necessary in several sections. Seepage measurements on one canal showed losses of from 1 to 3 per cent of the volume carried per mile of ditch.

The report closes with a statement regarding the work of the Reclamation Service in the Yakima Valley.

Seepage and drainage, I, E. T. TANNATT and A. P. ANDERSON (*Montana Sta. Bul. 65, pp. 63, pls. 4*).—This bulletin calls attention to the evils of over-irrigation and leaky irrigation ditches and describes the drains installed upon a part of the Montana Station farm at Bozeman. The field drained had a thin top soil of muck and loam underlaid by gravel of undetermined depth. The drains were first used, but it was found that the joints became cemented, probably by silt carried in the irrigation water, rendering the drains useless. Box drains without bottoms were substituted and proved successful, while in addition they were cheaper than the tile drains. Detail drawings of the box drains and a bill of materials are given.

Reclamation of tide lands, J. O. WRIGHT (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1906, pp. 373–397, pls. 5, figs. 6*).—This paper is a general statement regarding the extent of tide lands, their value when reclaimed, and methods of reclamation. The soil of these marshes is composed of sediment mingled with the remains of animal and vegetable life. Chemical analyses of numerous samples and yields of crops grown on reclaimed tracts show that they are very productive and that, with proper treatment, including the leaching out of excess salt, they are extremely valuable.

The general method of reclamation is diking to keep out tide water and internal drainage. Where the variation between high and low tide is sufficient drainage can be accomplished by the use of automatic tide gates which allow the drainage water to escape at low tide. Where this difference is small it is necessary to pump the drainage water over the dikes. The dikes may be constructed by hand, with teams and scrapers, or with dredges, depending upon the size necessary. The reclamation of these marshes has been successful where dikes have been properly constructed and protected, and failures can in most cases be attributed to neglect of the proper precautions. The essentials of a dike are a wide berm between the water and the foot of the dike, flat slopes properly protected, and proper preparation of the foundation to insure a good joint between the natural earth and the embankment. Slopes on the water side should not be less than 3 to 1 and on the land side not less than 2 to 1. All vegetable matter should be removed from the foundation and intercepting ditches should be excavated and refilled just inside of each toe of the dike.

Dredges of different kinds are described and drawings and bills of material for both concrete and timber tide gates are given.

Object-lesson roads, L. W. PAGE (*U. S. Dept. Agr. Yearbook 1906, pp. 137–150, pls. 4*).—In this article Director Page outlines the work of the Office of Public Roads of this Department, showing that its work is divided into two general classes—the economic questions of road management and the practical features of road construction and maintenance.

The object-lesson road is the method chosen for making available the results of investigations of the office in road construction. "Briefly stated, the purposes of object-lesson roads are, first, to introduce among local road builders correct methods of construction and maintenance; second, to demonstrate the advantages of a properly built road in order to stimulate public sentiment for road improvement and arouse a spirit of progress; third, to afford a basis for estimating cost of additional road construction, which may be subsequently carried on by the county or community; fourth, to demonstrate the availability and relative value of local materials as far as practicable."

Tables are given showing the location of object-lesson roads constructed in 1904–5 and 1905–6, showing the kind and source of material, the distance transported, the dimensions of the road, the cost per square yard and per mile, and the cost of labor per day. Reports regarding the present condition of a number of the roads built are included in the paper.

A rotating traction plow, C. Lumia (*Coltivatore, 53 (1907), No. 17, pp. 529–532, fig. 1*).—The author describes a very unusual type of plow in which the ordinary plowshare is replaced by a pair of auger-like screws which precede the machine and are rotated in opposite directions with respect to each other as the machine moves forward. The machine is operated by a gasoline motor and is self-propelling. It is claimed to possess certain advantages in giving the soil a more thorough stirring than is possible with the ordinary plow. Turning and operating the plow leaves $\frac{1}{11}$ of the area of the field upon which it is used unplowed, and in a 10-hour day it is claimed that 2.5 acres may be plowed to a depth of 8 in. in compact soil at a total expense of $7.60, with gasoline at a price equivalent to 40 cts. per gallon.

Corn harvesting machines, M. Ringelmann (*Jour. Agr. Prat., n. ser., 14 (1907), No. 32, pp. 172–175, figs. 6*).—Various simple American devices for this purpose are described.

On the peculiarities of denatured alcohol (*Masch. Ztg., 5 (1907), No. 7, p. 80*).—Apparatus using denatured alcohol such as motors and incandescent lamps, is often injured and its working parts corroded by the products liberated in the process of combustion. The question has arisen as to which of the materials in consideration, the alcohol itself with its impurities such as aldehyde and ether, or the denaturing materials like methyl alcohol, benzine, etc., is the agent responsible for the corrosive effect. The denaturants have formerly been held in suspicion, but recent investigations by Lindet, Heinzelman, and others have shown that the usual impurities of undenatured alcohol, viz, aldehyde and ethyl acetate, may cause corrosion to a greater or less degree, though the time required to effect noticeable injury is longer than with the denatured alcohol. The effects of using the latter are briefly summarized as the formation of acetic acid, the clogging of the inlet and outlet valves, corrosion of the motor cylinder, clogging and corrosion of burners, hardening of wicks, and early destruction of the wire parts of incandescent burners.

The means recommended to obviate this trouble is the removal of the aldehyde and acetates to the greatest possible extent and the use of benzine of a not too high boiling point.

RURAL ECONOMICS.

Freight costs and market values, F. Andrews (*U. S. Dept. Agr. Yearbook 1906, pp. 371–386*).—The author discusses the cost of hauling from farms and the prevailing freight rates on cotton and wheat in 1906 to the principal shipping and exporting points in the United States, the ocean freight rates to the

United Kingdom, and the effect of the various charges on the price of these staple farm products.

The estimated average cost of carrying cotton and wheat in the United States and to the United Kingdom during the year ended June 30, 1906, is as follows: From local shipping points to seaports, 40 cts. per 100 lbs. for cotton and 12.6 cts. per bushel for wheat; from all ports to Liverpool, 32 cts. per 100 lbs. for cotton and 9.6 cts. per bushel for wheat. At Galveston, New Orleans, Savannah, and New York, which are the 4 principal export points for cotton, the mean of the daily closing prices for Upland middling cotton was 11 cts. per pound, while in England the mean price was 12.1 cts. per pound. The average price of wheat in Chicago, Minneapolis, and Kansas City was 85.1 cts. per bushel, while the average import value of all wheat brought into the United Kingdom from the United States was 95.9 cts. per bushel. The average freight rate on wheat to the United Kingdom from all exporting countries was 9 cts. per bushel for distances ranging from 3,000 to 15,000 miles, which rate was "only one and two-thirds times the cost of hauling over 9 miles of country roads in the United States."

"Judging from the changes during the past few generations, it is natural to expect that costs of freight on land and water may be lower in the future than at present. Improved methods of loading and unloading freight, economies in the disposition of cars and vessels so as to avoid more than at present the hauling of empty cars and the making of voyages in ballast, and an increase in the quantity of valuable freight paying high rates per unit of weight would all tend to lower the cost of transporting farm products."

The effect of wages and the cost of products in different systems of cultivation, WATERSTRADT (*Fühling's Landw. Ztg., 56 (1907), No. 10, pp. 329–341*).—The author gives the methods and results of investigations to determine what system of crop rotation will give the best financial returns when the factors entering into the cost of production are known. Six systems of rotation were tested, and the data regarding the number of hours of labor, cost of fertilizers, value of crops, etc., are tabulated and discussed. In general it is believed that there really is no best system of rotation, as managing ability, the cost of production, and the wages of labor are more important in determining final returns than any system of cultivation.

The agricultural and rural institutions of the world at the commencement of the twentieth century, L. GRANDEAU (*L'Agriculture et les Institutions Agricoles du Monde au Commencement du XX*^{e} *Siècle. Paris: Govt., 1905–6, vols. 1, pp. VII+754, figs. 193; 2, pp. 751, figs. 126; 3, pp. 752, figs. 130; 4, pp. 674, figs. 107*).—This is a general treatise on the agriculture of the world based on the agricultural and horticultural exhibits at the Paris Exposition in 1900. The statistics of each country are separately discussed and embrace every phase of agriculture, forestry, and rural economics. The data having been compiled from reliable sources, serve as useful comparisons of the population, agricultural production, and rural economy of nearly all nations of the world at the opening of the twentieth century.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 9 (1907), No. 9, pp. 65–72*).—Statistics and notes on the condition of crops, and the supplies, value, prices, and imports of farm and forest products in the United States and foreign countries are summarized.

[**Agricultural statistics of Belgium**] (*Ann. Statis. Belg., 37 (1906), pp. XLI–XLVIII, 285–313*).—Statistical data on the agricultural population, wages of laborers, extent of arable land and forests, quantity and prices of products, number of live stock, etc., are tabulated and discussed. The data in general are given for the years 1880 to 1895, but in some instances are brought down to 1905.

Agricultural credit [in Brazil], J. I. Tosta (*Bol. Dir. Agr. Bahia, 9 (1907), No. 3, pp. 227-232*).—This article gives sections of the laws passed in 1907 authorizing the establishment of cooperative societies in Brazil and a government loan of a million dollars to promote credit among the peasantry on the basis of personal security. In discussing these laws the author points out that "the government loans money to an agricultural bank at 4 per cent interest, the bank lends to cooperative societies at 5 or 6 per cent, . . . and the society loans to members at 8 per cent," and by this means the poor peasant is able to borrow money with no security at the same rate of interest which landowners have to pay in Brazil on the basis of real estate.

Report on the agricultural bank in the Philippines, E. W. Kemmerer (*Rpt. Philippine Com., 1906, pt. 1 pp. 485-641*).—This report discusses the agricultural conditions of the Philippine Islands, the high rates of interest (10 to 120 per cent) charged by money lenders in different provinces, the various forms of agricultural credit adopted in many countries, and suggests plans believed to be best suited to present Philippine conditions. The law passed by Congress since the submission of the report is included, together with appendixes on agricultural credit in the Philippines, the agricultural bank of Egypt, the provisions of the code of commerce concerning mortgage and agricultural banks, the statutes of the East Prussian and West Prussian Landschafts, the French law regarding societies for the grant of land credit, the articles of the "Credit Foncier of France," the laws and regulations relating to the Hungarian Boden-Kredit Institut, extracts from the laws and regulations regarding real credit in Italy, the law relating to the mortgage bank of the Canton of Berne, Switzerland, abstracts of the agricultural banking laws of Australia and New Zealand, etc.

[Agriculture and cooperation in Denmark], J. L. Benton (*Daily Consular and Trade Rpts. [U. S.], 1907, No. 2916, pp. 1, 2*).—Statistics show Denmark's population in 1906 to have been 2,600,000, of which 54 per cent belonged to the agricultural classes. Only one-fifteenth of the agricultural population are tenants or renters, the remainder being freeholders. The laws prevent the creation of large farms, and the following table shows the classification of farms in 1906:

Classification and total acreage of lands in Denmark, 1906.

Acres	Number	Total acreage.	Acres.	Number.	Total acreage.
7 or less	116,614	239,604	135 to 270	6,502	1,169,484
7 to 11	16,988	159,832	270 to 540	1,590	574,946
11 to 22	28,992	473,598	540 and over	822	964,327
22 to 33	17,723	496,962			
33 to 67	35,257	1,752,121	Total	250,103	8,177,169
67 to 135	25,615	2,246,295			

Out of the total acreage in farms, 5,267,900 acres belong to farms ranging in size from 33 to 270 acres in extent. In addition to the above there are some 68,000 small holdings containing about 4 acres each.

Statistics for 1906 show that there were 1,085 cooperative dairies with 158,170 members, 33 bacon factories with 91,000 members, and a cooperative egg exporting society with 500 local centers. Statistics of the business transacted by these organizations in 1906 are included.

General agricultural conditions in Calabria, D. Taruffi (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 4 (1907), No. 1, pp. 15-38*).—This article describes the geography, soils, river and road systems, population, climate, and agriculture of Calabria, and gives a survey of the economic conditions of the peasant classes.

As a whole Calabria is largely agricultural and had in 1901 a total of 1,370,208 inhabitants. Statistics are given which show, however, an increasing rate of emigration, 62,290 laborers having emigrated in 1905. From census figures the author calculates that for every 100,000 inhabitants 4,443 emigrants from Calabria in 1905 as compared with 2,161 for the whole of Italy. The conditions surrounding the home life of the peasantry are said to be exceedingly wretched, resulting in a high death rate, a steady stream of emigration, and great depression in agriculture.

AGRICULTURAL EDUCATION.

Progress in agricultural education, 1906, D. J. CROSBY *(U. S. Dept. Agr., Office Expt. Stas. Rpt. 1906, pp. 213–300, pls. 3, fig. 1)*.—This is an annual review of the leading features of progress in agricultural education in this country and abroad, including the general educational work of this Department and that of this Office, of the Association of American Agricultural Colleges and Experiment Stations, and of the different agricultural colleges, secondary schools, and primary schools throughout the country.

Considerable attention is given to the second session of the Graduate School of Agriculture at the University of Illinois, and to the development of secondary schools of agriculture in Maryland and Georgia. A course in agriculture for the Georgia schools is given in detail, as is also a suggestive course for the elementary public schools of California.

Statistics of land-grant colleges and agricultural experiment stations, 1906, MARIE T. SPETHMANN *(U. S. Dept. Agr., Office Expt. Stas. Rpt. 1906, pp. 177–212)*.—A compilation from official sources of general statistics, attendance, value of funds and equipment, and revenues of the land-grant colleges, and of the lines of work, revenues, and additions to equipment of the agricultural experiment stations in the United States.

District agricultural schools of Georgia *(Bul. Univ. Ga., 7 (1907), No. 11, Sup., pp. 47)*.—This bulletin contains a copy of the act providing for the establishment and maintenance of schools of agriculture and the mechanics arts in the respective Congressional districts of Georgia, a list of the trustees, the location of the schools, their faculties, resolutions of the board of trustees, a report of the committee on curriculum, a detailed description of the curriculum, lists of books on agriculture, and a schedule of hours.

The minimum age for entrance into these schools is 14 years for boys and 13 years for girls. The course of study extends through 4 years, including at least one year of common school or elementary studies. At least 3 hours a day of class-room work must be devoted to agriculture and related sciences.

The principals of the schools are to provide from time to time for such lectures on agriculture and the related subjects as the funds of the school will permit, and also for short courses for adult farmers in so far as the same may not conflict with the other work of the schools.

Students may be allowed fair compensation for work done on the farm or in the shop. One-fourth of the students, or such number as the principal may determine as necessary to continue the operation of the farm and shop, are to be required to remain on the farm during vacation. For work required during this time the students will be given fair compensation.

The State farmers' institute director is to arrange farmers' institutes at these schools and secure the help of their faculties in conducting institutes at other places.

Several of the schools are planning to open in January, 1907.

The farmers' institutes in the United States, 1906, J. HAMILTON (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1906, pp. 301–357*).—This is the annual report of the Farmers' Institute Specialist of this Office for 1906. It includes a discussion of the progress and problems of the institute movement, an account of the annual meeting of the American Association of Farmers' Institute Workers, a discussion of the agricultural education extension movement, and detailed reports and statistics on farmers' institutes in the different States and Territories.

Market-day lectures, 1905–6 (*Chelmsford: County Tech. Labs., pp. 136*).—These are reports of addresses to farmers delivered at Chelmsford and Colchester during the winter months. They relate to various phases of animal husbandry, dairying, crop production, poultry keeping, the uses of manure, and farm management.

Introduction of elementary agriculture into schools, A. C. TRUE (*U. S. Dept. Agr. Yearbook, 1906, pp. 151–164*).—An account is given of the growth of interest in the teaching of elementary agriculture in public schools as indicated by the attitude of men of prominence, farmers' organizations, school officers and teachers, and by recent State legislation. Progress in the formulation of courses in elementary agriculture, the preparation of text-books and manuals, the development of training courses for teachers, the organization of agricultural schools, and the number of pupils studying agriculture is reviewed and some suggestions are made concerning ways in which farmers may help the schools.

The training of the teachers of domestic science, MARY E. MARSDEN (*Rpt. Brit. Assoc. Adv. Sci., 1906, pp. 784–786*).—In this paper the author states that students who have had a good secondary education are those best fitted for special training in domestic science, but that the ideal preparation for a domestic science course is a science degree followed by a special training in domestic science. The following subjects are briefly discussed: Time and scope of training, suggested scheme of training, including arts and science, instruction and practice in method of teaching, including (1) the elements of psychology, the study of class management, and school organization, (2) blackboard drawing and elocution, and (3) actual practice in class teaching, and additional aids to the training of domestic science teachers, such as a reading room and reference library, literary and debating societies, and reading clubs.

The duty of education authorities to the nation respecting the teaching of domestic subjects, MARGARET E. PILLOW (*Rpt. Brit. Assoc. Adv. Sci., 1906, p. 786*).—An abstract of a paper read at the annual meeting of the British Association for the Advancement of Science in August, 1906, at York.

School training for home duties of women, A. SMITHELLS (*Rpt. Brit. Assoc. Adv. Sci., 1906, pp. 781–784*).—This paper is a plea for the development of a science of the household free alike from the pedantry of formal science and from the unprofitable memorizing of dietetic statistics. The author has found it possible to arrange a "course of science lessons in which scientific discipline and scientific method can be inculcated by simple experimental work, based entirely on matters of the household and of daily life; where the information acquired is truly useful knowledge, and where the minds of the pupils are awakened to the fact that the household is a laboratory of applied science that may constantly engage the intelligence."

The problem of girls' education in elementary schools, with special reference to training for home life, MILLICENT MACKENZIE (*Rpt. Brit. Assoc. Adv. Sci., 1906, p. 787*).—An abstract of a paper read at the annual meeting of the British Association for the Advancement of Science in August, 1906, at York.

School gardening, D. R. WOOD (*Jour. Ed.* [*Boston*], *65* (*1907*), *Nos. 16, pp. 428, 429; 17, pp. 457, 458*).—The first part of this article contains practical suggestions for locating the school garden and draining and enriching the soil, hints on arrangement, testing seeds, planting, watering, and what to plant in the way of vegetables, flowers, and trees. The second part gives a suggestive outline for work in the 8 grades, and lists of suitable vegetables, flowers, and plants for the school garden.

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1906 (*U. S. Dept. Agr. Yearbook 1906, pp. 720, pls. 43, figs. 22*).—The Yearbook for 1906 contains a report of the Secretary on the work of the Department during the year, 25 special papers abstracted elsewhere in this issue, and an appendix consisting of an agricultural directory, a review of the progress in different lines of agriculture, and agricultural statistics.

Annual Report of the Office of Experiment Stations, 1906 (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1906, pp. 434, pls. XVI, figs. 13*).—This includes the usual report on the work and expenditures of the Office of Experiment Stations and the agricultural experiment stations in the United States, including Alaska, Hawaii, and Porto Rico; statistics of the agricultural colleges and experiment stations for 1906; a brief account of the nineteenth annual meeting of the Association of American Agricultural Colleges and Experiment Stations; and several articles and reviews abstracted elsewhere in this issue.

Thirtieth Annual Report of Connecticut State Station, 1906 (*Connecticut State Sta. Rpt. 1906, pt. 6, pp. XV*).—These pages include the organization list of the station, an announcement concerning the work of the station, a report of the board of control, and a financial statement for the fiscal year ended September 30, 1906.

Nineteenth Annual Report of Massachusetts Station, 1906 (*Massachusetts Sta. Rpt. 1906, pp. 218*).—This includes the organization list of the station, a report of the director, a financial statement for the fiscal year ended June 30, 1906, a report of the meteorologist, and other departmental reports abstracted elsewhere in this issue.

Nineteenth Annual Report of Vermont Station, 1906 (*Vermont Sta. Rpt. 1906, pp. 207–388*).—This includes the organization list of the station, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1906, a report of the director, abstracts of Bulletins 117–123 of the station issued during the year, the results of miscellaneous analyses, and numerous articles abstracted elsewhere in this issue.

Abstract of Nineteenth Annual Report, 1906 (*Vermont Sta. Bul. 129, pp. 91–152, pl. 1*).—This is a résumé of the annual report of the station noted above.

Sixteenth Annual Report of Wyoming Station, 1906 (*Wyoming Sta. Rpt. 1906, pp. 96*).—This includes the organization list, a report of the director on the work and publications of the station during the year, a financial statement for the fiscal year ended June 30, 1906, reports of the animal husbandman, the chemist, and the meteorologist abstracted elsewhere in this issue, and of the agriculturist and horticulturist, the botanist and the irrigation engineer, and plans of station work for the ensuing year. An appendix contains a classification of agricultural literature designed primarily for the use of animal husbandmen.

NOTES.

California University.—Leroy Anderson, at present in charge of the California Polytechnic School, has been appointed instructor in agriculture at the university and director of the farm schools at Fresno and Davis. A 3-day farmers' institute was held at Davis October 29 to 31 as a means of bringing the new institution into close touch with the public, at which President Wheeler and Director Wickson of the station were among the speakers.

Connecticut College.—Twelve-week courses in creamery practice, dairying, and pomology, a 6-week poultry course, and a 10-day course are announced in connection with the winter school to begin January 7, 1908.

Delaware College.—Director Hayward of the station has been appointed dean of the department of agriculture in the college.

Florida University.—According to a note in *Science*, H. S. Davis, Ph. D. (Harvard, 1907), has accepted an appointment as professor of biology.

Georgia Station.—H. N. Starnes, biologist and horticulturist, has resigned, to take effect January 1, 1908.

Illinois Station.—Andrew Ystgard, assistant in chemistry in the department of agronomy since 1904, died October 26, after a protracted sickness with typhoid fever. He was 34 years of age, a graduate of the Agricultural College of Norway and of the Trondhjem College of Engineering, and was for a time a student at the Wisconsin College of Agriculture.

Indiana University and Station.—A corn and stock judging school is to be held at Rushville from December 16 to 21, in charge of G. I. Christie and W. A. Cochel. Instruction will be given daily in the scoring of corn and stock, in addition to lectures. A course in domestic science has also been arranged. It is expected to reach a large number of farmers in this way who can not leave home to attend the short courses at the university.

H. A. Hopper, assistant in dairy husbandry in the Illinois University and Station, has been given charge of dairy field work and has entered upon his duties.

Kansas College and Station.—E. H. Webster, who was recently elected professor of dairying and dairyman, has decided to remain as chief of the Dairy Division of this Department.

Louisiana University and Stations.—F. H. Billings, professor of botany and bacteriology, has resigned to accept a corresponding position at the University of Kansas, and is succeeded by Reginald S. Cocks. Other appointments include A. F. Kidder, assistant in soil physics in the Illinois Station, as assistant professor of agronomy; S. W. Pipes, jr., as assistant in horticulture at the university; W. P. Naquin as assistant sugar chemist at the Audubon Park Station, and W. D. Morgan and R. Baus as assistant chemists at the Baton Rouge Station.

Maine Station.—In connection with the poultry investigations a laboratory has recently been built for use in the experimental work in breeding. The building has been designed with special reference to surgical work, and consists of a preparation room and general laboratory, a sterilizing room, and an operating room, arranged in series. For the better maintenance of aseptic conditions, the walls and ceilings are heavily coated with white enamel throughout, and all sharp angles and projections have been avoided in the construction.

Michigan College.—J. Fred Baker, professor of forestry in Colorado College, has been appointed professor of forestry to succeed E. E. Bogue, deceased.

Minnesota University and Station.—A. R. Kohler, instructor in horticulture at the Michigan College, has been appointed assistant horticulturist and has entered upon his duties.

Missouri University.—*Science* notes the appointment of Dr. P. F. Trowbridge as assistant professor of agricultural chemistry, and of N. D. Hendrickson, C. R. Moulton, and L. F. Shackel as assistants in the same department.

Nebraska Station.—Stella A. Hartzell has been appointed assistant in chemistry.

New Hampshire College and Station.—*Science* notes the appointment of W. M. Barrows as assistant in zoology.

New York State Station.—Recent changes in the station staff include the resignations of H. E. Hodgkiss, assistant entomologist, to accept a position with the State entomologist of Illinois, and of P. W. Flint, assistant chemist, to take up postgraduate work at the University of Illinois. A. R. Rose, assistant chemist, has been given a year's leave of absence for postgraduate work at Yale University.

North Dakota Station.—The bacteriological laboratory of the division of biology has been largely rearranged and more thoroughly equipped for the study of the indefinite flora of soil. The plant house of the botanical division has been fitted up with a complete temperature regulation system, by which the temperature of any room may be maintained quite constantly. The botanist is keeping in touch with farmers of the State by means of press bulletins giving recommendations arising from the work of the station as it progresses.

Experiments in the eradication of weeds in grain fields have been undertaken on a plan more extensive than heretofore. Field demonstrations have been conducted at 6 different points in the State on fields of from 50 to 100 acres each, special attention being given to a study of the machinery most suitable for applying solutions. Several new chemicals have been tested, but so far as iron sulphate and copper sulphate are concerned, no material deviation has been noted from the principles enunciated from the original investigations of the station.

Ohio University.—Ten-week winter courses, to begin January 6, 1908, are announced in the breeding and feeding of live stock, stock judging, soil fertility, farm crops, horticulture, farm mechanics, farm management, dairying, veterinary medicine, and poultry husbandry.

Rhode Island Station.—B. L. Hartwell, formerly associate chemist, has been made chemist. H. S. Hammond, assistant chemist, has resigned to accept a position at the Macdonald Agricultural College.

Vermont University and Station.—Morrill Hall, the new agricultural building now in course of construction, will be dedicated on December 11 at the time of the meeting in Burlington of the State grange.

Virginia Station.—Recent appointments include Lyman Carrier as agronomist, and F. D. Harmon as herdsman.

Washington College and Station.—H. B. Barry, a graduate of the college and last year a postgraduate student at the University of Illinois, has been appointed soil physicist in the station and will devote his entire time to studies of soil-moisture problems. R. S. Northrop, whose appointment as superintendent of the Puyallup substation was noted in a previous issue, has decided to remain with the Utah College and Station.

The station has adopted the plan of issuing a series of popular bulletins, giving concise summarized statements of the results of experiments for wide distribution among the farmers of the State. For this purpose the mailing list is being largely increased. Larger bulletins, giving full details of experimental data, will still be issued for distribution to other station workers and to interested parties who may request them.

A four years' investigation of methods of combating the codling moth has just been successfully completed, with the result that in 4 large orchards, located in different sections of this State, aggregating 80 acres of trees, an average of 99.6 per cent of fruit free from worms was obtained this year.

A wing of a new veterinary building to be used jointly by the college and station is in process of erection. The contracts have been let for a new farm barn to cost $7,000, on which work will begin at once. The new recitation building to cost $125,000, the library and assembly hall to cost $135,000, and the domestic science building to cost $25,000, provided for the college by the last legislature, are now in process of erection.

A series of traveling dairy schools is to be conducted by the extension bureau of the college, work being carried on for 10 days in each locality visited.

West Virginia University and Station.—At the recent meeting of the State Board of Trade at Elkins, Director J. H. Stewart presented a report for the committee on agriculture on the agricultural conditions and needs of the State. station is in process of erection. The contracts have been let for a new farm President D. B. Purinton and D. W. Working were also among the speakers. T. C. Johnson, assistant professor of horticulture and botany, has resigned to accept the management of the Virginia Truck Experiment Station at Norfolk. This station was established the past season for the purpose of studying the trucking industry. It is maintained from funds of the State Board of Agriculture, the local community providing the land and equipment.

Wisconsin University.—L. E. Reber, dean of the school of engineering of the Pennsylvania College, has been elected director of extension work. This will consist of lectures and correspondence for all courses of study in the university, for which university credits toward graduation will be allowed, subject to a regulation prescribing a 2-year minimum of resident study at the university.

Louise Johns has been appointed instructor in soils, and J. F. Reubensaal instructor in pasteurizing.

Association of Official Agricultural Chemists.—The twenty-fourth annual convention of this association was held at the Jamestown Exposition, Norfolk, Va., October 9–11, with about 100 delegates and visitors in attendance.

The presidential address by J. P. Street, of the Connecticut State Station, dealt especially with suggestions for the improvement of the efficiency of the work of the association. Attention was directed to some of the unsolved problems confronting the association, such as the question of the availability of potash in various forms and of basic slag, the provision of additional methods in the analysis of food and drugs, and the need for further differentiation of the constituents of the nitrogen-free extract of feeding stuffs. As a means of securing greater opportunity for the discussion of papers, a radical change in the meetings was suggested and later adopted. In the future one day of the convention is to be devoted entirely to the reading of papers and their discussion, the convention being divided for this purpose into three sections covering the same subjects as the present committees on recommendations. All papers to be read in these sectional meetings are to be referred in advance to the proper committee with full power to reject them or to assign places for them in the programme.

A second recommendation of the president suggested the appointment of a permanent committee on methods as a means of securing greater uniformity in the form of expression and arrangement from year to year. The association decided to establish such a committee on recommendations, to consist of 9 members to be elected in 1908, 3 to serve for 6 years, 3 for 4 years, and 3 for 2 years, the respective terms to be filled at their expiration for periods of 6 years. From this committee are to be organized 3 subcommittees corresponding to the present committees A, B, and C, to whom all recommendations of new methods or of changes in methods are to be submitted at least 3 weeks prior to the meeting of the association.

A further recommendation of the president, extending membership in the association to delegates from Canada and Mexico, was favorably reported, but final action on the constitutional amendments involved was deferred until the next meeting. A recommendation limiting the appointment of referees to official analytical chemists was adopted.

Resolutions were adopted in commemoration of the life and work of the late Dr. G. C. Caldwell and of Prof. W. O. Atwater, expressing the appreciation of the association of the fundamental work which they had performed as pioneers in agricultural chemistry.

The association also adopted a resolution favoring the holding of an international conference of chemists and others connected with food and drug control and with the administration of laws relating thereto, for the purpose of securing uniformity in methods.

The subject of food adulteration was, as usual, a prominent feature of the programme. E. F. Ladd submitted a paper by J. Hortvet on the examination of colors used in foods or natural to foods, and a paper by E. Gudeman on the solubilities of food colors. C. H. Jones, associate referee on saccharine products, reported that the work on this subject during the year had been confined to his personal examination of maple products of the crop of 1907.

A. McGill made a preliminary report on cereal products and E. M. Bailey submitted three methods as provisional for the analyses of cocoa and chocolate. A paper by H. L. Harris discussed legislation on preservatives in foods, with special reference to boron compounds. C. B. Cochran presented an outline for the classification of the coal-tar colors soluble in water, and W. D. Horne a method for the determination of moisture in sirup and molasses. C. A. Crampton and L. M. Tolman submitted a paper entitled A Study of the Changes Taking Place in Whiskies Stored in Wood, and G. E. Patrick a paper on the detection of thickeners in ice cream.

F. C. Weber, associate referee on the determination of water in foods, reported investigations comparing drying in a vacuum with 0.5 mm. mercury with drying in an oven with partial vacuum at 100°. T. J. Bryan submitted a paper on the carbon dioxid value of compressed yeast and of compounds of compressed yeast and starch.

The referee on nitrogen, C. L. Penny, reported cooperative work by 53 analysts in a comparison of methods of determining total nitrogen. F. C. Cook, associate referee, presented a report of cooperative work on the separation of meat proteids, and H. Snyder a report on the separation of vegetable proteids.

F. W. Woll, referee on dairy products, reported the continuation of the study of analysis of condensed milk, with special reference to the determination of lactose, sucrose, and fat in the sweetened product, considerable cooperative work being undertaken. G. E. Patrick presented two methods for cheese analysis. Feeding stuffs were reported upon by J. K. Haywood, and sugar by C. A. Browne. The work on sugar, much of which was cooperative, dealt chiefly with the analysis of dextrin and a comparison of methods for the estimation of glucose in honey. Papers were also presented on sugar and molasses by Doctor Browne and J. E. Halligan, by A. H. Bryan on the effect of hydrosulphite and rongalite on the polarization of dextrose, levulose, and sucrose, and by Fritz Zerban and W. P. Naquin on the determination of sulphurous acid in molasses.

The work on medicinal plants and drugs, submitted by the referee, L. F. Kebler, had been extended to methods for the assay of aconite leaves and root, belladonna leaves and root, cinchona bark, cocoa leaves, and colchicum crowns and seeds. F. P. Veitch, referee on tannin, reported that the work had been confined to a comparative study of the filtration of soluble solids through folded filter papers of high and ordinary grades. Cooperative work on soils was reported by the referee, J. H. Pettit, mainly in continuation of that undertaken the previous year.

The referee on inorganic plant constituents, W. W. Skinner, reported results in comparison of the determination of total sulphur by the peroxid and combustion methods. G. S. Fraps presented results obtained at the Texas Station in the study of the phosphoric acid of the soil.

The report of the referee on phosphoric acid, B. W. Kilgore, dealt with the determination of basic slag. A paper entitled Preliminary Studies on the Analysis of Basic Slag for Available Phosphoric Acid was also presented by H. D. Haskins. The associate referee, J. M. McCandless, reported results of cooperative investigations on methods for determining iron and aluminum in phosphatic rock.

A. L. Kniseley, referee on potash, and B. B. Ross, associate referee, reported that work had been restricted to a study of the volumetric method for determining potash. R. J. Davidson, referee on insecticides, submitted a report on methods for London purple, soda lime, formaldehyde, sulphur in sulphur dips, and lead arsenate. L. F. Kebler reported for the committee on testing chemical reagents, and William Frear for that on food standards.

A report on the president's address of the preceding year was presented by L. L. Van Slyke for the committee to which it had been referred, and adopted by the association.

The committee on fertilizer legislation recommended, through H. W. Wiley, that no action be taken at present toward attempting to obtain the enactment of a national fertilizer law, but that efforts be directed toward securing an agreement among State officials as to the fundamental definitions of misbranding and adulteration and as to the proper method of tagging, branding, and stating the results of analysis. Tentative definitions of these terms were submitted. It was further recommended that an attempt be made to secure agreement between the State officials and the manufacturers as to the method of referring to the crude sources of plant food in fertilizers, and that the committee be continued for this purpose with instructions to perfect, if possible, a measure satisfactory to the interests involved.

L. M. Tolman submitted a report from the committee on revision of methods. The methods as revised and compiled had been printed as Bulletin 107 of the Bureau of Chemistry, distributed to referees and others prior to the meeting, and further edited as the result of suggestions received. The methods as published in the bulletin with these corrections were adopted by the association as official and provisional. The committee was continued and further empowered to make such changes during the year as were deemed necessary, subject to the approval of the executive committee. At the expiration of the year this power is to be lodged with the new permanent committee on recommendations.

The committee on unification of terms recommended that the nomenclature now in use for fertilizers, soils, ash, etc., be retained, but that the association vote upon the advisability of permitting the use of a dual system of nomenclature when desirable, with a view to the ultimate adoption of the element system. After considerable discussion a resolution was adopted approving the attitude of the committee toward the ultimate adoption of the element system, but expressing the belief of the association that no State should discontinue the use of the terms now in vogue until the discontinuation had been approved by the association. The appointment of a committee was authorized for bringing the question of the use of the element system before the next International Congress of Applied Chemistry, with a view to securing international agreement.

Officers for the ensuing year were elected as follows: President, H. Snyder, St. Anthony Park, Minn.; vice-president, W. D. Bigelow, and secretary, H. W. Wiley, Washington, D. C.; and additional members of the executive committee, B. B. Ross, Auburn, Ala., and G. S. Fraps, College Station, Tex.

American Association of Farmers' Institute Workers.—The twelfth annual meeting of this association was held at the National Hotel, Washington, D. C., October 23 and 24. There were 131 delegates present, representing 25 States and Territories and 4 of the provinces of Canada. The convention was opened with addresses by Hon. W. M. Hays, Assistant Secretary of Agriculture, and Dr. A. C. True, of this Office.

The president, E. A. Burnett, of the Nebraska University and Station, called attention in the annual address to the importance of reviving the "artisan" spirit among farming people, and referred to the value of local organization in institute work as a means of increasing and maintaining interest by the community in rural betterment. He noted the constantly increasing difficulty in getting a sufficient number of capable institute lecturers, and referred to the establishment of movable schools as a partial remedy, in that it would provide employment for lecturers throughout the year. Federal aid he deemed of much value in helping to unify the institute systems of the different States and in collecting and disseminating information. In his opinion a material service could be rendered by the National Government in furnishing speakers for institutes, in introducing and trying out some of the newer ideas, like the traveling institute school and other forms of extension work, and making known the investigation work of this Department.

Reports were read from 25 States and Territories and 6 of the Canadian provinces. That of the Farmers' Institute Specialist of this Department showed that during the year ended June 30, 1907, 11,448 sessions of institutes had been held in the United States, with an attendance of 1,592,202 persons. Twenty-six States reported special meetings, attended by 104,224, and 6 State directors ran railroad specials, meeting 51,505 persons, making a total for the United States in attendance upon the institutes during the year of 1,747,931. The appropriation for institute purposes was $285,950. No institutes were held in Alaska, Nevada, Porto Rico, and Texas.

Reports were presented from each of the 6 standing committees of the association, and there were also papers and discussions upon the traveling library, the field institute, monthly meetings, field demonstration work, introducing courses of study in agriculture into the institute, the woman lecturer, and the annual report.

A resolution was adopted indorsing the work already done in forwarding the interests of farmers' institutes by this Department through the Farmers' Institute Specialist. The executive committee of the association was directed to confer with the Secretary of Agriculture and this Office relative to the needs of this work and to urge upon the incoming Congress the appropriation of a sum sufficient to enable the Department to develop it adequately.

The term of office of the standing committees was extended to three years, one member to be elected each year. This will make available the services of the members through a longer period and is expected to increase the efficiency of the committees. The officers of the association for the ensuing year are:

President, Dr. Tait Butler, Raleigh, N. C.; vice-president, J. L. Ellsworth, Boston, Mass.; secretary-treasurer, John Hamilton, Washington, D. C.; and the executive committee: The president and the secretary ex-officio; G. A. Putnam, Toronto, Ontario; T. L. Calvert, Columbus, Ohio, and A. E. Chamberlain, Brookings, S. Dak.

National Corn Exposition.—The first National Corn Exposition was held in Chicago October 5–19. About 5,000 exhibits of corn were shown, representing nearly every State as well as Canada. Although the attendance was somewhat disappointing, from an educational point of view the exposition was considered extremely successful. An intercollegiate match in corn judging was participated in by teams of students from the Iowa and Kansas colleges, the first prize of $200 being awarded to the Iowa College.

During the exposition a National Corn Growers' Association was organized for the purposes of encouraging the improvement of corn by breeding, disseminating information regarding the best methods of soil culture and farm management for corn, encouraging the holding of a national corn exposition annually by stimulating interest in corn culture in undeveloped territory, unifying methods and standards of corn judging so far as possible, securing the adoption of uniform classification for corn exhibits and rules governing exhibits, encouraging the development and uses of corn products, and opening up home and foreign markets through education regarding the use of Indian corn and corn products as food for man and beast.

National Dairy Show.—The National Dairy Show was held in Chicago October 10–19, with exhibits of about 600 cattle representing 6 breeds from 13 States and Canada. The exhibits of butter and of dairy machinery were also especially good. Director M. A. Scovell, of the Kentucky Station, served as judge in the Ayrshire class, and the programme included papers and addresses by E. H. Webster and C. E. Gray, of the Dairy Division of this Department; Oscar Erf of Ohio State University, G. H. Benkendorf of the Wisconsin University and Station, G. L. McKay and H. G. Van Pelt of the Iowa College and Station, J. W. Fraser of the Illinois University and Station, T. L. Haecker of the Minnesota University and Station, and H. H. Dean of the Ontario College and Station.

In connection with the show the second annual meeting of the National Association of Dairy Instructors and Investigators was held, with representatives of 10 States in attendance. An address was delivered by the president and reports received from committees on the dairy score card, official testing of dairy cows, the relation of the association to the National Dairy Show, courses of instruction, and experimental work in production and manufacture. Additional committees were appointed on official tests, standards for dairy products, cooperative work, and the formation of a cow test association.

The former officers were reelected as follows: R. A. Pearson, of Cornell University, president; Oscar Erf, of Ohio State University, vice-president, and C. B. Lane, of the Dairy Division, secretary and treasurer. The next meeting is to be held at Cornell University next summer in connection with the Graduate School of Agriculture.

Agricultural Departments in India.—An account of the work accomplished during 1906–7 in reorganizing and developing agricultural departments and educational and research institutions in India is published in *The Agricultural Journal of India* for July. It appears that the Imperial Department has engaged in training a number of men to take up responsible posts in the different provinces, that the provincial departments have made good progress toward organizing separate departments of agriculture, and that a decided advance has been made in the acquisition of material equipment.

The Agricultural Research Institute at Pusa is approaching completion and its laboratories will probably be occupied during the current year. In each province the site for a provincial college and research station has been selected, and in many cases considerable progress has been made in erecting buildings and laying out the land. The plans contemplate eight provincial colleges and experiment stations in addition to the Imperial Research Institute, besides a large number of experimental and demonstration farms. There has been delay in inaugurating field experiments at Pusa owing to the necessity of carrying on some uniform crop work for several seasons to obtain a knowledge of the character of the soil. Departments of chemistry, botany, entomology, and mycology have been organized, and in each of these some preliminary research work has been started.

Institute for Milling Research.—An institute for milling research was opened July 30 in the Seestrasse, Berlin, adjoining the present institutes for research in the sugar and fermentation industries. The institute consists of a main building with administrative offices and laboratories, an experimental granary, wheat and rye mills, and a bakery. The mills are equipped with electrical power and the most modern machinery throughout, with duplicate plants, each capable of milling 2 tons of grain per day. The bakery and granary are similarly well fitted up.

A grant of $150,000 from the minister of agriculture was available for the establishment of the institute, besides an annual grant for its maintenance. The institute is to be in charge of the Prussian Chamber of Agriculture, the German Millers' Union, and the Central Bakery Union of Berlin. It will be devoted to practical research and scientific investigations on grain during storing, milling, and baking, experiments in the baking of home-grown and imported grain, other research work for the government, and official and private analyses of grain, feedstuffs, etc.

Royal Hungarian Agricultural Museum at Budapest.—Three large exposition buildings in Budapest have recently been converted into an agricultural museum, which was opened June 9. This is one of the four large agricultural museums, comparing favorably with those at Berlin, Rome, and St. Petersburg.

New Journals.—The establishment is noted of *Southern Woodlands*, a bimonthly published by the Georgia Forest Association, with Alfred Akerman, the State forester, as editor. The initial number contains, besides brief editorial notes, the addresses of Mr. Akerman and Alfred Gaskill of the Forest Service of this Department, at the inauguration of a department of forestry in the University of Georgia.

Cornell University has discontinued the *Junior Naturalist Monthly* and is issuing the *Cornell Rural School Leaflet*. An explanation of the change is given in an article by L. H. Bailey, in which it is stated that the College of Agriculture has "always had in view the agricultural aim or application" of nature study, but that it was thought necessary first to prepare the way by encouraging work in the schools which would lead to "nature-sympathy," which "is fundamental to all good farming" and should go before any study of "the specific agricultural phases of the environment." The *Cornell Rural School Leaflet* will be published monthly under the editorship of Alice G. McCloskey, with Profs. G. F. Warren and Charles H. Tuck as advisors. The initial number contains, in addition to Director Bailey's article, a paper on Nature Study Agriculture, by Miss McCloskey, and suggestions as to equipment for teaching elementary agriculture, by Professor Warren.

The *Quarterly Journal of the Department of Agriculture, Bengal*, is being published under orders of the government of Bengal. It is stated to be intended primarily for members of the several local agricultural associations and for such members of the landholding and farming classes as take a personal interest in agricultural matters. The initial number contains reprints of department publications, extracts from other journals, and short notes on a variety of agricultural crops and allied topics.

Miscellaneous.—Dr. G. Hellmann has been appointed professor of meteorology in the University of Berlin and director of the Prussian Meteorological Service in succession to the late von Bezold.

Wiener Landwirtschaftliche Zeitung announces the retirement on account of ill health of Dr. C. Fruwirth, of the Royal Agricultural High School of Würtemberg.

Dr. Gustavo d'Utra, former director of the Agronomic Institute at São Paulo, Brazil, has been reappointed to that position and given a commission to travel in Europe and the United States for the purpose of studying the institutions devoted to agricultural education.

Deutsche Landwirtschaftliche Presse notes the resignation of P. Peterson as director of the Experiment and Control Station at Oldenburg-on-the-Main. Dr. F. Honcamp has been appointed his successor.

The National School of Agriculture, formerly located at San Jacinto, Mexico, is to be removed to a new site near the City of Mexico, where sufficient land will be provided for the use of the school and also for experimental purposes, and where suitable buildings will be erected. The control of the school has recently been transferred from the Department of the Interior to the Department of Public Instruction and the Fine Arts.

Dr. Albert E. Leach, chief analyst of the Massachusetts State Board of Health, has accepted the position of chief of the new food inspection laboratory established by the Bureau of Chemistry of this Department at Denver.

The administration building of the meteorological observatory of the Weather Bureau, at Mount Weather, Va., was burned October 23. The loss approximates $25,000, including some valuable instruments.

J. E. Roadhouse, a graduate of the University of California, a postgraduate student at Cornell University, and at present connected with the irrigation investigations of this Office, has been elected dean of faculty for the newly organized Hawaiian College of Agriculture and Mechanic Arts. It is expected that he will enter upon his duties about January 1, 1908. The last territorial legislature appropriated $25,000 for a building and for maintenance for two years. A preparatory class is to be organized next spring, and the opening of the college is planned to take place in the fall.

O

EXPERIMENT STATION RECORD.

VOL. XIX. DECEMBER, 1907. NO. 4.

The subject of the oral instruction of the farmer is commanding increased attention. It is new only in the wider scope which is being given it, and the more systematic form proposed. Already there is a widespread belief that the average man on his farm must be reached in some way if the work of the experiment stations and similar agencies is to be made fully effective. This means the living teacher, meeting him on his own ground and appealing to his practical sense by illustration and demonstration. It is a logical development of the various efforts now being made for a more rational and progressive agriculture.

A vast amount of investigation and experimentation in the different branches of agriculture is now in progress in this country. However technical some of it may appear to be in its abstract form, it is all directed ultimately toward utilitarian ends. It is intended to aid the practical farmer of to-day, as well as the prospective farmer or specialist who is studying the theory and its application. One of its most far-reaching objects is to leaven the whole mass of farmers, so that agriculture as a whole shall become a really progressive industry, carried on by well-informed and progressive men.

The accomplishment of this end is a peculiarly difficult task. The experiment stations go on collecting data which are well-nigh unbelievable as reflecting conditions of farm practice, and display much ingenuity in presenting these facts in such way as to arouse those laboring under them. They show, for example, that one-fourth of the cows in a great dairy section are profitless and should be sold to the butcher, that the average yield of great staple crops is only one-third to one-half what it should be, that soils are steadily being worn out by irrational and improvident methods, that farmers are paying large sums for patented stock feeds which they might better mix themselves, that the quality and value of fruit is greatly reduced by failure to spray, and a long list of other facts equally important to the farmer from a business point of view. But it is only as these things are brought home to the individual farmer that the teachings are applied in anything like a general way. The difficulty is to reach the large body of men effectively through the printed word.

The trouble is not that we have too little work which is on a practical basis, but that the results never reach the large body of farmers in such a way as to influence their practice. The condition is much the same the country over. Although the farmers of some classes and in some sections are more progressive and less conservative than in others, the need is generally apparent of a much more efficient means than we yet have of getting at the practical farmers through the living teacher, and thus placing them in position to profit by the results which are being secured in their interest.

A strong plea for the instruction of the great body of farmers was made by Prof. E. A. Burnett in his presidential address before the recent convention of Farmers' Institute Workers. He declared that "education upon the farm, as elsewhere, is more and more necessary if the farmer is to keep abreast with the progress of this generation, and if the rural community is to furnish the incentive for progress in country life. Agricultural progress demands, not alone that a few in a county or a township shall be successful farmers, but that every man and woman who lives out on the land shall be efficient and successful in his particular vocation."

To this end he laid special emphasis on relating the institute work to "the common man who is located upon the small farm with a limited capital and without special advantages of education," for he is the man who needs help along agricultural lines more than any other man. To him the question of profit appeals especially, and he needs to be shown how he can improve his financial condition through the use of methods which have been wrought out by successful farmers and by the experiment stations. There is no other agency now at work, he declared, which can reach this average man like the farmers' institute. "The presentation of the work of the experiment stations through bulletins and the agricultural press is effective in reaching a limited number of the intelligent class of farmers, but the promotion of any new idea, to be effective, requires a living advocate before the people."

There is much truth in this, and the "living advocate" has been the main strength of the farmers' institute. The scope of its teachings and influence, it was urged, should include all that pertains to the farmer's life as well as to his vocation—the improvement of home surroundings, construction of convenient and sanitary houses and barns, education of his children, and the development of the social life of the country. The influence which may be exerted by personal contact in arousing interest and stimulating pride in these matters was believed to be very potent. "The establishment of a well-ordered farm is generally not so much a matter of money expenditure as of sympathetic thought and discussion on these subjects."

Last year more than eleven thousand farmers' institute sessions were held in the several States of the Union, which were attended by approximately a million and a half people. More than a quarter of a million dollars annually is now expended in this line of work. These facts indicate the present extent of this movement.

But while the farmers' institute is an effective means of reaching the farmer as far as it goes, it has serious limitations in its present form. One of these is the short institute season, which makes it difficult to secure good workers. Professor Burnett urged that this campaign for the instruction of the farmers should continue throughout the year, and should be expanded into some form of extension work which would employ a body of trained men, whose work would include the carrying on of short courses in localities where they could be easily reached by the farmers. Such local short courses have been tried in a few States with marked success, and plans for movable schools have been presented by the institute specialist of this Office. More experiments of this kind will be made the present season.

Another phase of this practical assistance to the man in the field is that relating to new settlers. These constitute a special class whose needs are of a different kind from those of the established farmers. In a country like ours they are a class to be taken account of in a comprehensive scheme of oral or individual instruction.

There is a constant movement of people from the older settled parts of the country to the North, the South, and the West, to occupy new lands and assist in the development of new territory. These people come into a new environment which presents entirely different phases of farming from those to which they have been accustomed. Much can be done to assist them in conquering these new conditions and establishing prosperous farms. Aside from these, more than a million immigrants are now being brought to our shores annually, many of whom seek homes on the newer lands where the crops, the culture, and the system of management are entirely strange to them. How are the needs of these people to be met, and how is this influx to be made more efficient?

In a recent address before the National Irrigation Congress, Prof. Samuel Fortier presented figures showing that next year (1908) there will be thrown open to settlement in the irrigated region of this country about five million acres of unimproved land. Its occupation will mean one hundred thousand new settlers with their families, and to them will be presented the problem of preparing the desert for irrigation, the construction of ditches, selection and planting of crops, and proper cultivation and irrigation. Before any harvest can be obtained on this new land it will cost, on an average, over $20 an acre. The heaviest expense will come at a time when there is little or no income, and hence mistakes or bad management need especially to be avoided.

Professor Fortier argued that "if it is right and proper to employ the best engineering talent to design and supervise irrigation structures, the same necessity exists to employ men of equal skill to supervise that part which belongs to the agricultural side of irrigation;" and that from this point of view "fully a thousand skilled men could be profitably employed under the more recently built irrigation systems." These men should be familiar with both the practical and scientific phases of irrigation farming, and competent to advise in the work of converting a desert into a productive irrigated farm.

This is a matter which concerns all parties interested—the canal companies, the communities, the States, and the Federal Government, which has become a party through its reclamation work. The success or failure of these settlers in developing their lands and establishing comfortable and prosperous homes will mean the temporary success or failure of the new communities and of the irrigation systems under which they are located. "The conversion of $5 grazing land into $100 alfalfa land and $500 orchards is of vital interest to every western commonwealth, and each can afford liberal appropriations to help to produce such changes. Reliance must also be placed on Western States and Territories to maintain in the highest state of efficiency the irrigation work of western experiment stations."

Several of the Western States are extending various forms of assistance to both arid and irrigation farming, aside from the strictly experimental work they are doing. This work, with the assistance which the National Department of Agriculture is giving it, has proved extremely helpful. It does not, however, reach the individual settler except in a quite restricted way. The work for new settlers is not confined to the irrigated West. The South is inviting immigration and the conditions there present special problems.

These forms of extension work are essentially educational in character. As such they touch the work of the college on the one hand and of the experiment station on the other, but they do not fall directly within the scope of either agency, which already has its special duties. The work constitutes a separate branch of effort which stands between the station and the college, and supplements and extends the influence of both. Its duties require a special force of men who are not tied down by experimental work or a teaching schedule. In the present organization the experimental, the instructional, and the extension branches each have their own special field and functions which may be quite definitely defined.

The brunt of this outside work has hitherto fallen very largely upon the experiment stations. The organization of extension departments will greatly relieve them of this burden and allow them to confine themselves more strictly to their legitimate fields. The station should disseminate, not general information, but the results of its experiments and investigations; and its efforts in that direction will necessarily be confined for the most part to the usual channels of its bulletins and reports. The popular instruction of the farmer, on the other hand, does not stop with what is strictly new, but begins with what is new to him, and attempts to prepare him to profit by the work of the station.

The station men have of late been relieved to considerable extent of the institute work. This must necessarily be the case, and they can be expected to do less and less of this outside work. While a limited amount is often helpful in keeping them in close touch with the farmers' problems, this amount can easily pass beyond the boundaries of desirability. The correspondence of the station men is still, in many instances, very heavy and burdensome. It consists in large measure of answers to practical questions from farmers on a great variety of topics, and has often been made quite a feature. In some instances as many as three thousand letters a year have been answered by a single department of the station. These, if given conscientious attention, make large inroads upon the men's time and only incidentally and occasionally are of assistance to them in their work. Thousands of letters in reply to popular inquiries have been written out laboriously by the investigators themselves, because of the lack of stenographic assistance.

This has all been a part of a general propaganda for a more intelligent and progressive agriculture, and aside from its direct assistance has been of immense value in winning the confidence and support of the farmers and developing public sentiment. But this movement is now so thoroughly set in motion, the consulting expert and the bureau of information may well be turned over to a special agency. The aim should be to differentiate between these different classes of effort as rapidly as possible, and to conserve the time of the station men for the experimental work which is now demanding their full attention. This furnishes the foundation and is the mainstay of both the college instruction and the extension work.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The corrosion of iron, A. S. Cushman (*U. S. Dept. Agr., Office Pub. Roads Bul. 30, pp. 35, pls. 7, figs. 3*).—Some method of rendering the metal used for culverts, fence wire, and other purposes more resistant to corrosion would be of immense importance to agriculture. In the search for this, knowledge of the causes of corrosion is fundamental. The author discusses the carbonic-acid theory, the peroxid theory, and the electrolytic theory of corrosion, with experimental evidence against and in support of them.

In his opinion the electrolytic theory most satisfactorily explains the phenomenon of corrosion of iron. According to this theory rusting of iron must take place with the establishment of positive and negative spots. At the positive points iron will pass into solution and be oxidized to colloidal hydroxid form, which will migrate toward the negative point. The electro-chemical action was demonstrated by treating iron and steel with a specially prepared reagent, containing phenolphthalein, which marks the hydroxyl ions by red color at the negative points, and a trace of potassium ferricyanid, which marks the ferrous ions at the positive points by the formation of Turnbull's blue. To prevent diffusion and preserve the effects produced the reagent was prepared with gelatin, and the pieces of metal were embedded in the jelly.

Two ways by which questions attendant upon rapid corrosion may be met are suggested. One is by the manufacture of better metal, and the other by the use of inhibitors and protective coverings. Laboratory tests with the latter apparently indicate that chromic acid with its salts may, under certain circumstances, be used to inhibit extremely rapid corrosion by electrolysis.

Report on colors: The solubility and extraction of colors and the color reactions of dyed fiber and of aqueous and sulphuric-acid solutions, H. M. Loomis (*U. S. Dept. Agr., Bur. Chem. Circ. 35, pp. 51*).—The results are given of tests with a large number of coloring matters, the data being of value especially in connection with studies of coloring materials in foodstuffs and methods for their detection.

The heat of combustion of vegetable proteins, F. G. Benedict and T. B. Osborne (*Jour. Biol. Chem., 3 (1907), No. 2, pp. 119–133*).—Elementary analyses and determinations of the heat of combustion of a number of vegetable proteins are reported.

The smallest values, 5.358 and 5.359 calories per gram, were found respectively with wheat globulin and with conglutin from yellow lupine, and the highest value, 5.916 calories per gram, with hordein. In general, higher heats of combustion were observed in the materials examined which, the authors and with those having a lower oxygen content. Many irregularities in heat of combustion were observed in the materials examined which, the authors believe, are due to different proportions of the various amino acids which constitute the molecules of the different proteins. "As we have but little knowledge of the relative proportions of these amino acids in the proteins burned, we are not able yet to draw any definite conclusions in regard to these differences."

Changes in the index of refraction of glucosids and proteids induced by ferments, acids and bacteria, F. OBERMAYER and E. P. PICK (*Beitr. Chem. Physiol. u. Path., 7 (1905), pp. 331-380; abs. in Hyg. Rundschau., 17 (1907), No. 9, p. 553*).—Experiments undertaken by the authors showed that determining the refractive index of glucosids and proteids afforded a satisfactory method of studying the molecular changes brought about by cleavage agents.

Sucrase in apple pomace and cider, G. WARCOLLIER (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 18, pp. 987-990*).—Experimental data showed, in the author's opinion, that sucrase is not present in apple pomace and that pomace rich in saccharose ferments as rapidly as that which contains small quantities. The inversion of saccharose in cider is brought about by the sucrase of yeast.

The determination of nitrates by the Busch method, R. ADAN (*Bul. Soc. Chim. Belg., 21 (1907), No. 6, pp. 229-233; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 538, II, pp. 651, 652*).—The method of determining nitrates by precipitation with nitron is described and tests of the method on various samples of nitrate are reported. The results obtained by this method agreed closely with the calculated percentages. Studies of the solubility of the nitron precipitate are also reported, solubilities of from 1.35 to 2.23 per cent, as a result of prolonged washing, being found. The presence of nitrites was found to be a serious source of plus error. It is stated that a great obstacle to the general use of the method is the high price of the reagent.

On methods of determining soluble phosphoric acid in slag, E. JENTYS (*Sur les Méthodes de Dosage de l'Acide Phosphorique Soluble dans les Scories. Cracow: Imprimerie de l'Université Jagellone, pp. 27*).—The author discusses sources of error in the citric-acid method without separation of silica, as proposed by Wagner, and with separation of silica, as proposed by Loges, and reports comparative tests of these methods on 388 samples of slag of different kinds. He found that the Loges method gave uniformly lower results than the Wagner method, the average difference for all of the samples examined being 0.25 per cent. The conclusion is reached that neither of the methods is entirely satisfactory.

Methods of analysis and tests used by the chemists, P. A. YODER (*Utah Sta. Bul. 102, pp. 229-237*).—Methods of treating air samples and determining the carbon dioxid and moisture content are described, which were used in the incubation experiments noted elsewhere (p. 368).

The determination of creatin and creatinin, F. G. BENEDICT and V. C. MYERS (*Amer. Jour. Physiol., 18 (1907), No. 4, pp. 397-405*).—But little regularity can be observed in the properties of creatin and creatinin in human urine.

According to the authors' deductions from the experimental data reported, "in general the conversion of creatinin to creatin seems to be due to chemical action, or possibly to the action of enzyms in the urine. When a urine is allowed to stand, alkaline fermentation takes place, and the creatinin sooner or later almost completely disappears. Furthermore, the evidence from alkaline urines is not conclusive to show that creatin is an intermediate product. The conversion of creatinin to creatin even in the presence of chloroform and thymol shows that this conversion is not a bacteriological process. It is obvious that much experimenting must be carried out before the problem is wholly clarified. In general it would appear that there is more likely to be a complete loss of creatinin in a urine that is alkaline. Whatever the cause of the conversion of creatinin to creatin, in any determination of either of these compounds, a factor which must never be left out of consideration is that of the influence of bacteria. Consequently emphasis can not be too strongly laid upon the importance of making determinations of creatin and creatinin in urine as soon as possible after it has been voided. A preservative may delay action, but accuracy demands immediate analysis.

"Chloroform is unsatisfactory as a preservative, and even the use of thymol-chloroform does not insure the absence of the conversion of creatinin to creatin, or indeed the loss of creatinin, although all the samples of urine constantly gave an acid reaction."

Methods for the determination of creatin and creatinin in meats and their products, H. S. Grindley and H. S. Woods (*Chem. News, 95 (1907), No. 2470, pp. 145-147*). The data reported have been noted from another publication (E. S. R., 18, p. 812).

The identification of soap in zwieback, F. Schwarz and L. Hartwig (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 10 pp. 593–598*).—As zwieback extract containing soap is sometimes used in the manufacture of adulterated zwieback, the authors studied the possibilities of determining small amounts of soap in such goods.

Small quantities of unsaponified soap, they conclude, may be best extracted by means of absolute alcohol. If dilute alcohol is used, bread acids are also removed which saponify the soap. The small amount of soap used in zwieback manufacture is in general broken down into alkali and free acid by fermentation or baking processes and is not recognizable as soap in the zwieback. Goods made with extract containing soap show more alkali in the ash and more free acids soluble in alcohol and ether than ordinary zwieback. Of course the use of zwieback extract which contained potash or butter of high acid content would also affect these factors.

Identification of sodium benzoate or phosphate in the ash of chopped meat, A. Beythien (*Pharm. Centralhalle, 48 (1907), p. 122; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 10, p. 648*).—Although the sodium content of the ash was increased, the author believes that the natural variations are so great that the determination of this value will not serve for the detection of added sodium benzoate or phosphate.

Reply to criticisms of dry lead defecation in raw sugar analysis, W. D. Horne (*Jour. Amer. Chem. Soc., 29 (1907), No. 6, pp. 926–929*).—A controversial article.

The use of cryoscopy in judging of spices and other drugs, E. Beckmann (*Arch. Pharm., 245 (1907), No. 3, pp. 211–234, figs. 6*).—According to the experimental data summarized, cryoscopic methods may be of importance in judging of the quality of spices and other drugs. The data summarized also discuss the use of such methods in the estimation of fat in milk, cheese, and other foods.

The rapid estimation of total solids in milk, C. Revis (*Analyst, 32 (1907), No. 377, pp. 284, 285*).—One cc. of acetone is added to 2.5 gm. of milk in a flat porcelain dish which is placed on a water bath for 12 minutes and in a water oven for 2 hours.

The estimation of salicylic acid in milk and cream, C. Revis and G. A. Payne (*Analyst, 32 (1907), No. 377, pp. 286–288*).—The milk or cream is neutralized with sodium hydroxid and treated with hot alcohol. The filtrate from this is diluted with water and rendered distinctly alkaline. After a portion is distilled off, the residue is treated with potassio-mercuric iodid solution, filtered, and the filtrate extracted with ether. The ethereal extract is treated with tenth-normal sodium hydroxid and after the addition of an equivalent amount of sulphuric acid is used for the colorimetric determination of salicylic acid by the use of iron alum.

Refraction of nonvolatile fatty acids in butter, W. Ludwig (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 3, pp. 208–213*).—The indices of refraction of 111 samples of butter ranged from 40 to 43.6 and of the nonvolatile fatty acids from 28.9 to 31.7.

Refraction of nonvolatile fatty acids in butter, H. Sprinkmeyer and A. Fürstenberg (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 3, pp. 213–215*).—The authors determined the indices of refraction of butter, cocoanut oil, lard, and other fats, and of the nonvolatile fatty acids contained therein. Ten samples of butter showed indices ranging from 42.8 to 45, and the nonvolatile fatty acids of the butter indices ranging from 30.8 to 33.4. Similar results were obtained with other fats. The authors do not believe that the refractometer numbers of the nonvolatile fatty acids show less variations than those of the fats

Refraction of the nonvolatile fatty acids, T. Sudendorf (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 3, pp. 216–220*).—The refractometer numbers of 56 samples of butter from various sources ranged between 40.1 and 46.3 and the numbers of the nonvolatile fatty acids of the butter between 28.7 and 34.9. Determinations were also made of the indices of refraction of cocoanut oil, lard, and tallow, and of the nonvolatile fatty acids of these fats. As a means of detecting adulterations, the author finds no advantage in determining the index of refraction of the nonvolatile fatty acids over that of the fats themselves.

A new method for the detection of cocoanut oil in butter, R. Cohn (*Ztschr. Öffentl. Chem., 13 (1907), No. 16, pp. 308–311*).—The fat is saponified as in the Reichert-Meissl method, the alcohol is evaporated, and the soap is dissolved in warm water, cooled, and treated with a saturated solution of sodium chlorid. To the clear filtrate from this is added hydrochloric acid, which causes a cloudiness if cocoanut oil was present in the original sample. The amount of cocoanut oil is indicated by the degree of cloudiness.

The new "international" method of tannin analysis (*Collegium, 1907, No. 266, pp. 249–254*).—This gives the final recommendations of the international commission appointed at the 1906 conference of the International Association of Leather Trades Chemists to investigate and make comparative tests of various methods of tannin analysis with a view of selecting the most satisfactory.

An apparatus for the determination of carbon dioxid in carbonates, P. Malherbe (*Ann. Chim. Anal., 12 (1907), No. 7, pp. 261–263, figs. 3*).—An apparatus so constructed as to obviate danger of suction of the sulphuric acid into the flask where the carbon dioxid is being disengaged is described.

The rate of combustion and pressure developed in a calorimetric bomb, F. G. Benedict and F. P. Fletcher (*Jour. Amer. Chem. Soc., 29 (1907), No. 5, pp. 739–757*).—The Berthelot-Atwater bomb calorimeter was used. In this study of the effects of different amounts of material and different initial pressures upon combustion pressure, the effect of different sized capsules and of loose and compressed material, and related factors. The authors' summary of their results follows:

"With an initial pressure of 300 lbs., the pressures in the calorimetric bomb rarely exceeded 700 lbs. The greater the quantity of material the greater the pressure, although the pressure is not proportional to the weight of the substance. The greater the initial pressure the greater the maximum pressure, although regularity and proportionality are not observed.

"The medium sized capsule used in these experiments has a distinct tendency to decrease the maximum pressure and to retard combustion. The other capsules have a much less marked but similar effect. The pellet form of material in all cases markedly decreases the maximum pressure and retards the combustion.

"The incorporation of inert material is without appreciable effect on the maximum pressure, but markedly retards the rate of combustion. Anthracite coal results in low maximum pressures, but the rate of combustion is extremely slow, sharply contrasting with results from bituminous coal."

Proceedings of the twenty-second convention of the Association of German Agricultural Experiment Stations, Stuttgart, September 15 and 16, 1906, (*Landw. Vers. Stat., 66 (1907), No. 3, pp. 169–251*).—This account contains a brief report on the work and expenditures of the association during the past year; the discussion and adoption of an amended rule requiring a unanimous vote of members present for the adoption of new methods or the change of old official methods; instructions to the fertilizing experiment section to test the difference in efficiency of the nitrogen of horn meal and bone meal and the influence of the organic matter of raw bone on the action of its phosphoric acid; a second report on investigations on sulphur for use in vineyards; on steps taken to fix the limits of variation in the composition of ammoniated superphosphates; on definition of the unallowable impurities of bran and of seeds, and the allowable percentage of sand in feeding stuffs; a paper on examinations of potash salts falling below standard grade and the adoption of a resolution declaring the so-called works analyses unreliable; a report on comparative tests by a number of experiment stations of the von Lorenz method of determining phosphoric acid, especially as applied to the determination of citric-acid-soluble phosphoric acid in Thomas slag, the convention ordering a further comparison of the method with the ordinary official methods; a report on certain misunderstandings arising in the Thomas slag trade; discussions of methods of detecting mites in feeding stuffs and of determining the purity of linseed cake; and a brief account of progress made in perfecting a method of determining fat by shaking with ether.

Various other reports on matters of organization, policy, and cooperation between agricultural organizations, etc., are also included.

Proceedings of the twenty-third annual convention of the Association of Official Agricultural Chemists, held at Washington, D. C., November 14–16, 1906, edited by H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Bul. 105, pp. 213, fig. 1*).—This is the official report of the proceedings of the convention. A summarized account of the meeting has been given (E. S. R., 18, p. 396), and a circular of the Bureau containing extracts from the proceedings noted (E. S. R., 18, p. 711).

Analyses for members during 1906, J. HENDRICK (*Trans. Highland and Agr. Soc. Scot., 5. ser., 19 (1907), pp. 145–147*).—Brief notes are reported regarding the analysis of fertilizers, feeding stuffs, and miscellaneous samples.

METEOROLOGY—WATER.

Studies on the thermodynamics of the atmosphere, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bur. Doc. 372, pp. IV + 73, pls. 10, figs. 35*).—This is a series of reprints from *Monthly Weather Review* for January, February, March, June, July, August, October, November, and December, 1906, of papers discussing asymmetric cyclones and anticyclones in Europe and America; coordination of the velocity, temperature, and pressure in the cyclones and anticyclones of Europe and North America; application of the thermodynamic formula to the nonadiabatic atmosphere; numerical computations in the vertical ordinate; the horizontal convection in cyclones and anticyclones; the waterspout seen off Cottage City, Mass., in Vineyard Sound, on August 19, 1896; and the meteorological conditions associated with the Cottage City waterspout.

Meteorological Chart of the Great Lakes, A. J. HENRY and N. B. CONGER (*U. S. Dept. Agr., Weather Bur., Met. Chart Great Lakes, 1906, No. 2, pp. 12, chart 1*).—This is a summary of observations on storms and high winds in the lake region, 1906; precipitation, November, 1905–October, 1906; opening and closing of navigation, 1906; vessel passages at Detroit, Mich., during the season of navigation, and wrecks and casualties for 1906.

Meteorological Chart of the Great Lakes, A. J. HENRY and N. B. CONGER (*U. S. Dept. Agr., Weather Bur., Met. Chart Great Lakes, 1907, No. 1, pp. 29, pl. 1, chart 1.*)—This contains a summary of the average annual precipitation in the lake region and of observations on the meteorological conditions of the winter of 1906–7 in the lake region, with notes on ice on the Great Lakes during the winter of 1906–7, and display of storm warnings. Lists of stations and location of flagstaffs and steel towers, and Canadian Great Lakes storm-warning stations are also given.

Meteorological conditions at Orono, Me., J. S. STEVENS (*Univ. Maine Studies, No. 7, pp. 52, chart 1*).—This is a compilation of meteorological observations which have been carried on at Orono, Me., since January 1, 1869, including also the results of a series of special observations on precipitation and on the evaporation of snow and ice and of liquids.

Meteorological division, E. BURKE (*Montana Sta. Rpt. 1906, pp. 138–141*).—This is a record of temperature, precipitation, humidity, soil temperatures, wind velocity and direction, sunshine, cloudiness, etc., at Bozeman for the year 1906, with summaries of similar observations since January 1, 1900.

Annual precipitation in Oklahoma and Indian Territory, J. P. SLAUGHTER (*Oklahoma Sta. Rpt. 1907, pp. 60, 61*).—Tabular summaries are given of annual precipitation at various places in Oklahoma and Indian Territory during the period 1889 to 1906.

Report on meteorological observations 1906, R. H. CURTIS (*Jour. Roy. Hort. Soc. [London], 32 (1907), pp. 230–239, figs. 3*).—Observations on temperature, precipitation, wind movement, and sunshine at the garden of the Royal Horticultural Society, Wisley, during each month of the year, are summarized in notes and diagrams.

The weather of 1906 in Switzerland, R. BILLWILLER (*Schweiz. Ztschr. Forstw., 58 (1907), Nos. 2, pp. 46–54; 3, pp. 85–88*).—Monthly and annual summaries of observations on temperature, precipitation, sunshine, etc., are given for various places in Switzerland, and the general character of the weather of the year is discussed.

The unreliability of weather forecasts (*Himmel u. Erde, 19 (1907), No. 8, pp. 377–380*).—This is a critical review of an article by H. J. Klein, and tends to show that Klein's conclusions regarding the unreliability of the government weather forecasts in Germany are not well founded. The author's analysis of these forecasts during 4 months leads to the conclusion that only 10 per cent of them were bad and only one entirely wrong.

The end of weather shooting, J. M. PERNTER (*Met. Ztschr., 24 (1907), No. 3, pp. 97–102; Umschau, 11 (1907), No. 29, pp. 572–574*).—From the author's own experiments at Windisch-Feistritz and those at Castelfranco in Italy, and elsewhere, the conclusion is reached that the inefficiency of this method of protection against hail is clearly demonstrated.

Meteorology in its relation to horticulture, R. H. Curtis (*Jour. Roy. Hort. Soc. [London], 32 (1907), pp. 104–112, figs. 3*).—This is a general discussion of the meterological elements which are of most direct interest to horticulturists and the means of determining and interpreting them.

Report on the phenological observations for 1906, E. Mawley (*Quart. Jour. Roy. Met. Soc. [London], 33 (1907), No. 142, pp. 139–163, pl. 1*).—As usual in these reports the leading climatic and phenological characteristics of the different seasons of the year are described and the seasonal growth of 13 selected plants in different parts of England, Ireland, and Scotland are platted. The data used were furnished by a large number of observers throughout the United Kingdom.

The psycho-physical aspect of climate, F. Pearse (*Jour. Trop. Med. and Hyg. [London], 10 (1907), No. 14, pp. 242, 243*).—Weekly averages for 24 years of pressure, temperature, humidity, and rainfall at Calcutta are correlated with the physical sensations which the different types of weather produce.

A contribution to the climatology of the Canary Islands, O. Burchard (*Met. Ztschr., 24 (1907), No. 2, pp. 64–74, fig. 1*).—The leading climatic conditions are described with a summary of the principal meteorological data involved.

Climate of the wheat area of Central Canada (*Quart. Jour. Roy. Met. Soc. [London], 33 (1907), No. 141, p. 55*).—This is an abstract of a paper by L. W. Lyde presented at the York meeting of the British Association. It is explained in general that this area has a typical continental climate modified by latitude and lakes, a long summer day, slow rotation of earth, and chinook winds. Spring is sudden and short; summer is the rainy season, beginning with mid-May rains and ceasing with mid-August dry spell; autumn is a dry season; the winters are long and cold, but the cold is not sufficiently intense to affect the north limit of wheat in summer, although guaranteeing a cleansing of the plowed lands.

The climate of Peru, J. Hann (*Met. Ztschr., 24 (1907), No. 6, pp. 270–279*).—The climatological conditions of Peru are summarized mainly on the basis of the observations by Bailey (E. S. R., 18, p. 613) and Pickering.

The average duration of frosts on the earth, O. Dorscheid (*Met. Ztschr., 24 (1907), Nos. 1, pp. 11–24, fig. 1; 2, pp. 49–64, pl. 1*).—Data bearing on this subject from all parts of the world are summarized and discussed. A bibliography of 55 references is also given.

On the soot and smoke nuisance, M. Dennstedt and F. Hassler (*Chem. Ztg., 31 (1907), No. 43, pp. 550, 551; abs. in Chem. Zentbl., 1907, II, No. 2, p. 174*).—Analyses of 10 samples of hard-coal soot showed an average of 12.9 per cent of ammonium sulphate, the amount varying from 1.9 per cent to 26.2 per cent. The authors attribute the injurious effect of smoke and fumes mainly to the presence of free sulphuric acid.

Water resources of Georgia, B. M. and M. R. Hall (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 197, pp. 342, pl. 1*).—"It is the purpose of this publication to present in a single volume the large amount of data relating to the flow and power of Georgia streams resulting from the work of the water resources branch of the United States Geological Survey, which was begun in the year 1895. These data consist essentially of gage heights and discharge measurements that can be used to show the continuous daily flow of the streams, and of certain river profiles, in the form of tabulated elevations of water surface at points along the river, that can be used to estimate the available fall at any place. The amount of water flowing in the stream and the fall which can be used will determine the amount of power which can be developed. A quick formula to use is as follows: $\frac{\text{Flow in sec. ft.} \times \text{fall in feet}}{11} =$ net horsepower on water wheel, realizing 80 per cent of the theoretical power."

Water resources of the Kennebec River basin, Maine; quality of Kennebec River water, H. K. Barrows and G. C. Whipple (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 198, pp. VI+235, pls. 7, figs. 17*).—"A large amount of information of value in the study of this drainage basin has been gathered at various times, but much of it is scattered through various manuscripts and reports and is not readily accessible. This paper has been prepared in response to the constant demand for this information from both engineers and the public. Especial attention has been given to the subject of water storage, as this is of the utmost importance to present and future users of the water and the natural opportunities for regulating and improving flow in this basin are exceptionally good." The investigations reported were made in 1904 to 1906 in cooperation with the Maine State Survey Commission.

Surface water supply of New England, 1906, H. K. Barrows et al. (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 201, pp. 120, pls. 5, figs. 2*).—The observations reported in this bulletin are similar to those previously published as reports on the progress of stream measurements. The methods employed in making the measurements are briefly explained and records of stream flow in the principal drainage areas of New England are given.

Occurrence and use of artesian and other underground water, E. H. Sellards (*Florida Sta. Bul. 89, pp. 85–113, map 1*).—This is a preliminary report on the water resources of Florida based upon investigations made in connection with the U. S. Geological Survey and also independently by the Florida Station. A general account of the water supply is given and its usefulness for agricultural and other purposes is indicated.

The results show that Florida is abundantly supplied with water and that underground water of good quality is available for irrigating purposes in all parts of the State. Surface water occurs at varying depths in limited quantity, but artesian water occurs in abundant supply at greater depths. Flowing artesian wells occur along the coast and at very low inland elevations. The surface water is in imminent danger of contamination and ground water in limestone is also in more or less danger of contamination from natural sinks and from sewage wells. The underground waters carry considerable amounts of mineral matter in solution, but not enough to impair their usefulness for agricultural purposes.

Underground water in Sanpete and central Sevier valleys, Utah, G. B. Richardson (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 199, pp. 63+VI, pls. 6, figs. 5*).—This paper reports and discusses the results of observations on the source, distribution, recovery, and quality of the underground waters of these valleys. The data secured indicate that there is a considerable supply of underground water awaiting development in the valleys.

The composition of the waters varies with the geology of the watershed. The waters of wells of the uplands are similar in composition to that of the mountain streams of the same locality, but that from shallow wells in the lowlands, especially in irrigated districts, usually contains a large amount of dissolved salts. "The natural conditions are generally favorable for obtaining good water for domestic purposes, but the communities give little heed to the sanitary character of the water, and as a result epidemics of typhoid fever of greater or less violence are not uncommon."

The detection of pollution in underground waters, and methods of tracing the source thereof, J. C. THRESH (*Engin. News, 58 (1907), No. 5, pp. 109, 110*).—This is an abstract of a paper read before the British Association of Waterworks Engineers, which describes the use of sodium chlorid, ammonium chlorid, and fluorescin in tracing the source of pollution in wells.

The purification of sewage by peat filters, H. POTTEVIN (*Compt. Rend. Acad. Sci. [Paris] 144 (1907), No. 14, pp. 768–770*).—Experiments similar to those of Müntz and Lainé (E. S. R., 18, p. 1023) are reported.

In these experiments two earthenware cylinders 0.85 meter deep were used as the septic tanks from which the sewage was siphoned off every 24 hours upon a filter bed consisting of alternate layers of peat and chalk. Notwithstanding the fact that the experiments were made during the winter at temperatures which were not the most favorable for purification, the organic and ammoniacal nitrogen was completely oxidized in the case of sewage containing as much as 200 mg. of nitrogen per liter. The whole of the ammoniacal and organic nitrogen was not recovered in form of nitric nitrogen, but apparently a certain variable amount was lost in form of free nitrogen.

SOILS—FERTILIZERS.

The genesis of soils and the principles of a genetic soil classification, P. KOSSOVICH (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 7 (1906), No. 4, pp. 478–501*).—According to the author, the peculiarities and the character of those physico-chemical processes by which the soils were formed must be taken as a foundation for a genetic classification of soils. The soil solution is the medium in which these processes take place and, on the one hand, is determined by these processes and, on the other, influences their character by its composition; hence it follows that the nature of the soil solution must in the main determine the peculiarities and properties of the soils. The primary difference in the soil solutions which consist mainly of electrolytes is shown in the reaction of the solution which may be alkaline, neutral, or acid.

Since a neutral reaction can not long be maintained in a soil solution there exist only 2 main types of soil solution—alkaline and acid—and consequently also only 2 groups of soils. The alkaline soil formation which takes place under the influence of alkali salts of weak acids (carbon dioxid and silica) is characterized by the accumulation of bases, mainly sesquioxids, and the leaching out of silicic acid. The acid type of weathering proceeds mainly under the influence of humic acids and is accompanied by an accumulation of silica and the washing out of the bases. In the group of soils formed through alkaline weathering belong those of the deserts and steppes (chernozem), in which strong bases such as soda, potash, lime, and magnesia are present in quantities sufficient to produce an alkaline reaction in the soil solution. The group of soils of the acid type of weathering consists of the gray forest soils and the podzols which do not contain a sufficient amount of lime and magnesia to neutralize the humic acids. The eluvial soils may be distributed between these 2 types or may represent intermediate or transition forms.—P. FIREMAN.

Soil solutions: Their rôle in soil formation, methods of their examination, and their significance for the characterization of soil types, S. A. ZAKHAROV (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 7 (1906), No. 4, pp. 388–477, figs. 7*).—On the basis of a comprehensive survey of the literature and extended experiments with soils of various types, the author arrives at the following general conclusions: The soil extracts and, consequently, the soil solutions of the various soil types differ from one another in color, reaction, total content of soluble substances, and the ratio of the mineral and organic portions. Furthermore, the distribution of the soluble constituents is unlike in the different horizons as we go down in the soil.—P. FIREMAN.

Variability of the concentration of the soil solution and of the content of the soil of easily soluble compounds in dependence on external conditions, K. K. GEDROITZ (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *7* (*1906*), *No. 5, pp. 521–561*).—On the basis of theoretical considerations the author arrives at the conclusion that the total concentration of the soil solution and the concentration of individual compounds therein have no constant values, but undergo rapid changes. This conclusion he corroborates by a survey of the literature and by his own experiments. He finds the fluctuations even during short periods of time so great that it is impossible to consider the results obtained by the estimation in a soil sample of the water-soluble compounds and of the phosphoric acid soluble in acetic and citric acids at a given moment as indicative of the character of the soil.—P. FIREMAN.

Investigations on weathering processes, K. D. GLINKA (*Pochvovyedyenie* [*Pédologie*], *6* (*1904*), *pp. 293–322; 7* (*1905*), *pp. 35–62; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *7* (*1906*), *No. 6, p. 677*).—By a careful study of the weathering processes the author aims to clear up in detail the course of decomposition mainly of the aluminum silicates under various natural conditions, and to determine the character of the decomposition of these silicates when transformed into chernozem, laterite, red earth, podzol, brown laminated-columnar clay, etc.—P. FIREMAN.

Humus-carbonate soils, and their transition into podzols (Bleisand), A. F. LEBEDEV (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *7* (*1906*), *No. 5, pp. 571–592*).—The author distinguishes, first, a type of soils rich in humus, calcium carbonate, and other calcium salts (humic salts), in the upper horizon, but poor in sesquioxids and magnesia. The accumulation of silica in the upper horizon is also characteristic. Second, a type of transition of the humus-carbonate soils to the podzols, which is characterized by a complete leaching out of calcium carbonate, small humus content, an impoverishment in sesquioxids, alkaline earths, and alkalis, and an enrichment in silica. Considerable quantities of sesquioxids, alkaline earths, and alkalis are, however, found in the second horizon which forms the transition to the parent rock.—P. FIREMAN.

The geological-agronomic charting of the North German flat lands, F. WAHNSCHAFFE (*Deut. Landw. Presse, 34* (*1907*), *No. 48, pp. 399, 400*).—The agricultural features of the surveys which have been made by the Royal Prussian Geological Institute since 1873 are described. The charts prepared from these surveys show properties of the soil and the nature of the subsoil so far as it bears upon the question of the cultivation of the soil.

Soils from the Mattagami region of Canada, A. HENDERSON (*Rpt.* [*Ontario*] *Bur. Mines, 15* (*1906*), *pt. 1, pp. 151–155, fig. 2*).—Chemical analyses of 10 samples, and physical analyses of 24 samples of soil from this region are briefly reported. Somewhat less than half of its soils were clays and heavy clays. The percentage of phosphoric acid was very uniform, while that of potash varied with the amount of alumina present, and the nitrogen content was very variable. The results in general indicate that all of the soils would be comparatively easy of cultivation and show that they contain a sufficient quantity of fertilizing constituents to render them quite fertile.

The story of the soil, H. S. WILLIAMS (*Appleton's, 9* (*1907*), *No. 6, pp. 724–733*).—A popular article.

The maintenance of fertility, C. E. THORNE (*Ohio Sta. Bul. 182, pp. 131–194, pls. 5, figs. 7*).—This bulletin brings up to date the account of the investigations on maintenance of soil fertility which were last fully reported on in Bulletin 110 of the station (E. S. R., 12, p. 127).

"As at present organized, this work is being conducted at the experiment station, in Wayne County, where both field and laboratory investigations are in progress, and at the station's three test farms, viz, at Strongsville, Cuyahoga County; at Germantown, Montgomery County, and at Carpenter, Meigs County. The work on the farm of the State University was discontinued in 1900; that at East Liverpool in 1901, and that at Neapolis, Fulton County, in 1902."

The general plan of the experiments has been given in the abstracts of the previous reports referred to.

Summarizing briefly the more important results which have been obtained up to the present time, covering the 13 years, 1894 to 1906, inclusive, it was observed that in 22 of the 24 separate comparisons the complete fertilizer produced the largest total increase. In 16 of the 24 tests the combination of phosphorus and nitrogen stood second in amount of increase produced. Of the 8 exceptions in this case 5 were with crops occupying first place in the rotation crops—corn, tobacco, and potatoes—grown on sod land. "In 14 cases the combination of phosphorus and potassium occupies the third rank. In 2 cases it stands first, 4 cases second, and fourth in 3 cases and fifth in 1 crop. The fourth and fifth places are nearly evenly divided between the plat receiving phosphorus alone and that receiving potassium and nitrogen, so far as relative rank is concerned. . . .

"It is therefore evident that in all these tests, made upon soils widely different in origin, location, and previous history, and under varying systems of cropping, from a 5-year rotation on an exhausted soil with but one clover crop in each period and that usually a very poor one, to a 3-year rotation on rich land on which good crops of clover were grown every third season, it has been the complete fertilizer, carrying nitrogen as well as phosphorus and potassium, which has produced the largest increase of crop. The clover crop alone, therefore, even under the most favorable natural conditions, and when abundantly supplied with phosphorus and potassium, has not supplied sufficient nitrogen to maintain the maximum production of which the succeeding crops are capable.

"It does not follow, however, that clover growing should be dispensed with, or that the purchase of fertilizer nitrogen is recommended. On the contrary, these experiments have shown that the increased gain resulting from the addition of nitrogen to the fertilizer is frequently insufficient to justify the purchase of nitrogenous fertilizers at the present market rates, hence a cheaper source of nitrogen must be found than nitrate of soda or the still more expensive 'ammonia' of the fertilizer sack, before we can profitably reach the maximum production of our crops.

"Fortunately, such a source lies within the reach of every farmer in the form of barnyard manure."

As a general outcome of this series of experiments the author considers the following points of fundamental importance in determining the fertilizer requirements of a given crop:

"(1) The geological history of the soil upon which the crop is to be grown.

"(2) The system of cropping which is being followed and the place in that system of that particular crop.

"(3) The botanical relations of the crop itself, that is, whether it is classed with leguminous or nonleguminous plants."

A soil fertility test, G. A. CROSTHWAIT (*Idaho Sta. Bul. 59, pp. 16, figs. 5*).—This bulletin reports the results of greenhouse tests during 1906 in 4-gal. earthenware jars of typical virgin and cultivated Palouse soils.

In the fertilized series of these soils nitrogen was supplied in the form of dried blood, 15 gm. per jar; phosphorus as steamed bone meal, 6 gm. per jar;

and potash as muriate of potash, 3 gm. per jar. Kubanka durum wheat was the crop used in the experiments.

The results show that wherever nitrogen was added, whether on virgin or cultivated soil, there was a decided increase in yield, the increase being more marked, however, on the cultivated soil. Phosphorus produced a very satisfactory increase on both virgin and cultivated soils, and as with nitrogen, the increase was greater on the cultivated than on the virgin soil. Potash increased the yield to some extent, though not so much as phosphorus. Nitrogen and phosphorus combined produced a greater increase than would be expected from their effect when applied alone. It is suggested that this was due "to chemical reaction between the two fertilizers by which they were made more readily available." No considerable benefit resulted from combination of phosphorus and potash. "The use of manure gave a better result than did the use of either phosphorus or potassium, but the result was considerably less than when nitrogen was added. . . . However, the manure used was not so rich in fertility as that usually used in such experiments, much of the nitrogen having no doubt escaped."

The results in general show that the greatest need of these soils is nitrogen, and that this need increases under cultivation. It is suggested that the most economical method of supplying this need is by the culture of leguminous crops. The purchase of commercial fertilizers except in a small way to be used in testing the soil is not at present recommended.

A study of Rhode Island soil requirements by means of field tests, G. E. ADAMS (*Rhode Island Sta. Bul. 121, pp. 139–175*).—An account is given in this bulletin of 15 cooperative experiments conducted during the season of 1906 on 4 different soil types of Rhode Island, namely, Gloucester stony loam, Miami stony loam, Warwick sandy loam, and Alton stony loam, to determine the fertilizer requirements of the soils and to compare the results obtained in field experiments with those obtained on the same soils by the wire-basket method of the Bureau of Soils of this Department (see below). The crops grown were purple-top turnip in 14 trials, Swedish turnip in 7 trials, and spring wheat in 12 trials.

"From the results obtained from this series of experiments, conducted for one season, there appears to be no relation between the soil type and the plant food requirements of a given soil. . . .

"Hydrated lime often exerts an injurious effect upon certain crops, when grown upon the lighter soils, if applied immediately before the seed is sown, even though the soil reddens blue litmus paper. This caustic action upon the roots of young plants is, however, only temporary, as shown by the benefit derived from liming, by crops the seed for which was sown a few weeks after applying the lime. No appreciable difference was noted in the benefit derived from an application of the same quantity of calcium oxid, whether in the form of ground limestone or in hydrated lime."

Soil tests in paraffined wire baskets compared with tests on farms, B. L. HARTWELL and C. L. COOK (*Rhode Island Sta. Bul. 120, pp. 109–138, pls. 2*).—This is a report on cooperative experiments with the Bureau of Soils of this Department in which soils from 15 different localities in Rhode Island were tested with wheat by the wire-basket method of the Bureau "to ascertain the effects of lime, of a complete fertilizer with and without lime, and of omitting potassium, phosphorus, or nitrogen from the complete fertilizer when used with lime," and to compare the results obtained by this method with those obtained in field experiments on the same soils in place. Some of the soils were also tested by similar methods in 8-in. Wagner pots, in which the wheat was grown for a much longer period than in the wire baskets.

"As a result of the first year's experiments with the baskets, benefits resulted from liming, both with and without the fertilizer, in 11 out of the 15 experiments.

"Nine of the 11 soils which were benefited by liming produced by the basket method larger crops when lime alone was used than when the complete fertilizer was added without lime; in some cases the fertilizer gave no increase at all until the soil had been limed. This does not show, of course, that it is more economical to add lime than fertilizer; for the best crops were as a rule obtained when the two were combined.

"The practice of adding ordinary commercial fertilizers only to soils primarily in need of liming is of doubtful economy.

"Soil tests which are conducted upon land to which lime has been added just before planting may give very different results from those which would be obtained after the lime had exerted its full action upon the soil.

"In the case of soils with which the effect of lime in liberating plant-food ingredients is marked, the details of its application may be of such importance as to change the relative deficiencies of potassium, phosphorus, and nitrogen as shown in the following paragraph.

"Three soils which exhibited a lack of potassium primarily, by the first trials in the baskets, showed by subsequent trials, with new portions of the same soils, that potassium was no longer the element which was principally deficient. The same amounts of lime, potassium, phosphorus, and nitrogen were added; the difference in the two trials being in the temperature at which the soil and the added materials were allowed to remain before planting.

"The gain, by the basket method, from the addition of muriate of potash was greater when the green weights, rather than the amount of transpired water, were taken as a criterion. The acid phosphate and the nitrogenous manures did not exhibit the same tendency.

"The element which was shown by the basket method to be the most deficient one in the case of a given soil was usually found prominently, if not principally, deficient by the field test. There were, however, in many instances subordinate though quite marked deficiencies in the field which were not indicated with certainty during the short period of growth of the wheat in the baskets."

Soil biology in its relation to fertilization, J. L. Hills and C. H. Jones (*Vermont Sta. Bul. 130, pp. 213-290*).—This article attempts to present in "as readable and popular a manner as possible without the sacrifice of essential accuracy of statement . . . what is conceived to be the present understanding of soil biology as it relates to fertilization and particularly to the soil nitrogen content."

The article treats of the nature and classification of micro-organisms in general, the propagation and environment of bacteria, soil bacteria affecting mineral ingredients and soil bacteria affecting organic ingredients, the nitrogen cycle, nonbacterial nitrogen losses, and the balance of nitrogen gains and losses.

It also contains a glossary of technical terms used and a partial list of publications consulted in the preparation of the article.

The feeding of plants by the free living nitrogen-fixing bacteria of the soil, A. Koch (*Mitt. Deut. Landw. Gesell., 22 (1907), No. 12, pp. 117-121, figs. 2*).—This article summarizes briefly the results of a continuation of investigations on this subject (E. S. R., 18, p. 16), discussing the results more particularly in their practical bearings.

When sugar was added in varying amounts (20 to 80 gm. per kilogram of soil) it was found that the largest fixation of nitrogen per gram of sugar occurred in the soil to which sugar was added at the 20 gm. rate, the amount of fixation being on an average 10 mg. of nitrogen to each gram of sugar added. Practically the same rate of fixation was shown by pure cultures of Azotobacter. When the amounts of sugar were increased to 40, 60, and 80 gm. per kilogram of soil there was an absolute increase in fixation, but a steady decrease per gram of sugar. Beyond 80 gm. there was a rapid absolute decrease. Fractional weekly applications of sugar of 2 gm. each for 8 weeks gave about the same fixation as 20 gm. in one application. With 2 gm. of sugar in 18 weekly applications there was a decided decline in fixation, and the same was true in case of repeated applications of somewhat stronger sugar solutions. When, however, 18 separate applications of 20 gm. each of sugar were made there was a large absolute increase in fixation of nitrogen, amounting to 0.8 gm. per kilogram of soil.

There was a distinct loss of nitrogen when sugar was applied in March while the temperature of the soil out of doors was still low. Active fixation set up, however, when the soil was brought into a warm room.

The application of lime not only did not increase fixation of nitrogen, but in some cases actually lowered it. The injurious effect of potassium salts, especially the chlorid, was quite pronounced. On the other hand, applications of phosphoric acid very greatly promoted fixation. Carbon bisulphid did not increase fixation, and in many cases reduced it somewhat. Fixation was decidedly increased by applications of iron sulphate.

In pot experiments with applications of molasses as a cheap source of carbonaceous food for the nitrogen-fixing bacteria there was a decided loss of nitrogen, thought to be due to the fact that the molasses contained nitrogen compounds which were easily decomposed by the organisms which fed upon this nitrogen rather than upon the free nitrogen of the air. Organic matter of vegetable origin was not found in these experiments to be a good source of carbonaceous food for the nitrogen-fixing organisms.

In pot experiments with buckwheat, oats, and other crops there was a decided decrease in yield the first year when the sugar was applied in March in the open. The following year, however, there was an increased fixation of nitrogen and a marked improvement in growth and yield of crop on the soil to which sugar had been applied the previous fall, indicating that the nitrogenous matter elaborated by the nitrogen-fixing organisms is readily assimilated by higher plants, and that there was a close and direct correlation between fixation of nitrogen, nitrification, and increase of yield.

Soil inoculation by means of pure cultures, J. Vanderghem (*Bol. Min. Fomento* [*Peru*], *4* (*1906*), *No. 12, pp. 9–12*).—Inoculation experiments with alfalfa are briefly reported. Inoculation was ineffective on soil which had previously grown a leguminous crop.

On the action of the micro-organisms in rendering the potash of leucite in soils available to higher plants, S. de Grazia and G. Camiola (*Staz. Sper. Agr. Ital.*, *39* (*1906*), *No. 9, pp. 829–840; abs. in Chem. Zentbl.*, *1907*, *I*, *No. 19*, *p. 1451; Jour. Chem. Soc.* [*London*], *92* (*1907*), *No. 538, II, p. 641*).—In investigations on leucite, similar to those on insoluble phosphates already referred to (E. S. R., 18, p. 920), it was found that the amount of potash in the soil solution was greater when micro-organisms were present than when they were absent. It is suggested that the organisms absorbed and assimilated the potash and so made it more readily available for higher plants.

Experiments on the lasting effect of green manure nitrogen on light, sandy soils, C. von Seelhorst (*Mitt. Deut. Landw. Gesell.*, *22* (*1907*), *No. 14*, *pp. 139–144*).—From the results of experiments made in large casks, in 1906, the conclusion is drawn that green manures turned under in October on light, sandy soils decompose so rapidly that during the course of a mild wet winter half of the nitrogen has been removed in the drainage water by February and March. It is therefore recommended that green manures should not be turned under on such soils very far in advance of the planting of the crop.

Modern methods of promoting the rational fertilization of farm crops, E. WEIN (*Jahrb. Deut. Landw. Gesell., 22* (*1907*), *No. 1, pp. 26–41*).—A general discussion of this subject.

Fertilizers, D. W. MAY (*Porto Rico Sta. Circ. 6, English and Spanish eds., pp. 16*).—The general principles underlying the use of natural manures and commercial fertilizers with special reference to Porto Rican conditions are explained, with more specific directions regarding the use of fertilizers on cotton, tobacco, sugar cane, citrus fruits, and pineapples.

Fertilizer experiments on peat soils continued for 16 years, H. VON FEILITZEN (*Svenska Mosskulturfor. Tidskr., 21* (*1907*), *No. 2, Bilaga, pp. 199, 212*).—The experiments have been conducted at Tobo, Sweden, since 1891, on a marsh soil (*starrtorf*) with clay subsoil, the former containing 3.41 to 4.75 per cent lime, 2.23 to 2.86 per cent nitrogen, 0.06 per cent potash, and 0.07 per cent phosphoric acid (in extract). The fertilizers applied during the series were mostly Thomas slag in varying amounts, with potash and nitrate. The results show the beneficial effect of an annual fertilization with both phosphoric acid and potash on the yield and quality of the hay crop for meadows on good and well-cared-for peat land, and that the land can be kept in grass for a long series of years by this system. The trials also furnish evidence that a liberal fertilization of phosphoric acid and potash pays especially well on account of the after-effect which can be observed from the same for many years afterwards.—F. W. WOLL.

Fertilizer experiments with nitrogen in different forms and amounts, CLAUSEN (*Deut. Landw. Presse, 34* (*1907*), *No. 30, pp. 248, 249, fig. 1*).—Comparisons of nitrate of soda and sulphate of ammonia on moor, sand, and loam soils are reported.

The effect of ammoniacal and nitric nitrogen on the development of corn, M. SOAVE (*Ann. R. Accad. Agr. Torino, 48* (*1906*); *abs. in Staz. Sper. Agr. Ital., 39* (*1906*), *Nos. 10–12, pp. 1100–1105*).—Experiments in nutritive solutions and in soils are reported which confirm the general belief that ammoniacal nitrogen must be first transformed into nitric nitrogen before it can be assimilated by the maize plant.

Studies on the value of calcium cyanamid as a nitrogenous fertilizer, A. MÜNTZ and P. NOTTIN (*Ann. Inst. Nat. Agron., 2. ser., 6* (*1907*), *No. 1, pp. 145–183*).—After a brief review of the more important literature relating to the preparation and use of calcium cyanamid, the authors report the results of their own laboratory and culture experiments with this material.

The use of the Kjeldahl method for determining the nitrogen in calcium cyanamid is recommended, complete reduction being brought about in one-half hour. Comparative tests of the rate of nitrification, by the Müntz and Girard method, showed that the amount of nitrogen nitrified in 5 months was in the case of ammonium sulphate 100 per cent, calcium cyanamid 88 per cent, dried blood 66 per cent, and roasted leather 26 per cent. The low rate of nitrification was due to the fact that the application of the cyanamid in the amounts used in these experiments (10 and 20 times that used in practice) retarded nitrification and even resulted in denitrification at the beginning. When applied in normal amounts or in large amounts fractionally nitrification was apparently not interfered with and was practically as active as in the case of ammonium sulphate.

The experiments indicated that the retarding effect of calcium cyanamid on nitrification is not due (or only in minor degree) to the caustic lime present, but to the cyanamid itself. It was also observed that larger applications of the cyanamid could be used on soils rich in humus without retarding nitrification than on those poor in humus.

A sample of cyanamid kept exposed to the air from November 21 to June 15 increased in weight from 100 to 120.3 gm., and its nitrogen content decreased from 20.07 per cent to 15.96 per cent, due to escape of ammonia. There was no loss in 42 days when cyanamid was mixed with kainit. When mixed with superphosphates the temperature of the mixture rose perceptibly, and there was an immediate loss of about 5 per cent of the original nitrogen. When stirred up with water and allowed to stand for a long time there was a gradual loss of nitrogen.

Applications of 200 kg. per hectare of cyanamid had no effect on earthworms. Experiments with a large number of different kinds of crops on a great variety of soils and under different climatic conditions indicate the cyanamid to be fully as effective as ammonium sulphate as a fertilizer, and that it does not retard germination or suffer loss in top-dressing when used in normal amounts. It may be considered the equivalent of ammonium sulphate when used in equal amounts and applied in the same manner.

Experiments in fertilizing rice with calcium cyanamid, A. Menozzi and E. Grüner (*Ann. Ist. Agr.* [*Milan*], *6* (*1901–1905*), *pp. 51–77; abs. in Staz. Sper. Agr. Ital.*, *39* (*1906*), *No. 10–12, pp. 1132–1134*).—In the experiments reported calcium cyanamid gave almost as good results as ammonium sulphate.

Investigations on the action of lime niter, A. Stutzer (*Jour. Landw.*, *55* (*1907*), *No. 1–2, pp. 69–77; abs. in Jour. Chem. Soc.* [*London*], *92* (*1907*), *No. 538, II, p. 646*).—Pot experiments with neutral and basic lime niter on oats, fodder beets, and potatoes are reported, showing about the same effect from the two materials. The results with potatoes were especially favorable and superior, as regards both yield and starch content, to those obtained with sodium nitrate. On fodder beets the medium and heavier applications of lime niter (58 to 116 lbs. per acre) were as a rule fully as effective and in some cases more effective than sodium nitrate. The poor development from other causes in the case of the oats made the results inconclusive. The neutral lime niter used in these experiments contained 25.8 per cent of lime and 12.47 per cent of nitrogen. The basic material contained 43.7 per cent of lime and 10.56 per cent of nitrogen.

The future of the manufacture of nitrogenous fertilizers from the air, Maizières (*Engrais*, *22* (*1907*), *No. 22, pp. 516, 517*).—A statement is given showing the works which have been or are being established for the manufacture of calcium cyanamid in different countries of the world.

An agricultural problem (*Tradesman*, *57* (*1907*), *No. 9, p. 63*).—Reference is made in this article to the purpose of a hydro-electric power company in Tennessee to undertake the manufacture of calcium cyanamid.

Investigations on the combustion of elementary carbon and nitrogen. Berthelot (*Compt. Rend. Acad. Sci.* [*Paris*], *144* (*1907*), *No. 7, pp. 354–357; abs. in Bul. Soc. Chim. France*, *4. ser.*, *1* (*1907*), *No. 11, p. 608*).—A study of the decomposition of cyanogen by means of the electric spark is reported, from which the conclusion is drawn that there is no stable equilibrium between pure nitrogen and carbon.

The electro-chemical problem of nitrogen fixation, P. A. GUYE (*Monit. Sci., 4. ser., 21 (1907), I, pp. 225–236; abs. in Chem. Zentbl., 1907, I, No. 23, p. 1647*).—The general problem is stated and the Frank-Caro and electro-chemical processes are discussed.

The author believes that the problem of electro-chemical preparation of nitric acid will only be completely solved when methods of liquefaction of the air and the separation of its constituents have been perfected. The solution of the problem also depends upon the production of cheap electrical power from coal. The author estimates the present cost per pound of production of nitric nitrogen to be 11.4 cts. in form of lime niter, and 10.5 cts. in form of nitric acid assuming the cost of power to be $10 per kilowatt year. His estimate of the cost per pound of nitrogen in the form of cyanamid varies from 12 to 14 cts.

The fixation of the nitrogen of the air and lime niter, A. RIGAUT (*Rev. Sci. [Paris], 5. ser., 7 (1907), No. 25, pp. 778–780*).—The cost of the production of nitrates from the nitrogen of the air by electrical processes and the agricultural value of the product so obtained are briefly discussed mainly on the basis of a recent article by Guye noted above.

The use of feldspathic rocks as fertilizers, A. S. CUSHMAN (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 104, pp. 32*).—The importance of potash as a constituent of fertilizers, the occurrence of potash in nature, the availability of the potash of ground rock, the effect of fineness of grinding, cost of ground feldspar, and extraction of potash from ground feldspar (E. S. R., 18, p. 717) are discussed and the literature of the subject reviewed. A limited number of greenhouse and field experiments in which fine ground feldspar was used on tobacco are briefly reported.

The general conclusion reached is that "systematic and long-continued experimentation is the only possible method of obtaining conclusive information on the subject. The evidence so far obtained appears to indicate that under certain conditions and with certain crops feldspar can be made useful if it is ground sufficiently fine. On the other hand, it is highly probable that under other conditions the addition of ground feldspar to the land would be a useless waste of money. At the present stage of the investigation it would be extremely unwise for anyone to attempt to use ground rock, except on an experimental scale that would not entail great financial loss. . . .

"It is extremely unlikely that ground rock will ever entirely displace the use of potash salts, for its availability must inevitably depend upon many modifying conditions, such as the nature of the soil, the amount of moisture present, the character of the other fertilizers used, and the varying root action of different crops. With tobacco the results so far obtained have been encouraging, but it is possible that this plant, which is a voracious feeder, can make use of the potash in fine-ground feldspar to a greater extent than other fast-growing crops, such as potatoes and the cereals, some of which mature in practically 60 days and must therefore find their plant food in a highly available condition."

Influence of calcium carbonate on the development of yellow lupine in podzol (Bleisand) soil, A. F. KHANDURIN (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 7 (1906), No. 6, pp. 667–676, figs. 10*).—The author found that calcium carbonate is useful for the development of lupines in the early stages of their growth but injurious at later stages. The carbonate interferes with the full development of the root tubercles, whose function in supplying nitrogen is of greater importance in the later stages of the growth of the lupines.—P. FIREMAN.

Analyses of commercial fertilizers, B. L. HARTWELL ET AL. (*Rhode Island Sta. Bul. 122, pp. 177–187*).—"This bulletin contains the analyses of such potato and vegetable fertilizers found on sale in the State in the spring of 1907 as had been licensed at the time the manuscript was sent to press. A second bulletin, to be published later in the season, will contain a report on the other fertilizers which have been and may yet be collected and examined."

Commercial fertilizers, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul. 130, pp. 155–212*).—This is a report on inspection of fertilizers offered for sale in Vermont during the spring of 1907. Of 129 brands examined, 77 per cent met their guaranties, and the quality of the crude stock used in manufacturing the fertilizers seemed on the whole to be satisfactory. The average selling price of the fertilizers was $30.57, the average valuation $21.21. As in previous reports a comparison is made of analyses of certain brands during 5 years.

Ready reckoner fertilizer chart, O. THACKER (*Columbus, Ohio, 1906, pp. 44*).—This book gives tables for finding the price of fertilizers at different ton prices ($10–$29), when put up in bags of different sizes.

AGRICULTURAL BOTANY.

Studies in plant regeneration, ELSIE KUPFER (*Mem. Torrey Bot. Club, 12 (1907), No. 3, pp. 195–241, figs. 13*).—Experiments were made with budless portions of roots, stems, leaves, inflorescences, and fruits to determine their powers of regeneration, the subjects of the experiments being for the most part flowering plants.

The results obtained demonstrated that every part of the plant, even when preformed rudiments were absent, had some power of regeneration, although in a majority of cases it was not complete enough to establish a new plant.

Among the author's conclusions it is stated that the disposition to form roots is much more generalized throughout the plant and more easily energized than the power to form shoots.

Experiments showed that regeneration is dependent upon an adequate food supply. In plants from which the reserve food had been exhausted by a prolonged exclusion from the light, no regeneration took place if the parts were subsequently darkened, or if carbon dioxid was absorbed from the atmosphere in which they were kept.

Certain parts of plants failed to regenerate one or the other kind of organs when each of the conditions assigned as causes of regeneration had been fulfilled, and it seems necessary to assume the existence of specific substances which are responsible for the formation of those organs. The author believes that different enzyms which are localized in definite parts of a plant are responsible for this regeneration, and a series of experiments has been inaugurated to test this assumption.

Physiologically balanced solutions for the growth of plants, O. LOEW and K. ASO (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1907), No. 3, pp. 395–409, pl. 1*).—Experiments were carried on with different solutions to determine the effect of the one-sided nutrition of plants.

It was found that physiologically balanced solutions are fundamentally important to the best development of higher plants. For lower forms of algæ and fungi balanced solutions were not necessary. Potassium sulphate and nitrate proved injurious to plants when their concentration was abnormally high. Potassium salts were found to retard, but not prevent the toxic effects of magnesium salts, and the cause of the retardation to be entirely different from the prevention of this toxic action by calcium salts.

Observations on the stimulation of plant growth, S. KAKEHI and K. BABA (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1907), No. 3, pp. 455, 456*).—The authors conducted a series of experiments with peas and barley to test the effect of manganese carbonate as a stimulant to plant growth. The chemical was found to exert a moderate stimulation on peas and less upon barley.

In a second series of experiments with wheat comparisons were made between manganese sulphate and sodium fluorid, and it was found that in addition to the stimulating effect of both chemicals, manganese sulphate produced much better results than sodium fluorid.

The physiological rôle of phosphoric acid in the nutrition of plants, Gabrielle Balica-Iwanowska (*Bul. Acad. Sci. Cracovie, 1906, pp. 616–642; abs. in Jour. Chem. Soc.* [*London*], *92* (*1907*), *No. 535, II, p. 386*).—In plants germinating in a liquid free from phosphoric acid an increase of mineral phosphorus was found to take place at the expense of organic phosphorus compounds. The phosphorus thus separated from the organic compounds is not utilized for the reproduction of organic phosphorus compounds when no further amount of phosphates is supplied. When plants are deprived of phosphoric acid a portion of the organic phosphorus compounds formed previously in the plant is decomposed, as in the case of the germinating seeds.

Under normal conditions barley plants transform relatively small amounts of phosphates into organic compounds up to the time of flowering, the change being chiefly made during the production of seed. At this period the nucleo-proteins migrate toward the grain, and during ripening a portion of the phytin separates from the protein compounds.

The effect of acids and alkalis on chlorophyll, R. Willstätter and F. Hocheder (*Liebig's Ann. Chem., 354* (*1907*), *No. 2, pp. 205–258, fig. 1*).—While there have been many studies made on the effect of the alkalis and acids on chlorophyll, the authors claim that none show the changes in structure and composition of the chlorophyll molecule. According to them, chlorophyll is a very complex magnesium compound.

The first effect of acids upon chlorophyll is said to be the elimination of the magnesium. The molecule of chlorophyll after reacting with the acid is an ester without basic or acid properties. The effect of alkalis on chlorophyll is the saponification of the esters, an alcohol, $C_{20}H_{40}O$, being formed while the magnesium in the molecule remains. The alcohol formed is called "phytol" and is said to be present in the chlorophyll of all plants.

The ascent of water in trees, A. J. Ewart (*Proc. Roy. Soc.* [*London*], *Ser. B, 79* (*1907*), *No. B 533, pp. 395, 396*).—An abstract is given of a paper presented by the author in which he offers evidence to show that the ascent of water in trees is a vital problem depending upon conditions which can only be maintained in living wood. He concludes that the living cells in tall trees continually restore the conditions for the ascent of water wherever these are affected by the excessive emptying of the vessels, and decrease resistance to flow, as far as possible, by maintaining continuous water columns in portions of the wood. So long as these conditions are present a pumping action only becomes necessary in trees over 20 to 50 meters in height, but suspended columns can not be maintained for any length of time in the vessels of tall trees without the aid of the living cells of the wood.

The nature of enzyms, H. E. and E. F. Armstrong (*Proc. Roy. Soc.* [*London*], *Ser. B, 79* (*1907*), *No. B 533, pp. 360–365*).—The authors summarize some of the more important views relating to enzyms and call attention to some of the principal issues which remain to be determined. According to their view, the action which an enzym exercises is specific; that is, it is limited to compounds of a particular type to a greater extent than has hitherto been recognized.

The enzyms of yeast, amygdalase, R. J. Caldwell and S. L. Courtauld (*Proc. Roy. Soc.* [*London*], *Ser. B, 79* (*1907*), *No. B 533, pp. 350–359*).—In a study of the enzyms of yeast the authors have separated a new enzym to which the name amygdalase is given. They state that the hydrolysis of amygdalin is due to a hitherto unrecognized constant of yeast which is the active agent in separating the glucose. This enzym was separated by a system of extraction at different temperatures, and its characteristics are described at length. It appears to be equally well extracted from dried yeast at temperatures from 15 to 45° C., and while a small quantity can be obtained at zero temperature, the amount may be greatly increased by heating for a short time to 45°.

The action of naphthalin on plants, K. Aso (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1907), No. 3, pp. 413–417, pl. 1*).—On account of the recommendation that naphthalin might be used to prevent attacks of nematodes, bacteria, etc., the author carried on some experiments to test the influence of naphthalin in cultures containing barley, peas, buckwheat, millet, and rice.

It was found that naphthalin could prevent the development of various soil bacteria, although it did not kill them. In the proportion of 0.005 to 0.01 per cent added to the soil naphthalin caused a moderate stimulation with barley, buckwheat, and millet, but not with peas and rice. An increase to 0.05 per cent injured the growth of all the plants. The injurious action is attributed to the vapors of the naphthalin spreading through the soil, and since it injures plants it can not be recommended as a remedy against nematodes, at least not in greater quantities than 0.005 per cent of the soil.

The accumulation of arsenic in the fruit of certain plants, B. Gosio (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 15 (1906), I, pp. 730–731; abs. in Centbl. Bakt.* [etc.], *2. Abt., 18 (1907), No. 22-23, pp. 724, 725*).—The author grew in boxes two squash plants, which, after they had attained a length of 1 meter, were regularly watered with arsenic water of a strength of 1 part metallic arsenic to 1,000,000 of water After one month the strength of the arsenic water was increased to 1 part in 100,000 and a month later to 1 part in 10,000. This was used to water the plants until their growth was completed.

Leaves, stems, flowers, and fruits were analyzed for arsenic, and it was found most abundant in the fruits, where it was present as metallic arsenic to the extent of 0.0041 per cent. By gradually accustoming the roots to the effect of arsenic the author believes even greater amounts would probably be stored up.

Causes of injury to vegetation near a large industrial establishment, P. Frazer (*Bi-Mo. Bul. Amer. Inst. Min. Engin., 1907, No. 15, pp. 377–434, figs. 2*).—By means of experiments with saturated cloths, analyses of plants, and the quantitative determination of sulphur in the air, the author has proved that the injury to vegetation was due to the gases given off by a large establishment. Studies were also made of the soot and dust driven out from smokestacks and their effect on plant growth. A bibliography, with synopses of conclusions, of a number of important contributions to the literature of this subject is given.

FIELD CROPS.

The importance of nitrogen in the growth of plants, T. F. Hunt (*New York Cornell Sta. Bul. 247, pp. 179–203, figs. 3*).—The thesis of this bulletin is that the amount of water soluble nitrogen occurring in the soil at a critical time in the plant's life history may be a limiting factor in the growth of the crop. With reference to this point the importance of nitrogen in the growth of plants, the difference between nitrogen and other elements, the function of nitrogen, the relation of total and water-soluble nitrogen, the purpose of cultural methods, the conservation of moisture, and the results of diffeernt experiments considered as bearing on this subject are discussed. The discussion on the influence of early and late spring plowing on corn production and the factors influencing the supply of water in the soil are based on the work of M. Quiroga (E. S. R., 16, p. 356).

In considering the influence of weeds the experiments of Cates are quoted, which show that plats on which maize was grown with rye, millet, and weeds contained less moisture than maize plats kept cultivated, and that the yield of ear maize was much greater where weeds were not allowed to start until June 27 instead of on June 14, although the difference in the percentage of moisture in both series of plats was nearly the same. Determination of water-soluble nitrogen in parts per million of dry soil here quoted indicate a great decrease in the water-soluble nitrogen where the weeds grew and the land was not stirred, as compared with plats which were stirred and no weeds allowed to grow. The results of another test described in this connection show that plats scraped to prevent the growth of weeds but not stirred yielded nearly as well as those that were stirred thoroughly in removing the weeds, while the yield of grain was greatly reduced on plats on which weeds were allowed to grow after the first cultivation. The author considers the results as suggesting that the failure of the maize to properly develop was due to other causes than lack of water or available nitrogen. The influence of weeds as determined by Hosford is also outlined.

Plats varying from quite a sandy loam to a clay loam, with the soil moisture ranging from 10.6 to 17.8 per cent, varied in yield of green maize fodder from 731 to 1,001 lbs. Other experiments quoted show that the growth of millet or weeds greatly checked the growth of maize, the yield of green substance where millet was sown being only one-tenth and where weeds were allowed to grow only one-fifth of that grown under ordinary cultivation, and that the total green product produced on the weedy plats was much less than on those cultivated in the usual way. It is also pointed out that the percentage of moisture was only slightly less on weedy than on cultivated plats. The question is asked as to whether the growth of maize was checked by the diversion of some of the water to the weeds and two reasons are given for believing that while the available water may have been a factor in this respect there must have been some other influence also. Thus the total product was not so great on the weedy plats as on the cultivated plats, and it is entirely probable that although in a dry season all the plats would have had a lower percentage of water the cultivated plats would have produced more maize than the weedy plats produced this year.

A table is given showing the water-soluble nitrogen in parts per million of dry soil on a cultivated plat and on a millet plat at different dates, and also on a plat to which nitrate of soda was applied. It is pointed out that on July 2 the cultivated maize plat contained 96 parts of water-soluble nitrogen per million of dry soil, while the maize and millet plat contained only 10 parts. The maize where millet grew was of a lighter green color and smaller size than where it was grown by itself, and it was reasoned that the addition of nitrate of soda should cause the maize to recover its green color and grow more rapidly than maize and millet not so treated. For this purpose twice the amount of nitrate of soda necessary to supply 86 parts per million of dry soil was applied to 35 hills of a maize plat on July 6, 14, 21, and 27. On July 14 both the maize and millet were much greener than the rest of the plat not so treated, and on July 18 the hills were distinctly larger than the untreated hills of the millet plat and as green as the plants on the cultivated plat. It was found that between July 30 and August 16 the water-soluble nitrogen increased from 160 to 320 parts of NO_3, while all the nitrate of soda was applied some time previous to the first date. The application of the nitrate doubled the growth of the crop, while the percentage of water in the soil remained the same. It is pointed out as most likely that the decrease in growth in the first instance was due in part to a lack of water-soluble nitrogen, and that the subsequent increased growth was due directly to the nitrogen applied and that it served as plant food. The results are taken as suggesting that weeds by taking up a portion of a small amount of nitrogen just at the critical period of the plant which is being cultivated may cause the injury so commonly observed.

A series of observations on alfalfa made at the Cornell Station (E. S. R., 17, p. 1059) and bearing on the subject under discussion are reviewed. "When nitrate of soda is added to the soil, as repeatedly shown in the investigations at this [Cornell] station and elsewhere, part of the nitrogen is fixed in the soil and a part of it goes into solution. What probably happens is that as the soil is exhausted of its water-soluble nitrogen by the paint, a part of this fixed nitrogen goes into solution. The behavior of nitrate of soda when applied to soils strongly indicates this action. What probably happens is, that when nitrate of soda is applied more nitrogen keeps going into solution, at just the time when the plant is making great demands on the soil for this nitrogen, than when nitrate of soda is not added."

On the assimilation of the elements of nutrition by plants during different periods of their growth, H. WILFARTH ET AL., trans. by B. L. EMSLIE (*London [1907], pp. 72, pls. 2*).—This is a translation from the German of an article already noted (E. S. R., 17, p. 856).

Report of the royal Bohemian agricultural academy at Tábor, 1906, T. ERBEN ET AL. (*Ztschr. Landw. Versuchsw. Osterr., 10 (1907), No. 4, pp. 411–430*).—A brief review of the year's work at the school is given. Variety tests are reported of 30 varieties of winter wheat, 10 of spring wheat, 10 of rye, 38 of barley, 29 of oats, 200 of potatoes, and 3 of fodder beets.

The best yields of grain from among the winter wheat varieties were secured from Cimbal, Kirsche, and Strube. The results with barley again showed the superiority of the well-selected common strains, as compared with sorts derived from Chevalier and Imperial barleys. The highest grain yields were obtained from Nolč Bohemia and Hanna from Proskowetz. Svalöf Hannchen, Primus, and Nolč Early ranked first in starch content. The lowest protein content was shown by Hannchen and Nolč J. 16 and J. 19. The best yield of oats were secured from Svalöf Goldregen, Hwittling, and a number of newly bred varieties such as Leutewitz Yellow, Strube Schlansted, and Kirsche Prolific. Of the different potato varieties under test, Director Nydrie, Prof. Nilsson, and Brocken led in starch production, with 4,950, 4,558, and 4,747 kg. of starch per hectare.

The average yields of 3 varieties of fodder beets were as follows: Eckendorf Red 369.3 kg., Eckendorf Yellow 354.8 kg., and Red Mammoth 338.1 kg. per are.

Tests of nitrate of soda and liquid manure as fertilizers for sugar beets were made, the results indicating that the use of liquid manure, while not producing as large yields as nitrate of soda, is more economical. The method of fertilization had apparently no influence on the quality.

In cooperative tests with 5 varieties of winter wheat, an average yield of 2,482 kg. per hectare was secured. The squarehead varieties survived the winter well and ranked first in yield, while Landas Gigantea stood last.

The yields in cooperative tests with oats were as follows: Duppau 3,167, Strube Schlandsted 3,119, Svalöf Ligowo 3,013, and Heraletz Late 2,930 kg per hectare.

The leading potato varieties were classified according to their quality as follows: Nilsson, Maincrop, and Sophie as excellent; White King, Gryf, and

Yellow Pearl as good; and Irene and Brocken as medium. Nilsson and Sophie are considered excellent table varieties, White King a good general variety, and Brocken and Gryf good sorts for starch manufacture. In a second potato experiment it was observed that Up-to-Date and White King are badly attacked by rot, while Walküre, Stella, Svatováclavské, and President Ascher are quite resistant to rot. Nilsson, Iduna, Walküre, and President Ascher were found to be prolific table varieties, and Up-to-Date and White King good yielding general sorts.

Baking tests with the flour of different varieties of wheat were conducted, and it was determined that the best variety in the collection was a cross by Rimpau of a very early American variety with Squarehead.

Arid farming investigations, W. M. JARDINE (*Utah Sta. Bul. 100, pp. 129–156*).—The work reported in this bulletin is with but few changes a continuation of previous experiments (E. S. R., 16, p. 862). The results secured with different crops at the various farms are tabulated. In many instances wide variation existed from year to year with the same varieties grown upon the same farms, as well as in the yields on different farms.

In the winter wheat experiments the two complete failures recorded are from 2 spring varieties of durum wheat, Black Don 8232 and Pellessier 7785. These two varieties, however, show great promise of developing into excellent fall varieties. Turkey wheat led all other varieties tested for any one year on the different farms, with a yield of 33.9 bu. per acre, and also gave the highest average yield on 3 out of the 5 farms on which it was grown. Lofthouse, Gold Coin, and Koffoid are popular and excellent drought resistant varieties.

It was observed that the number of kernels per ounce of wheat varies materially with the rainfall. On the Iron County farm, where the precipitation was very light, wheat showed from 10 to 20 kernels per ounce more than the same varieties grown on the Juab County farm, where the average rainfall was from 2 to 3 in. greater, and it is pointed out that seeding at the rate of 2 pk. per acre of the wheat produced on the Iron County farm would probably mean as many kernels per acre as seeding at the rate of 3 pk. per acre of the wheat produced on the Juab County farm. The results of sowing fall wheat at different times indicate that on the Iron and Washington county farms the sowing should be done from September 15 to October 1, on the Juab County farm from October 1 to 15, and on the San Juan farm from September 1 to 15.

Spring varieties of wheat yielded from 5 to 20 bu. per acre less than the fall varieties grown under the same conditions. The leading variety according to yield was Romanow, producing 26.66 bu. per acre in 1905 on the San Juan farm. Mohammed ben Bashir 7792, a durum wheat, gave the best average yields for the 3 years grown, 12.4 bu. per acre on the Juab farm. Other promising spring varieties for dry farms are Kahla 7794, Medeah 7594, both durum wheats, and William Fife, a soft wheat.

Oats were sown about April 15 with a press drill at the rate of 4 pk. per acre, and the field harrowed thoroughly two ways when the crop was about 3 in. high. The plants grew from 18 to 36 in. high. Black American gave the best average yield for the 3 years, averaging 31.7 bu. per acre. The best yield in any one year, 36.81 bu. per acre, was secured from Sixty Day, which, however, gave an average yield of only 22.62 bu.

Among the varieties of barley, California led in average yield with 24.3 bu. for the 3 years, and also produced the highest yield, 34.9 bu., in any one year. California Prolific and Success also gave very good yields, and the results as a whole are taken as indicating that barley can be considered one of the promising dry farm crops, especially where the annual precipitation exceeds 14 in.

Corn yielded 25.93 bu. on the Iron County farm in 1904, being the highest yield of any crop grown on that farm during the 3 years. In 1906 over 4½ tons of fodder were secured on this same farm, but the frost came before the corn matured. On the Washington County farm the highest yield produced in the 3 years was 24.7 bu. of ears and 1,936 lbs. of stover in 1906.

The following yields of alfalfa were secured on the Juab farm in 1905: Turkestan 1,500 lbs. of hay, Sand 2,050 lbs., seed from irrigated native crop 2,330 lbs., and seed from native dry land crop 2,300 lbs. On the Iron County farm, where the rainfall was low, plats containing one plant per square foot gave the best yields, 620 lbs. air-dried hay per acre in 1906. The use of 8 lbs. of seed per acre gave the best average results. Very little difference was noticeable between early and late spring seeding. The use of the press drill upon a well-prepared seed bed is recommended.

A number of varieties of grasses have also been tested on these dry land farms. After a good preparation of the seed bed, brome grass at the rate of 40 lbs., tall oat grass and orchard grass, each at the rate of 25 lbs., and Giant rye grass and bunch grass, each at the rate of 12 lbs. per acre, were sown about April 15, 1904. Orchard grass failed to produce a crop. Brome grass led on the 5 farms, with a yield of 1,895 lbs. of hay and 465 lbs. of seed per acre for the Juab County farm in 1906, 1,600 lbs. of hay for the Iron County farm in 1905, 1,800 lbs. for the San Juan farm in 1906, 801 lbs. for the Washington County farm in 1906, and 700 lbs. of hay on both the Sevier and Tooele farms in 1906. Tall oat grass ranked next in yield. Giant rye and bunch grass, two native species, were grown only on the Sevier farm, at an elevation above 7,000 ft. Giant rye produced per acre 650 lbs. and bunch grass 550 lbs. of hay in 1906, both outyielding brome grass and tall oat grass.

The yields of rye on three of the farms varied during the 3 years from 4.52 bu. per acre to 20.6 bu. On the San Juan farm emmer yielded 16 bu. per acre in 1905 and 31 bu. in 1906. A yield of 13.5 bu. per acre is recorded for field peas, 124 bu. for potatoes, and 3,531 lbs. per acre for turnips.

The tabulated results of a plowing test show that the highest yield of wheat obtained on any of the farms was 32.6 bu. from a plat on the Juab farm plowed 5 in. deep. The highest average yield for 3 years, 21.68 bu., was also obtained from land plowed 5 in. deep, while the highest average yields on the Sevier and Washington County farms, where the precipitation was very light, were 7.19 and 7.25 bu., respectively, on land subsoiled 20 in. deep. The advantage from deep plowing and subsoiling is apparently dependent upon the season and upon the soil and general climatic conditions of the section in which it is practiced. Where the annual precipitation fell below 12 or 13 in. very low yields were secured even on summer fallow, yet in most instances where the rainfall exceeded 15 in. summer fallow gave the best yields. With reference to the distribution of the rainfall, it is believed that it is almost necessary to have at least 4 in. of the annual precipitation during the growing period.

Dry farming in the Great Basin, C. S. Scofield (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 103, pp. 43, pls. 4, figs. 8*).—This bulletin gives a general description of the region, reviews experiments in dry farming as carried on by private parties and by the State of Utah on its arid experiment farms, and considers the local conditions which affect dry farming, together with the methods of interseason tillage and the crops grown.

Dry farming in the Great Basin is limited at present almost entirely to Utah, where it has been carried on since 1875 and where the practice has been increasing rapidly since 1900. In this region the precipitation comes during the autumn, winter, and spring months, while on the dry lands east of the Rocky Mountains it comes during the summer. Farming is successfully carried on with an annual average rainfall of about 15 in. Clean summer fallowing and cropping the land every alternate year, together with thorough tillage, are considered the basis of successful dry farming in this section. The most important crops grown are wheat and alfalfa, and thin seeding is found essential to the best results. Under the best methods of tillage the land apparently remains highly productive, even where no other crop than wheat is grown. At present dry farming is used only as a supplement to irrigation farming and its independent extension is considered as depending upon the development of underground water for domestic use.

Agronomy department, A. ATKINSON (*Montana Sta. Rpt. 1906, pp. 158–167*).—The average results of a 2 years' test with 23 varieties of barley showed that Guy Mayle, a dark kerneled hulless variety, gave the largest yield. New Zealand, a 2-rowed high-grade brewing barley, stood second. The hulless varieties produced the largest quantity of feed. The 2-rowed varieties gave much larger yields than the 6-rowed varieties, and in the 6-rowed sorts large yields of grain were associated with large yields of straw. The average results show a yield of 1.26 lbs. of straw for each pound of grain in the 2-rowed varieties, 1.31 lbs. of straw to each pound of grain in the 6-rowed varieties, and 1 lb. of straw to each pound of grain in the hulless barley. Early maturing varieties gave in general light yields.

The average results of 2 years' test with 23 varieties of spring wheat are reported. Glyndon 692, a red milling wheat, stood first with a yield of 57 bu. per acre. This variety, together with Glyndon 650 and Glyndon 715, was originated by the Minnesota Experiment Station and all appear to be valuable for Montana. Wild Goose, of Canadian origin, stood second with a yield of 55.7 bu. and seems to be well adapted to both dry and irrigated lands. In yield of grain the common milling wheats and the durum varieties were about equal, while spelt and emmer, which are referred to as feeding wheats, gave much lower yields. The common wheats produced the most straw and spelt and emmer the least. The durum wheats were the quickest in ripening and gave the greatest weight per bushel.

Of 34 varieties of oats Progress, Swedish Select, and Siberian, as in earlier experiments, were the highest yielders. The varieties tested had an average of 24.75 per cent of hull, being over 5 per cent below the average of varieties generally grown. Salzer Big 4 had as low as 20 per cent of hull, while Sparrowhill had 29.8 per cent.

Seed of Reid Yellow Dent corn from northern Iowa was planted from May 12 to 16 on different farms in the Yellowstone and the Bitter Root valleys. Some ears showed almost perfect maturity by October 10. Seed was selected for next year's planting. It is believed that this variety can be perfectly acclimated in from 3 to 5 years.

Alfalfa was grown with and without a nurse crop. The first year oats used as the nurse crop yielded 83 bu. per acre, but no hay was made on any of the plats. The second season the yields of alfalfa hay were practically identical on the different plats, so that up to this time the value derived from the nurse crop is limited to the yield of oats secured the first year.

Experiments with Indian corn, forage crops, leguminous crops, J. H. SHEPPERD and O. O. CHURCHILL (*North Dakota Sta. Bul. 76, pp. 339–376*).—Over 120 varieties of corn have been under test. Of 22 varieties grown for several years, N. K. & Co. fodder corn ranked first as to fodder with a yield of 9,224 lbs. per acre, and Dutton first as to ears with a yield of 2,640 lbs. per acre. The average yield of all the varieties was 5,431 lbs. of fodder and 2,069 lbs. of ears. The early varieties gave as large yields as the late ones, and the large fodder varieties did not surpass the early maturing sorts. The fodder varieties did not produce mature enough ears to permit of harvesting them separately any season during the 6 years' experiments. The smaller acclimated varieties like Gehu, Mercer, Golden Dent, and others made a more rapid and stronger growth during the early part of the season than the large fodder corns. The results with varieties of sorghum, cane, Kafir, and broom corn during 12 years show that they are not as valuable a crop for fodder production as the common varieties of Indian corn.

Shallow cultivation gave an average yield for 6 years of 35.4 bu., as compared with 34.5 bu. for shallow early and deep late cultivation, 31.5 bu. for deep early and shallow late cultivation, and 30.3 bu. for deep cultivation. In every year the corn on the plat receiving shallow cultivation was ripest when frost came, When drilled in 6 in. drills, planting on May 27 and June 9 gave better average yields than planting June 19 and 30. Corn drilled in 42 in. drills did not give such high yields as corn drilled in 6 in. drills, but it was more easily harvested and it also produced a considerable part of its value in the ears which it formed. In a test with planting different numbers of kernels per hill it was observed that the yield of fodder increased with the thickness of planting, while the greatest yield of ears was made by the plat having 4 stalks per hill. Corn drilled 6 in. apart led in average yield of fodder for 8 years with 7,843 lbs. per acre, while corn planted in drills 42 in apart led in yield of ears with 25.2 bu. per acre, the corn being in the hard dough to ripe condition when harvested.

A comparison of different distances between kernels of corn in rows 44 in. apart shows that stalks growing at intervals of 6 in. gave better returns of both ears and fodder than when grown at greater distances, the yield decreasing regularly as the distance widened. Of corn fodder grown in 6 in. drills cattle consumed during a 32-day feeding test 92.6 per cent of the forage offered them, while of the fodder grown in rows 42 in. apart only 82.8 per cent was consumed. Analyses made of fine and coarse corn fodder showed but little difference in the value of the refuse rejected by the cattle, although that from the thick grain sample was slightly superior. Corn grown in 6 in. drills produced 8,174 lbs., and that grown in 42 in. drills 5,570 lbs. per acre.

In brief notes on different crops it is recorded that field peas in 1906 yielded 31.5 bu. per acre, and that cowpeas and soy-beans had not given much promise. A heavy dressing of decomposed barnyard manure on brome grass seeded in 1902 gave a yield of 2.75 tons of hay per acre, as compared with 1.96 tons for the check test. It is believed that the reduced yields of brome grass after it has stood for a few years is due as much to the reduced fertility of the soil as to the density of the sod. Grimm and Turkestan alfalfa have produced on an average for 5 years 5,051 lbs. of hay per acre. The average yield for 7 years of medium red clover from the first cutting was 3,547 lbs. The plat giving the highest yield of red clover seed lacked only 4 lbs. of making 2½ bu. of seed per acre. Clover sown with and without a nurse crop showed no differences during any period of the following growing season.

Alfalfa in Maryland, C. W. Nash (*Maryland Sta. Bul. 118, pp. 291–314, figs. 7*).—General directions for the culture of alfalfa in Maryland are given, and the results secured in cooperative tests with farmers are summarized. The reports received show yields ranging from 2½ to 7 tons per acre. One farmer reported a yield of 5 tons per acre on a field of 66 acres seeded 12 years ago. The results of inoculation tests showed the value of using alfalfa and sweet clover soil for this purpose.

Of the farmers reporting, 122 had good stands at the time of making their reports while 36 had been unsuccessful. Of the successful parties 91 used manure, 66 lime, 57 commercial fertilizer, 39 commercial fertilizer and lime, 52 manure and lime, 33 manure and lime and commercial fertilizer, 7 a nurse crop, 41 soil inoculation, and 82 seeded in the fall.

Indian corn, its production and improvement, G. A. Crosthwait (*Idaho Sta. Bul. 57, pp. 59, pls. 11*).—This bulletin, a treatise on corn culture, discusses corn culture, seed corn, and corn improvement, together with the work in this line carried on at the station. The selection and preservation of seed corn and the methods of making germination tests are described, and the rules of exhibiting corn in Idaho, the score card, and the rules of judging are given in detail. The varieties of corn tested at the station from 1904 to 1906, inclusive, are enumerated, and the progress of the work in selecting strains adapted to Idaho conditions is mentioned.

The selection of seed corn, C. G. Williams (*Ohio Sta. Circ. 71, pp. 8*).—This circular discusses the selection of seed corn with reference to the time of selection, condition of the plant, weight, length and position of the ear, and its care after gathering.

Selecting seed corn in the fall before the crop is harvested is advised. In the experience of the station, seed selected from plants where the stand and other environment was normal gave an average yield of 3.23 bu. per acre more than seed selected in the ordinary way, and heavy weight seed ears exceeded medium weight seed ears in yield by 5.9 bu. per acre, while medium long seed ears exceeded medium short seed ears by 4.85 bu. per acre. It was observed that vigor of plant, as shown by ability to stand upright, is hereditary. Ear rows growing side by side gave a variation of from 0 to 56 per cent of broken plants.

Descriptions and classification of varieties of American upland cotton, J. F. Duggar (*Alabama College Sta. Bul. 140, pp. 142, pls. 36, figs. 35*).—For the purpose of classification the short staple or upland varieties of cotton are grouped as follows: Cluster varieties, or Dickson type; semi-cluster varieties, or Peerless type; Rio Grande varieties, or Peterkin type; King-like varieties, or King type; big boll varieties, or Truitt type; long limb varieties, or Petit Gulf type; intermediate varieties, or various types; and long staple upland varieties, or Allen type. Each one of these groups as well as a long list of individual varieties is described. Tables are given showing the number of bolls required to make 1 pound of seed cotton, the arrangement of varieties according to percentage of lint, and the weight of 100 seeds.

In experiments on productiveness, among the varieties tested at the station for a considerable number of years, Peerless, Peterkin, Russell, and Truitt have frequently stood near the top of the list. Of those tested only a few years, Cleveland, Cook Improved, Jackson, Layton, Pullnot, and Toole have given good results.

Sea Island cotton: Its culture, improvement, and diseases, W. A. Orton (*U. S. Dept. Agr., Farmers' Bul. 302, pp. 48, figs. 13*).—This bulletin discusses the geographical distribution of Sea Island cotton in the United States, the ideal crop requirements, the possible extension of the Sea Island cotton-producing area, markets, farm practices, cultivation, fertilizers, preparation of the land, seed selection, handling the crop, and the diseases and insect enemies which commonly attack the plant.

A, B, C of cotton planting, D. Morris (*Imp. Dept. Agr. West Indies, Pamphlet 45, 1907, pp. 98, figs. 5*).—This is an enlarged edition of a former publication on this subject, previously noted (E. S. R., 16, p. 152).

Bermuda hay (*Oklahoma Sta. Rpt. 1906, p. 21*).—Experiments at the station with Bermuda grass have shown that this species is not only adapted to pasture but is also of value as a hay crop. Two and one-half acres of upland soil planted to hardy Bermuda grass June 29 and 30, 1905, produced at the rate of 5.08 tons per acre from three cuttings in 1906.

Growing and curing hops, W. W. STOCKBERGER (*U. S. Dept. Agr., Farmers' Bul. 304, pp. 39, figs. 20*).—This bulletin considers the conditions essential to hop growing, and the propagation, planting, cultivating, pruning, harvesting, curing, baling, and marketing of the crop.

Trials of oats, J. SPEIR (*Trans. Highland and Agr. Soc. Scot., 5. ser., 19 (1907), pp. 177, 178*).—The 3 varieties tested in 1905 gave the following yields: Potato, 54$\frac{4}{40}$ bu., Universal, 59$\frac{3}{40}$ bu., and Wide Awake, 74$\frac{31}{40}$ bu. per acre. The different varieties are briefly described.

Experiments in crossing potatoes, J. H. WILSON (*Trans. Highland and Agr. Soc. Scot., 5 ser., 19 (1907), pp. 74–92, figs. 16*).—Discussions are presented on certain botanical features of the potato, the deterioration of varieties, variation, fruiting, and the production of seedling potatoes, together with notes on grafting and crossing.

The author secured crosses of British Queen and Myatt Kidney, New Zealand Red variety and Myatt Kidney, and Maincrop and New Zealand Red variety, the last-named in each case being the pollen parent. *Solanum commersoni* was crossed with the ordinary potato, but the resulting fruits were seedless.

Sugar beets, V. K. CHESNUT (*Montana Sta. Rpt. 1906, pp. 135–138*).—Coöperative culture tests with sugar beets were made in the Gallatin Valley and analyses of 39 samples showed an average sugar content in the juice of 16.9 per cent, a purity of 84.05 per cent, and an average weight per beet of 29.6 oz.

Comparative results from European and American beet seed showed that the beets from American seed ranked among the first in sugar content and purity.

Seedling canes and manurial experiments at Barbados, 1904–6, J. P. D'ALBUQUERQUE and J. R. BOVELL (*Imp. Dept. Agr. West Indies, Pamphlet 44, 1907, pp. 133*).—The seedling and other canes grown in these experiments were grown on 13 estates situated in typical localities on the island, 11 of the plats being on black soils and 2 on red soils. On the black soils, as plant canes, D. 95 gave the best results, yielding 9,216 lbs. of saccharose per acre, as against 6,876 lbs. from White Transparent. D. 95 was followed by B. 1529, B. 147, D. 1438, B. 376, and B. 208 in the order named. On the red soils, as plants and rattoons, B. 1566 led in yield with 9,811 lbs. of saccharose per acre, as compared with 6,199 lbs. for White Transparent. B. 376, D. 95, B. 208, and B. 1529 also gave good results.

For the years 1900 to 1906, B. 1529, B. 147, and B. 208 gave the highest returns as plants on the black soils, the increase representing $17.64, $5.37, and $4.29 per acre, respectively, as compared with White Transparent. As plants and rattoons taken together, B. 208 averaged 5,339 lbs. of saccharose per acre, as against 5,029 lbs. from White Transparent. On the red soils, as plant canes, B. 1566, B. 1529, and B. 208 gave the best results. As plants and rattoons taken together, B. 1566 and B. 376 gave increased values per acre of $22.52 and $10.86, respectively, as compared with White Transparent.

The results of the fertilizer experiments indicate, in general, that larger yields are obtained by supplementing an ordinary application of barnyard manure with commercial fertilizers than by applying manure alone, and also that an application of nitrogen both to plant canes and rattoons gives a profitable increase in yield. The results with potassic and phosphatic fertilizers were not in accordance with previous years, the application of superphosphate giving a slightly increased yield, while the potash fertilizers did not prove profitable.

The estimation of cane crops, C. H. HAMAKERS (*Internat. Sugar Jour., 9 (1907), No. 102, pp. 287–291*).—A cane field of about 2.5 acres, cut up into 100 rectangles by intersecting irrigation canals, was used for the experimental estimation of its yield. Each of the rectangles was 24 ft. long and contained 15 rows of cane. In each of these the diameter of 10 adjacent cane stalks was determined in centimeters, and with these results as a basis the yield was calculated.

It was further found that a fair average could be deduced without measuring so many stalks, the difference between the approximate and the true averages of the diameter of the stalks not exceeding ½ mm.

In the application of the system the number of cane stalks per acre is estimated by counting the stalks in a few of the 24-ft. plant rows, and by measuring the average height of the stalks at a point where the stalks are erect. In this way it is considered possible to obtain a fairly accurate estimate of the weight of the crop.

The relation of the composition of the leaf to the burning qualities of tobacco, W. W. GARNER (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 105, pp. 27*).—In summarizing the results obtained by different investigators in their studies of the burning qualities of tobacco, it is pointed out that only two facts have not been disputed, the one that chlorin injures the fire-holding capacity and the other that potash favors this property. These two facts are insufficient to explain the differences in the burning qualities of tobacco, and the author in his experiments worked with a view to determine the effects of sulphates and phosphates and the relative value of the different salts of potash in promoting the fire-holding capacity.

The tobacco samples, all of which had been thoroughly fermented, were extracted with various solvents and the effect on the burning qualities noted. In various samples extracted with petroleum ether and with ordinary ethyl or sulphuric ether the burning quality was not appreciably affected, and the same result was secured when strong alcohol was used as a solvent, except in one case where the fire-holding capacity was considerably improved by the extraction.

It is pointed out that the active principle or principles imparting fire-holding capacity to the leaf can be extracted with water, and that the problem is narrowed down to the determination of the composition of the extract and the discovery of which of the constituents contribute to the burning qualities. With this object in view, 100 gm. of tobacco having a good burn was extracted with 1 liter of distilled water, the extract being poured off and the tobacco again extracted with the same quantity of water for 24 hours longer. The principal constituents of these extracts were the chlorid, sulphate, nitrate, citrate, and malate of potassium, together with ammonium and nicotine salts and small quantities of lime and magnesia. An examination of the ash of the extracted tobacco showed that practically all of the phosphoric acid, about one-half of the magnesia, all of the oxalic acid, and the greater portion of the lime remained in the leaf, while the extract contained nearly all the chlorid, all the potash, and the malic, citric, and nitric acids, and most of the sulphuric acid. About one-half of the total ash was extracted from the leaf by this process, and this seemed to contain all the constituents imparting to the tobacco its fire-holding capacity.

An extract of tobacco having poor burning qualities was prepared in the same way. This also showed the power of imparting fire-holding capacity, but as nearly as could be determined this power was only about one-fifth of that of the other extract. The extract from the poorer tobacco contained about 5 times as much sulphuric acid, twice as much magnesia, and considerably less nitric acid than the extract from the tobacco with good burning qualities. "The total quantity of potash was about the same in the two extracts, so that the extract from the tobacco with poor burning qualities contained much less potash in combination with the organic acids. The difference in composition of these extracts, then, obtained from tobaccos having good and bad burning qualities, indicates that the principal factor favoring the burn is the potash in excess of the amount required for combining with the mineral acids."

The effects of potassium, calcium, magnesium, and mineral and organic acids of the ash on the burning qualities are discussed and the character of the ash, together with the relation of organic constituents to the burning qualities, is described.

In the summary of his work the author points out that the fire-holding capacity is dependent primarily on the content of potash combined with organic acids; that lime in general does not affect the fire-holding capacity, but is an essential factor in the production of good ash; that large amounts of magnesia tend to injure the capacity for fire-holding; that chlorin injures the burning qualities, but seldom is present in sufficient quantities to do any serious harm; and that sulphates in general injure the burning qualities, but that the effects are less marked when all the sulphuric acid is combined with potash. It is further pointed out that so far as known none of the organic constituents of tobacco, with the possible exception of the so-called tarry acids and the albuminoids, exert a very important influence on the burn.

"From these conclusions it appears that the principal objects to be attained in efforts to improve the burning qualities of tobacco by breeding and by improved methods of production, especially in the use of the proper fertilizers, are (1) a relatively high content of potash combined with citric and malic acids, with a minimum amount of inorganic salts, especially chlorids and sulphates; (2) a moderate content of lime; (3) a comparatively small percentage of magnesia, and (4) a low content of organic nitrogenous compounds, more especially the albuminoids or proteids."

The improvement of fire-cured tobacco, G. T. McNess, E. H. Mathewson and B. G. Anderson (*Virginia Sta. Bul. 166, pp. 191–234, figs. 8*).—This bulletin is based on the results of cooperative work of the Virginia Experiment Station and the Bureau of Soils of this Department. The plan of the experiment as well as the results for 1904 have already been noted from another source (E. S. R., 18, p. 235). The cultural history of the dark shipping type of tobacco in Virginia, the climate and soil required by the crop, and the results of experiments made in 1904–1906, inclusive, are discussed, and the methods of cultivating and handling dark tobacco which the investigators found to be best in their general experience as well as in their experimental work are described.

The work was carried out on 3 one-acre plats. Plat No. 1 received 400 lbs. of factory mixed fertilizer containing 12 lbs. each of ammonia and potash and 36 lbs. of phosphoric acid. Plat No. 2 was treated with 850 lbs. of a home mixture furnishing 73.5 lbs. of ammonia, 57 lbs. of phosphoric acid, and 75 lbs. of potash, and plat No. 3 was given 1,700 lbs. of a home mixture supplying 153 lbs. of ammonia, 106 lbs. of phosphoric acid, and 125 lbs. of potash.

In the fall of 1904 the plats were sown to rye as a winter cover crop. On the 2 heavy fertilized plats the rye had grown too tall for turning under, and hence rye hay was made before plowing. Owing to good moisture conditions, early transplanting, a healthy continuous growth, and the improvement in soil fertility resulting from the more intensive methods employed, good yields were secured in 1905. Plat No. 1 yielded 842 lbs. of tobacco, produced at a cost of $45.04 and sold for $60.13. Plat No. 2 produced 1,296 lbs. of tobacco and 1,000 lbs. of rye hay, at a cost of $68.47, which sold for $104.61; while plat No. 3 yielded 1,527 lbs. of tobacco and 2,000 lbs. of rye hay, produced at a cost of $90.77 and selling for $134.59. Disregarding the rye crop, plat No. 1 showed a profit of $15.19, plat No. 2 of $36.34, and plat No. 3 of $40.42, as compared with $4.64, $19.94, and $28.41, the profits, respectively, the year before.

The following season winter wheat grown as a cover crop was plowed under early in May. The amount of vegetable matter turned under on plats Nos. 2 and 3 was several times greater than on plat No. 1. The season of 1906 being wet, subsoiling 6 to 10 in. deep after plowing 6 in. deep produced no effect. The crop grew with much promise until the middle of August, when continued wet and cloudy weather caused the leaves to speck badly and very much reduced the yield and quality of the tobacco. It was observed that on the heavy fertilized plats the leaves did not speck more and the lower leaves showed a lesser tendency to yellow than on the lighter fertilized plat. This year plat No. 1 yielded 529 lbs. of tobacco, produced at a cost of $39.03 and selling for $34.15. Plat No. 2 yielded 922 lbs., at a cost of $60.15 and selling for $59.91, while plat No. 3 produced 1,305 lbs. of tobacco at a cost of $83.49, which sold for $85.37. These poor results were entirely due to the unfavorable weather conditions.

In view of the results of the three years' work, the Virginia Station and the Bureau of Soils "feel justified in asserting that under proper conditions it will be of financial benefit to the farmers in the dark belt of Virginia to use fertilizers much more liberally on their tobacco than they have been accustomed to do. . . . A soil suitable for growing a fairly good quality of tobacco should be chosen. It should possess reasonably good depth and mellowness, so as to be easily tilled, and have a proper water-holding capacity. . . . Good cultivation and handling are also necessary to make a success of a tobacco crop."

The cultivation of turmeric (*Oil, Paint and Drug Reporter, 71 (1907), No. 22, p. 29*).—Brief directions are given for the culture of this crop, and its market value is discussed.

Swedish plant breeding at Svalöf (*Svensk Utsadesförädling På Svalöf. Goteberg, 1907, pp. 94, pl. 1, figs. 49*).—A detailed description of the Swedish plant breeding station at Svalöf and of the methods in vogue at the institution.

HORTICULTURE.

Horticultural department, R. W. FISHER (*Montana Sta. Rpt. 1906, pp. 142–154*).—The results are here given of the work conducted during the year, including data on fruit-thinning experiments and variety and cultural tests with vegetables, ornamental trees, and shrubs.

The experiments to determine the relative value of thinning fruit on apple trees (E. S. R., 18, p. 441) were continued during the year, but owing to the uniformly light crop the results obtained did not show a very material increase in the size of the apples. In one orchard the cost of thinning the fruit on 12-year-old Wealthy trees was 2⅘ cts. per tree, or $2.52 per acre. When the apples were harvested there appeared to be no difference in the size or color of the fruit from thinned and unthinned trees. In another orchard in which the trees were larger and produced a heavier crop than in the first case the cost of thinning fruit was 4⅗ cts. per tree, or $5.40 per acre. The thinning in this orchard increased the size of the fruit about 10 per cent, and on trees very heavily loaded is said to have made the fruit of a marketable size where otherwise it would have been too small.

As a result of the experiments thus far conducted by the department and from the experience of fruit growers throughout the State, the conclusion is reached that it pays to thin the apples on trees which are heavily loaded. Thinning increases the size without decreasing the total weight and also prevents mechanical injury to the tree by distributing fruit more evenly. The experience of many successful fruit growers has determined that it is best to thin when danger of severe frost has passed and before the fruit has grown larger than a hazelnut, although the author believes that thinning should be done more or less throughout the growing season.

The results from the variety tests with beans are tabulated, showing the varieties grown, the yield and quality of each variety, and the dates of picking, with the total weight of the crop. The largest yields of snap beans were produced by the Long Yellow Six Weeks, Goddard, Early Mohawk, and Golden Wax. Of the green snap beans the varieties of best quality regardless of yield were Long Yellow Six Weeks and Longfellow; of the Yellow or wax snap beans, the Valentine wax and the Keeny Rustless Golden wax. Early Warwick was the earliest variety tested, producing the first snap beans.

The results secured with cabbages are also tabulated. The varieties producing the largest yield of good quality, solid heads, and of late keeping were Acme Flat Dutch, Danish Round Head, Danish Ball Head, and Succession.

With tomatoes a table is given showing the varieties ripening the first fruits and the amount of ripe and green tomatoes produced during the season on both pruned and unpruned plants. Burpee Earliest Pink gave the largest amount of ripe fruit before the plants were killed by frost. Except in 2 cases the plants pruned to 1 stem produced a much larger amount of ripe tomatoes than the plants not pruned. The varieties yielding the largest amount of ripe tomatoes of good quality were Sparks Earliana, Earlibell, and Burpee Earliest Pink, which varieties also ripened the first fruits and are recommended for early planting in high altitudes in Montana.

The work with onions conducted at the station has been published in bulletin form (E. S. R., 18, p. 39).

A large number of ornamental trees and shrubs secured from this Department, various State experiment stations, and other sources have been tested on the station grounds, and a table is given including the scientific and common names, with notes on the hardiness of each variety. There is also a separate list of those plants which have proven hardy in the trial nursery.

Report of the horticulturist, F. GARCIA (*New Mexico Sta. Rpt. 1906, pp. 44–55*).—An outline is given of investigations conducted during the year, together with tabular data on commercial fertilizer tests with onions, and notes on cultural tests with Irish and sweet potatoes and peanuts.

The results of the fertilizer experiments with onions are considered unsatisfactory since the crop suffered from adverse weather conditions. It appears from the work with Irish potatoes that they are not adapted to valley conditions in New Mexico. The sweet potato tests have given satisfaction although the crop suffered from scarcity of water and a severe hailstorm. The yield from 1.53 acres was 7,081 lbs. and the cost of digging and hauling $5.60.

Second annual report of the Ontario vegetable growers' association, 1906 (*Ann. Rpt. Veg. Growers' Assoc. Ontario, 2 (1906), pp. 68*).—This report consists chiefly of a collection of papers and prize essays on the culture of different varieties of vegetables, together with the discussions following.

Melon culture, F. GARCIA (*New Mexico Sta. Bul. 63, pp. 38, figs. 10*).—This bulletin contains popular directions for the cultivation of watermelons and canteloupes in New Mexico, together with the results of investigations with these crops at the station. A discussion is given of the soil, methods of planting, cultivation, irrigation, and harvesting, together with notes on insects and diseases and their control.

The experiments conducted at the station consisted of variety and cultural tests. The cost of production, exclusive of the cost of seed and picking, was $18.40 per acre for watermelons and $16.69 for muskmelons. Phinney Early, Cuban Queen, Mammoth Iron Clad, Gypsy or Rattlesnake, and Florida Favorite were the most satisfactory varieties of watermelon in the test. The Rockyford is the most satisfactory general purpose canteloupe, although the Netted Gem, Osage, Netted Nutmeg, and Hackensack are also considered quite satisfactory.

First report on the fruit experiments at Pusa, A. HOWARD (*Agr. Research Inst. Pusa [India], Bul. 4, 1906, pp. 40*).—During the past season a series of experiments was begun at the Agricultural Research Institute at Pusa for the purpose of obtaining information with regard to the growth and management of fruit trees. This report deals with the first year's work, including an account of the establishment of the orchard, and an outline of the experiments in progress.

Lists are given of all the fruit varieties in the experimental orchards, including citrus fruits, peaches, plums, custard apples, loquats, guavas, mangoes, figs, bananas, pomegranates, and litchis, together with a row of mixed trees of several other varieties of fruits. Plans are given of the different orchard plats, together with brief notes on the experiments to be undertaken, these to consist of variety and cultural tests and experiments in planting, pruning, and weathering.

In the case of the citrus fruits a series of stock experiments is also being conducted to determine the effect of different stocks on the development of the plant and the character of the fruit.

Marketing Hawaiian fruits, J. E. HIGGINS (*Hawaii Sta. Bul. 14, pp. 44, pls. 8*).—The station has undertaken experiments to determine what fruits can be successfully shipped to the mainland, as well as to investigate methods of packing and shipment and to introduce new kinds of fruit into the market. This bulletin contains a report of experimental shipments of pineapples, avocados, and papaias made in August, 1906.

The pineapples included in these experiments were secured from 2 of the leading growers, part coming from the lower, dark-colored soils and the remainder from the higher red lands. The fruits of one lot were gathered July 29 and allowed to cure for a day before packing. All the other fruits were gathered on July 29, packed the same day, and shipped the following morning from Honolulu. Nearly half of the shipment was subjected to fumigation with formaldehyde gas in order to determine its effect on the arrest of the development of fungi in the fruit. From a portion of the fruit the bracts were removed and the remainder was shipped with long stems. A part of the fruit was wrapped in paper with the ends closed and the rest with the ends open. Various sized crates were used and part of the shipment was placed in transit in the "'tween decks" and part on the main deck. The shipment started from Honolulu on August 1 and arrived in Portland, Oreg., on August 9, when the fruit was inspected.

The results are tabulated and are summarized in substance as follows: With regard to the use of excelsior as compared with hay as a medium of packing, both the fumigated and unfumigated stock carried much better in the hay. In both the fumigated and unfumigated stock the results are very markedly against the practice of pulling off the bracts. The fruit shipped with long stems gave much better results. Fruit wrapped in paper with the ends closed and those with the ends open gave practically the same percentage of loss in the case of unfumigated stock and a reduction in loss as compared with the check lot of 10.8 per cent. With the fumigated stock the loss was much greater in the case of fruits wrapped with paper in which the ends were closed. This is attributed to the inability of the fumes of the formaldehyde to reach the fruit. The fruits which were allowed to cure in the packing house for one day appeared to have shown a very slight disadvantage, although this experiment is not sufficiently complete to warrant a definite conclusion. On the whole, there was a marked diminution in the loss when the pineapples were fumigated with formaldehyde. In regard to the fruit from dark soils as compared with that from red soils, the results thus far suggest that the fruits from the lower dark fields may be more subject to decay than those from the upper red fields. With fruit placed between the decks the loss was much heavier than on the main deck, running up to the proportion of 42.8 per cent in the case of unfumigated stock.

Shipments of avocados were also made at the same time, the fruit having been submitted to cold storage previous to shipment. The results indicate that it is possible to ship this fruit to direct markets without greater loss than is experienced in average fruit shipments. Directions are given with regard to picking, grading, wrapping, packing, crating, and shipping avocados. The degree of temperature which is best for the preservation of avocados in transit has not been determined, although experiments made at the station show that prolonged storage in temperatures such as are used for peaches, grapes, plums, etc., result in the blackening of the interior of the avocado. It is recommended that the mercury should not fall below 40° F. Shipping on deck without refrigeration has not proved successful.

Tabulated results are given of the trial shipments of papaias. The fruit of the long type is considered better for shipping than the round, since this shaped fruit can be packed more securely, thus preventing the motion of the fruit within the crate. At the present stage of the investigation it is suggested that fruit which is beginning to show indications of ripening be shipped to such ports as San Francisco or others which are reached by direct journey. Fruit which is gathered green does not acquire as fine a color as that which has started to ripen on the tree, though it will become ripe and marketable if fully grown. Brief suggestions are given for the preparation, refrigeration, style of crates, and shipment of papaias.

The author discusses the source of supply and market possibilities of bananas, and is of the opinion that all of the markets west of the Great Plains might be supplied with bananas grown in Hawaii. Efforts are being made to introduce the Hawaiian cooking bananas, which are said to take the place of fresh vegetables and cooking fruits.

No shipments have thus far been made with mangoes, although they have been found to keep much longer than avocados under refrigeration without deterioration in quality. It is believed that the mango industry will become important in Hawaii when the demand for this fruit increases, provided some immediate and stringent action on the part of the Government is taken in the destruction of the mango weevil (*Cryptorhynchus mangiferæ*), which at the present time threatens the industry.

In conclusion, the author discusses the present system of marketing by commission and consignment, which he considers entirely unsatisfactory.

Seedless apples (*Wis. Hort. Soc. Bul. 11, pp. 11, figs. 4*).—In this bulletin the opinions of several well-known horticulturists are given with respect to the relative value of the Spencer seedless apple.

In general it appears that while the Spencer apple is usually seedless, "an occasional seed being found near the calyx, and sometimes just under the skin," it is by no means coreless and is inclined to be wormy. Several reports from nurserymen are given with reference to the cost of good trees of standard apples in Wisconsin, from which it appears that 6 good standard trees can be bought for $2, the price of 1 Spencer seedless apple. The latter variety is considered only a novelty and worth only a fraction of this price.

Fig culture, E. STEARNS (*Estac. Agr. Expt. Ciudad Juárez, Chihuahua, Bol. 8, pp. 33, pls. 8*).—This is a popular treatise on fig culture, including notes on the history, climatic and soil conditions, cultural operations, harvesting, curing, packing, shipping, and marketing, together with an account of the culture of Smyrna figs, the introduction of the Capri or wild fig, and the naturalization of the *Blastophaga grossorum*, by means of which the Smyrna fig is caprified or fertilized. The subject-matter is based principally on data secured from fig culture in California and furnished largely by G. C. Roeding, whose publication on the Smyrna fig has been noted (E. S. R., 15, p. 366).

Fall delivery of fruit trees (*Oklahoma Sta. Rpt. 1907, pp. 19–21*).—Popular directions are given for receiving and protecting fall-delivered fruit trees, together with instructions for transplanting. It is advised that the trees be unpacked and inspected before being accepted.

The factors which determine the quality of tea, H. H. MANN (*Indian Tea Assoc.* [*Pamphlet*] *4, 1907, pp. 29*).—This report is based on an address delivered by the author at several planters' meetings in India, the data being taken for the most part from various publications by the author on tea culture and manufacture (E. S. R., 19, p. 238).

The various factors said to affect the culture of tea are briefly considered, including the effect of elevation and latitude, regularity and sufficiency of rainfall, variety of plant, special character of soil and manuring, kind of pruning, method of plucking, and system of manufacture, including withering, rolling, fermentation, and firing.

Tea planting companies (*Economist, 65* (*1907*), *No. 3330, pp. 1060, 1061*).—General statements and tabular statistics are given with reference to the results of 18 tea planting companies in India and Ceylon. With all but 2 companies the earnings for 1906 increased over those of 1905. According to figures provided by the Board of Trade returns, with regard to the statistics of British foreign trade for 1906, it appears that the amount of tea taken from China had decreased by 13,352,087 lbs. in the past 2 years, while the increase in imports of tea from India during the same period amounted to 13,452,235 lbs. From this it appears that Indian producers are gaining what the Chinese are losing.

Bush fruits, W. T. MACOUN (*Canada Cent. Expt. Farm Bul. 56, pp. 67, pls. 4, figs. 7*).—This is a general and popular bulletin dealing with the history, cultivation, varieties, and insects attacking the currant, gooseberry, raspberry, and blackberry. The work is based principally upon variety tests and cultural experiments conducted at the Central Experimental Farm during the past 20 years. All of the varieties tested at the station are listed and descriptions are given of the most promising varieties, including 45 varieties of currants, gooseberries, and raspberries originated by W. Saunders. Lists are also given of varieties recommended for planting, together with considerable data with regard to yields of currants and raspberries secured in the station trials.

Descriptions are given of the insects injurious to fruits, with remedies for the same by J. Fletcher. The work concludes with a historical sketch of the work of W. Saunders in improving the currant, gooseberry, and raspberry.

A previous bulletin on raspberries, reporting the station work up to 1895, has already been noted (E. S. R., 7, p. 403).

Experimental work in the vineyard of the [Peru] National School of Agriculture, F. CHABERT (*Bol. Min. Fomento* [*Peru*], *4* (*1906*), *No. 12, pp. 1–8, map 1*).—An outline is given of the various lines of work either under way or to be conducted by the author and Señor Dubosc in the vineyard of the National School of Agriculture. Important investigations now in progress are the determination of the durability of different varieties of wood used for vineyard posts, experiments with different systems of pruning, and variety tests. Irrigation and fertilizer experiments are to be instituted, and an attempt is being made to arrive at some means of producing thoroughly matured wood on the vines.

India's poppy and opium, W. H. Michael (*Daily and Consular Trade Rpts.* [*U. S.*], *1907, No. 2932, pp. 1-3*).—A brief account of poppy culture and the preparation of opium for market in India. Deep plowing is said to be practiced for the poppy, whereas with other crops grown in India shallow plowing is the rule.

In the operation of sowing, the poppy seed is mixed with sand so that it will not be sown too thick, and one-third of the required amount is then scattered over the field, after which the field is watered. When the soil is sufficiently dry the land is again plowed more shallow than at first, harrowed, and another third of the seed sown. Similar treatment follows the second sowing, when the field is sown for the third time. Three pounds of poppy seed are required for 1 beegah or about ⅝ acre of land. The entire crop is purchased by the Government with the exception of small amounts, which are reserved for the use of the farmers.

The value of the opium export from India in 1906 is given as $30,640,080, of which $24,032,260 went to treaty ports in China. The Government pays $2.90 per seer (a little over 2 lbs.) for liquid opium, 8 to 10 cts. per seer for the dry cake, 4 to 6 cts. per bundle for the dry stalks, and 49 cts. per seer for seed in heads. Practically the entire crop is raised on small farms.

Lemon grass in Ceylon, H. Wright and M. K. Bamber (*Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon 3* (*1906*), *No. 19, pp. 263-270b, dgm. 1*).—The cultivation of lemon grass in preference to that of citronella is said to be increasing in many parts of Ceylon on account of the high price at present paid for the pure oil of the former. This circular contains an account of experiments with lemon grass conducted at the Peradeniya experiment station since 1901, including a botanic description, the climatic and soil conditions, cultivation and distillation at the station, together with several reports on the physical and chemical properties of the oil obtained. A diagram is given of a citronella oil still.

In the past the cultivation of lemon grass has been confined to the southern parts of Ceylon, in places near sea level and supplied with a rainfall of 100 in. or more, and an average temperature of 80° F., but in the present experiments the grass has been successfully cultivated at an elevation of 1,600 ft., where the annual rainfall is about 82 in. and the mean annual temperature about 75.5° F.

Four seasons in the garden, E. E. Rexford (*Philadelphia and London, 1907, pp. 307, pls. 27*).—Popular directions are given for the making and care of lawns and of gardens of various kinds for different seasons of the year, including the winter window-garden, and greenhouse cultivation of flowers. Attention is also directed to the culture and care of bulbs, palms, and decorative plants, together with an account of the organization of a village improvement society and suggestions for forming such societies. The text is well illustrated.

A case of degeneration of tuberous plants, N. Bernard (*Bul. Soc. Linn. Normandie, 5. ser., 9* (*1905*), *pp. 251, 252*).—A brief note is given on the behavior of plants of 2 species of coleus (*C. coppini* and *C. daso*), which were sent from Lake Tchad, in the interior of Africa, to the botanical garden at Caen. The tubers of both species were grown in a temperate greenhouse and in the open ground, but in both cases failed to reproduce tubers. The plant grown in the open ground remained small and insignificant, while the plant grown in the greenhouse grew well and produced abundant roots. The author is of the opinion that this degeneration may be attributed more to the change of environment than to the change of climate.

The hybridization and propagation of orchids from seed, F. Ledien (*Möller's Deut. Gärt. Ztg., 22* (*1907*), *Nos. 18, pp. 206-216; 19, pp. 217-228; 20, pp.*

230–232, figs. 34).—This is an illustrated series of articles containing numerous observations on hybridizing, crossing, and propagating tropical orchids. The author states that it is a matter of constant occurrence that certain genera and species are found to be capable of greatly affecting, altering, or completely suppressing in their progeny the features of the species and genera with which they are crossed. Numerous examples of this occurrence are given.

The bagging of flowers (*Jardin, 21* (*1907*), *No. 486, p. 145*).—This is a brief note in regard to the recent experiment of M. Vilaire, of the Rouen botanical garden, on the bagging of lilac blooms. Several blooms scarcely in bud were bagged on March 24 last and came into full bloom on April 26, whereas the check blooms at the latter date showed only buds. These experiments are to be continued with other varieties of flowers.

A peony check-list, J. E. Coit (*Ithaca, N. Y.: N. Y. State Col. Agr., 1907, pp. 232, figs. 2*).—The author is conducting an extensive peony investigation for the purpose of remedying the existing confusion regarding the names of varieties, and of offering simple but complete and accurate descriptions of the same.

The present list comprises the information which has been gathered in connection with this work from books, periodicals, manuscripts, etc., and includes the leading varieties of peonies of which authentic descriptions can be found in horticultural literature. The varieties which have been found illustrated, together with the place thereof, and those varieties which may be found in the Cornell plats are all indicated. The list comprises 2,706 varieties and is introduced with a description of the Cornell system of alphabetical classification. In conclusion some general lists of varieties recommended are given.

Roses proof against mildew in Australia (*Gard. Chron., 3. ser., 41* (*1907*), *No. 1065, p. 333*).—In this note a list taken from the journal of horticulture of Australia is given of a large number of roses, which are said to be proof against mildew in that country.

FORESTRY.

Notes on the radial increment of tree trunks, O. Lignier (*Bul. Soc. Linn. Normandie, 5. ser., 9* (*1905*), *pp. 181–224*).—The author made studies of cross-sections of several species of trees belonging to the botanical collection at Caen, for the purpose of determining whether a satisfactory formula could be derived for computing the age of trees with the aid of the circumference. The results of these studies are discussed in detail, and the data obtained from each species with reference to its yearly-growth increment are presented in tabular form.

The more important general conclusions derived from this work are, in substance, as follows: The life of a tree may be divided into 2 periods, which vary according to the species. During the first period, or period of acceleration, the thickness of the annual rings increases from year to year. During the second period, or period of abatement, the thickness of the annual rings diminishes progressively, although in this latter period there is an intermediate phase in which the difference is hardly perceptible, a second phase in which the thickness decreases consistently, and a third phase in which the change again becomes slow. The age of the tree can not be correctly obtained by dividing the radius or diameter of the tree by an average annual growth measurement, but the growth rings must be actually counted. Where an attempt is made to estimate the age from the circumference, the measurement should be made at a distance of about 1.3 meters from the ground.

In the case of Taxus, it was noted that certain annual layers did not extend completely around the tree. With the same species it was found that as the trunk grew numerous small twigs were imprisoned. Where these twigs were alive they were surrounded by the wood, and where they were dead they were more closely united with the trunk.

Determination of the germination of seeds of forest trees, G. Schotte (*Skogsvårdsför. Tidskr., 5 (1907), No. 4–5, pp. 141–155*).—An account is given of experiments with the Rodewald-Cieslar germination apparatus and other methods of determining the germination of seeds of forest trees, with accounts of the work in this line done by other foresters. The best method for determining the germination of these seeds, in the author's opinion, is the one that will cause all viable normal seeds in the sample to germinate in the shortest possible time.—F. W. WOLL.

Annual progress report of forest administration in the western and eastern circles of the United Provinces for the forest year 1905–6, L. Mercer and H. Jackson (*Ann. Rpt. Forest Admin. West. and East. Circles [India], 1905–6, pp. 148*).—In this report the usual statements are given in regard to the constitution of State forests, the management, protection, sylviculture, exploitation, financial results, and administration for each of these regions, with tabulated annual statements in regard to the various phases of the work, including forest areas, surveys, receipts, disbursements, etc.

On fire stations in the Norrland forests, O. H. Humble (*Skogsvårdsför. Tidskr., 5 (1907), No. 4–5, pp. 158–171*).—The author recommends the establishment of a system of fire towers in forest districts for the ready discovery and extinction of forest fires. These may be located at points some 30 miles apart and connected with one another by means of a telephone system. The initial expenses are estimated for Jämtland County, Sweden, as follows: 2,000 kronor ($536) per tower, with 19 miles telephone connections, exclusive of poles, or 2,500 kronor ($670) with 33 miles telephone connections. The annual expenses connected with the maintenance of a system of 20 stations, including the pay of a watchman at each tower for 100 days would amount to 10,000 kronor ($2,680). This number of stations would serve to protect 2,873,513 hectares of forest at an expense of 35 oere (9.4 cts.) per 100 hectares per year.—F. W. WOLL.

The main features of the Norrland forest management, P. O. Welander (*Skogsvårdsför. Tidskr., 5 (1907), No. 3, pp. 139–149*).—F. W. WOLL.

Instructions for examinations. Agricultural settlement. (Act of June 11, 1906) (*U. S. Dept. Agr., Forest Serv. [Pamphlet], 1907, July 1, pp. 12*).—The act of June 11, 1906, provides for the entry of agricultural lands in forest reserves. This pamphlet gives directions as to the examination by officials of the Forest Service of lands so entered, and the keeping of records relating thereto.

Practical advice for making plantations in Algeria, E. Le Men (*Bul. Off. Gouvt. Gén. Algérie, 1907, Sup. 8, pp. 91–115*).—This pamphlet was prepared for the encouragement of various forms of tree plantings in Algeria, and includes popular directions for the selection of soil, and planting, cultivating, pruning, grafting of trees, including their use along avenues, highways, and irrigation canals, in the creation of wooded areas, and olive plantations.

On the loss in weight of drying logs and firewood, W. Ekman (*Skogsvårdsför. Tidskr., 5 (1907), No. 4–5, pp. 129–140*).—Determinations were made of the percentage decrease in weight of spruce, pine, and birch logs during the first 3 years after cutting both with the bark on and half or entirely barked. The losses ranged from 10 per cent (unbarked pine) to 45 per cent (barked spruce) for trees cut before June 1. The same percentage losses were obtained about July 1, whether the trees were cut early in the year or by June 1. Losses in the weight of fuel wood are also reported, as well as for whole trees with their branches on.—F. W. WOLL.

Production of lumber, lath, and shingles, by States and species, 1906, 1905, and 1904 (*Bur. of the Census [U. S.]; U. S. Dept. Agr., Forest Serv., 1907, July 19, folio*).—This folder, prepared jointly by the Bureau of the Census of the Department of Commerce and Labor and the Forest Service of the Department of Agriculture, contains tabulated returns from 21,077 mills in 1906, 11,666 mills in 1905, and 18,277 mills in 1904.

The use of carbolic acid emulsion in the impregnation of beech ties, R. LORENZ (*Centbl. Gesam. Forstw., 33 (1907), No. 4, pp. 137–141*).—The author has made experiments in the preservation of wood with different solutions, and is of the opinion that carbolic acid emulsion is not only less costly than tar oil but more effective. His experiments are described in detail. The cost of preserving a beech sleeper of 1 cubic meter with pure carbolic acid is said to be from about 12 to 16 cts., depending on the percentage of emulsion absorbed, and when introduced under a pressure of from 8 to 10 atmospheres the emulsion is said to occupy from 25 to 40 per cent of the volume of air-dried ties. When used with larger timber this emulsion is said to penetrate the wood equally as well as water or various soluble salt solutions.

Jamaica timbers, W. HARRIS (*Agr. News [Barbados], 6 (1907), No. 127, p. 71*).—In an article to the *Jamaica Daily Telegraph* the author suggests the use of local timber supplies in the rebuilding of Kingston, and gives a long list of native timbers suitable for house work, shingles, wharf piles, etc.

The staff-tree (Celastrus scandens) as a former food supply of starving Indians, F. T. DILLINGHAM (*Amer. Nat., 41 (1907), No. 486, pp. 391–393*).—Reference is made to the use of the staff-tree by some tribes of North American Indians in times of starvation. As a result of recent tests of both the bark and wood, conducted at the Bussey Institution of Harvard University, it appears that unlike the bark of most deciduous trees that of the staff-tree contains an abundance of a carbohydrate, known as mannan, to the presence of which is attributed a part at least of its physiological value.

The longleaf pine in virgin forest, G. F. SCHWARZ (*New York and London, 1907, pp. 135, figs. 23, dgms. 2, map 1*).—This book is intended as a contribution to the life history of the longleaf pine (*Pinus palustris*), with the view of presenting some of the most important silvical facts regarding this tree. The work is designed primarily for foresters, forest students, and owners and managers of southern pine timber lands.

The important phases under consideration are the character of virgin longleaf pine forests, natural rotation or evolution in the forest, tolerance, fires, the soil cover, injury to seedlings caused by hogs, rate of growth in virgin forest, and forest management. The work concludes with a chapter on the æsthetics of forestry. The text is illustrated with numerous figures and a map showing the general distribution of the longleaf pine.

Northern limit for spruce, A. W. GRANIT (*Skogsvårdsför, Tidskr., 5 (1907), No. 4–5, pp. 217, 218, fig. 1*).—A photographic reproduction and note on a spruce tree, which the author found growing in the Pasvig Valley near Klister Lake, South Varanger, in Russian Lappmark, at 69° 32′ 38″, and believes to be the northernmost spruce in the world. The tree was about 45 ft. high and 10 to 12 in. in diameter, 5 ft. from the ground.—F. W. WOLL.

Investigations on the production of caoutchouc from Manihot glaziovii, A. ZIMMERMAN (*Pflanzer, 3 (1907), No. 4, pp. 49–61*).—Tabular results are given of the author's rubber-tapping experiments with *Manihot glaziovii* in German East Africa, in which various systems of tapping were used, including the "Querring" method, perpendicular stripping, single incisions over large area, and the spiral and V-shape cut methods. The 3 former methods are the most successful thus far. At the end of 1 year's tapping from 9 trees less than

4 years of age, an average of 218 gm. of dry caoutchouc was produced per tree, the stems and larger branches both being tapped. One of these trees yielded 481 gm. and another 440 gm.

With regrad to the spiral method of tapping, the average yield of caoutchouc per single tapping was very small, ranging from 1.2 to 1.52 gm. of dry caoutchouc. The author is of the opinion that it will not compare favorably, even on older trees, with the 3 former methods. The V-shape method is considered worthy of further trial.

The greatest average yield per single tapping was secured with the single incision method over large surface, in which the average yield per tapping was 4.33 gm. of dry caoutchouc.

On some rubber plants in South Madagascar, J. Costantin and H. Poisson (*Compt. Rend. Acad. Sci.* [*Paris*], *144* (*1907*), *No. 19, pp. 1053-1055*).—In a recent tour through South Madagascar, M. Geay collected several species of caoutchouc, which are exploited to considerable extent by the natives. From 2 of these, locally known as Kokomba and Kidroa, the rubber is said to be extracted from the roots, which are gathered and exposed to the sun in order to create a rapid coagulation of the latex, after which they are beaten with a piece of hard wood. The separated bark is then pounded to a pulp and the mass boiled with water, in order to eliminate the greater portion of the free bark. The drying and boiling is repeated once or twice, after which the rubber is made up into regular commercial balls.

The authors describe these plants as new species of Mascarenhasia, *M. geayi* and *M. kidroa*, respectively. Two species of Landolphia, discovered at the same time, have been named *L. mamolava* and *L. mamavo*, and are also described.

Rubber from a tuber at last (*India Rubber World, 36* (*1907*), *No. 4, p. 300, fig. 1*).—A brief account is given of a tuberous rubber plant found in Portuguese West Africa, and reported by C. E. de Mello Geraldes, of the agronomical institute at Lisbon. This plant is locally known as "ekanda" and "marianga" and has been ascribed by J. Henriques to the natural order Asclepiadaceæ. It is said to flourish particularly in the sandy, treeless plateaus between the Kwanza and Zambesi rivers, and is described in part as a stemless biennial plant with a fleshy yellow tuberous root, sometimes turnip-shaped, but usually resembling a flattened sphere, the entire substance of which is permeated with lactiferous ducts.

Rubber has been obtained from the "ekanda" tubers by various crude experimental processes, chiefly by slicing them and applying pressure. Tubers 2 years old are referred to as attaining a diameter of 5½ in. and a weight of 1⅛ lbs. A rubber yield of ½ per cent of the total weight resulted from the crude processes.

DISEASES OF PLANTS.

The injurious effect of high germination temperatures upon the subsequent development of cereals, O. Appel and G. Gassner (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 5-7, fig. 1*).—During the spring and summer of 1906 the authors noticed in the summer grainfields about Dahlem a peculiar diseased condition, which examination of material showed was not due either to fungi or insects. The plants had lost their usual green color and the lower leaves were dead. It was suggested that the high temperature following the seeding might have been the cause of the injury, and pot experiments were undertaken with wheat, barley, and oats, one series of which was kept at 20 to 25° C. and the other from 5 to 7° during the period of germination.

After 3 weeks' subjection to the above temperatures the plants at the higher temperature showed the characteristic appearance noted above. Soil and fertilizer studies showed that these agents did not produce the trouble described and that the injury must have been caused by the high temperature at and following the period of germination.

As a practical means for preventing injury due to this cause the authors recommend the late seeding of winter grains and the early seeding of spring cereals.

The alteration of forage by parasitic plants, A. PORCHEREL (*Jour. Méd. Vét. et Zootech., 58 (1907), March, pp. 154–166, figs. 6; June, pp. 346–359*).—A résumé is given of literature relating to the changes induced by rusts, smuts, ergots, molds, etc., on various forage plants, and the effect produced on animals by feeding the infected forage.

Some investigations on the loose smut of cereals, O. APPEL and G. GASSNER (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 9–12, fig 1*).—The relation between the germination of cereals and the infection by smut is discussed. The authors claim that the more rapidly the cereal germinates the less subject it is to attacks of smut through seedling infection. The partial resistance of certain varieties of cereals to smut is due, in the authors' opinion, to the fact that the seed germinates and develops the seedling stage more quickly than others that are quite susceptible to disease.

A smut of tall oat grass, O. APPEL and G. GASSNER (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 12, 13*).—The authors describe *Ustilago dura* n. sp. as occurring on tall oat grass. The fungus resembles *U. perennans*, but differs from that species in important characters.

Changes in the head of square head wheat due to smut, O. APPEL (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, p. 12, fig. 1*).—On account of the reported effect of smut on square head wheat the author conducted some experiments in which alternate plats were seeded with infected and clean seed. The resulting crop showed profound changes in the character of the wheat heads, the normal square head being changed into an elongated, narrow, loosely spiked head. Where there was no infection the normal type of heads prevailed. The change is attributed to the smut, and it is said that frost or other injury will produce similar modifications.

Treatment of wheat for loose and stinking smuts (*Oklahoma Sta. Rpt. 1907, pp. 16–19*).—Directions are given for the treatment of wheat for the prevention of loose and stinking smuts, the information being drawn largely from Farmers' Bulletins of this Department (E. S. R., 10, p. 154; 17, p. 1078).

Notes on Fusarium, O. APPEL (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 31–33, fig. 1*).—The author describes the injury to various species of Leguminosæ by attacks of Fusarium, also a disease of cereals, known as the foot disease, which is attributed to a species of Fusarium, and the action of these fungi in destroying cellulose.

Notes on clover canker, R. ADERHOLD (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 21–24, figs. 2*).—The clover fields of parts of Germany are said to be frequently attacked by a disease which is variously referred to as canker or winterkilling, etc., but an examination of the plants showed that it was due mainly to *Sclerotinia trifoliorum*. The effect of the fungus on the host plant is described and notes given on the life history of the parasite. Experiments have been inaugurated to test the susceptibilty of various varieties of red, alsike, white, and crimson clover, and alfalfa to this fungus.

Clover sickness (*Jour. Bd. Agr. [London], 14 (1907), No. 4, pp. 223–227, figs. 2*).—Clover sickness is said to be due largely to attacks of nematodes (*Tylenchus devastatrix*) or the fungus *Sclerotinia trifoliorum*. Evidence is offered to show that the nematodes are a primary cause of clover sickness, and that in addition to attacking the clover, potatoes, strawberries, onions, and oats are subject to infestation.

Where crops show signs of disease, applications of sulphate of potash are recommended, and where practicable the sterilization of the soil by the use of gas lime is advised. The removal and burning of infested material will greatly aid in preventing the spread of the disease.

Cotton anthracnose and cotton rust, A. C. LEWIS (*Ga. Bd. Ent. Bul. 24, pp. 49–71, figs. 8*).—A description is given of the anthracnose of cotton caused by *Colletotrichum gossypii*, and the relation of certain insects to the disease is discussed. It is believed by many that a number of insects, such as the green soldier bug, the cotton leaf bug, and others, by puncturing the bolls cause the disease, but in the author's opinion there is no relation between the insect puncture and the anthracnose, aside from the possibility of spreading the disease by insects visiting from boll to boll.

Among remedies suggested for the prevention of anthracnose the author discusses resistant plants, resistant varieties, the rotation of crops, and treatment of seed before planting.

The red rust, black rust, angular leaf spot, etc., are briefly discussed.

The root rot of sugar beets, W. BUSSE, L. PETERS, and F. C. VON FABER (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 15–18*).—As a result of experiments the authors recognize three causes of root rot of sugar beets, namely, *Pythium debaryanum*, *Phoma betæ*, and *Aphanomyces lævis*, and they think it very improbable that *Myxomonas betæ* is the cause.

Experiments were conducted to prevent root rot by treating the seed with solutions of calcium carbonate and Bordeaux mixture and by soil treatment with slaked and quick lime The results obtained with the carbonate of lime do not warrant its further trial. Bordeaux mixture gave favorable results, and the experiments in soil treatment are to be continued.

A pustule scab of beets, W. BUSSE and F. C. VON FABER (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 18–20, fig. 1*).—A brief description is given of a form of scab occurring on sugar beets in northern and central Germany, the cause of which is said to be *Bacterium scabiegenum* n. sp. A previous report of this disease has been noted (E. S. R., 18, p. 948).

Black rot of cabbages and turnips (*Jour. Bd. Agr. [London], 14 (1907), No. 4, pp. 228, 229, fig. 1*).—An account is given of the black rot of cabbages and turnips due to *Pseudomonas campestris*, and it is stated that in England rape appears to be most susceptible to the disease.

In an extensive trial plat with various kinds of cabbage, Brussels sprouts, etc., those strains which are related to rape were first attacked, while those without this relationship were the last to succumb.

Attention is called to the investigations carried on at the New York State Station (E. S. R., 16, p. 480), which showed that the disease might be carried through infected seeds, and as a precautionary measure it is recommended that all cabbage seeds be disinfected by soaking them for 15 minutes in a solution consisting of 1 part of corrosive sublimate to 1,000 parts of water, or 1 lb. of formalin to 30 gal. of water.

Crown gall (*Oklahoma Sta. Rpt. 1907, pp. 24–26*).—A popular account of the crown gall, which attacks apples, pears, peaches, apricots, and other fruit trees. A warning is given against the planting of infested stock.

Cedar apples (Gymnosporangium macropus), F. D. HEALD (*Science, n. ser., 26 (1907), No. 659, pp. 219, 220*).—During the past few years cedar rust has increased in abundance and severity in Nebraska and adjacent States, threatening the life of cedars in many places where they are used as wind-breaks about orchards. In many localities the cedars are considered very valuable and assistance has been asked to save them from the destructive effect of this fungus. As a result observations have been made on the life history of the rust, and spraying experiments are in progress.

In 1906 it appears that the first cluster-cups on the apple matured about the first of July, but at this date only a few were open and these were mostly on fruit where two or more apples were in contact. A few days later young cedar apples as large as radish seeds were abundant on the cedars. Observations made at other points showed the almost simultaneous occurrence of the fungus on the apple and the cedar. Small cedar trees were inclosed in glass houses so ventilated as to prevent infection from the outside, but cedar apples developed upon them early in July.

Concerning these observations the author offers two explanations, either that the fungus is perennial or the æcidial spores of one season produce the cedar apples which appear in June of the next year and reach their maturity in the autumn. There appears to be some evidence of the perennial character of the mycelium, but the second explanation is at present believed more probable. If this is true, the cedar is probably infected in summer and autumn, but no evidence of the resulting cedar apples can be noted until the next season's growth. It would then require two years for a cedar apple to develop. Further observations are being carried on to substantiate this view.

The relationship of Phyllosticta solitaria to the fruit blotch of apples, J. L. SHELDON (*Science, n. ser., 26 (1907), No. 658, pp. 183-185*).—The fruit blotch of apples has been previously referred to an undetermined species of Phyllosticta (E. S. R., 13, p. 1059; 18, p. 1062), and the author reports having observed the fungus on the wild crab apple as well as on cultivated apples. A study of the material showed that the parasite in both cases was the same, and it was determined that the blotch disease of apples is caused by *P. solitaria*, a fungus occurring either on the leaves, fruits, or branches of the wild crab and cultivated apple.

Control of bitter rot of apples, J. C. BLAIR (*Illinois Sta. Circ. 112, pp. 13*).—This circular consists of a summary of results of the work carried on at the station, the details of which are to be published in a forthcoming bulletin. The principal results obtained indicate that the disease can be successfully controlled by the application of standard Bordeaux mixture, the sprayings to be made so that the fruit will be well covered with the fungicide. Spraying the dormant trees with copper sulphate solutions or other strong washes is said to be ineffective in controlling the bitter rot. The application of salt on the ground about trees was found to be without any value.

Experiments with black spot of apple, D. MCALPINE (*Jour. Dept. Agr. Victoria, 5 (1907), No. 6, pp. 362, 363*).—On account of the claims made that a number of proprietary sheep dips have important fungicidal value, the author carried on in 1905-6 and 1906-7 a series of spraying experiments to compare their efficiency with Bordeaux mixture and soda Bordeaux mixture in controlling black spot of apples. From the experiments it is conclusively shown that sheep dips, phenyl, and similar preparations are not to be compared with Bordeaux mixture or copper soda mixture as a treatment for black spot.

Some new parasites of cacao, L. LUTZ (*Bul. Soc. Bot. France, 53 (1906), pp. XLVIII-LII, figs. 2*).—Descriptions are given of 3 parasites that have been recently recognized as occurring on the pods and seeds of cacao. The species described are *Macrosporium verrucosum* n. sp., *Sterigmatocystis luteo-nigra* n. sp., and *Fusarium theobromæ* n. sp.

Concerning thrombosis of currants and gooseberries, R. ADERHOLD (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 26, 27*).—A brief description is given of a disease of currants and gooseberries in which the water conductive tissues are plugged by growths of the mycelium of a species of Verticillium.

The American gooseberry mildew attacking red currants, E. S. Salmon (*Gard. Chron., 3. ser., 42 (1907), No. 1072, p. 26*).—While investigating an outbreak of American gooseberry mildew (*Sphærotheca mors-uvæ*), the author found that the fungus had spread to red currant bushes which were growing intermixed with gooseberry bushes. This fact seems to show that the fungus is capable of directly attacking and living on the red currant and does not require time to accustom itself to this host.

In addition the author mentions having observed the European gooseberry mildew (*Microsphæra grossulariæ*) occurring on red currant bushes. In this case the mildew was not confined to the leaves, as is usually the case, but occurred also upon the berries.

Notes on some diseases of the grape, L. Ravaz (*Bul. Mens. Off. Renseig. Agr. [Paris], 6 (1907), No. 7, pp. 837, 838*).—The author reports failure to discover the mycelium of *Uncinula americana* on the young shoots or on the bud scales of the grape, where it is claimed the fungus passes the winter. He has found it quite regularly within the dormant buds about the axis and among the developing grapes within the buds. If the fungus normally winters in this way, the failure to prevent the appearance of powdery mildew by the use of strong washes on the dormant vine is explained.

Court-noué, a destructive disease in central France, Italy, and Spain, the cause of which has been attributed to various species of bacteria, fungi, etc., is due, according to the author, to the action of late frosts upon the young shoots.

Another disease of grapes, to which the name apoplexy is given, is caused by *Polyporus igniarius* and not by accidental and meteorological conditions.

The injury of grape leaves through the application of fungicides, F. Muth (*Mitt. Deut. Weinbau Ver., 1 (1906), No. 1, pp. 9–18; abs. in Bot. Centbl., 105 (1907), No. 28, pp. 26, 27*).—Attention is called to the injury of grape leaves due to the use of heavy applications of Bordeaux mixture for the prevention of attacks of downy mildew. Often the young leaves are entirely destroyed and the older ones covered with small brown spots. The Reissling grapes appear especially subject to Bordeaux mixture injury, while the American varieties seem more resistant to weather conditions and to the injurious effect of the fungicide than most European varieties. For the tender sorts spraying with 1 per cent Bordeaux mixture is recommended.

The leaves and fruits of the apple are said to be subject to similar injury.

Cocoanut bud rot, W. T. Horne (*Bol. Ofic. Sec. Agr. Cuba, 3 (1907), No. 1, pp 1–5*).—An account is given of investigations by the author on the bud rot of cocoanut trees in different parts of Cuba. This disease has become quite destructive in certain groves, but it is believed that destroying the affected trees by burning, if promptly done, will hold it in check. The author outlines a series of investigations on this disease which he plans to take up.

Leaf blight of the plane tree, W. A. Murrill (*Jour. N. Y. Bot. Gard., 8 (1907), No. 91, pp. 157–161, figs. 2*).—An account is given of a serious fungus disease which during the past season has caused the leaves and young twigs of the plane or sycamore tree to change color and die as though scorched by fire. This disease was quite conspicuous throughout the eastern part of the United States during the past season, and is attributed to the fungus *Glœosporium nervisequum*. The mycelium of the fungus lives within the leaves and twigs, the fruiting portions appearing in brown patches on the twigs or leaves that have been killed. Both the American and Old World species of sycamore are subject to attack, but the effects of the fungus are ordinarily not lasting, except in the case of trees already weakened by disease or starvation.

No treatment for the disease is suggested, as on account of the large size of the trees and the fact that the fungus is an internal parasite in the leaves and twigs, spraying would not be possible.

A blight disease of young conifers, P. Spaulding (*Science, n. ser., 26 (1907), No. 659, pp. 220, 221*).—During the past spring a serious outbreak of blight was noticed in a large conifer nursery in Nebraska on the needles of 2-year-old seedlings of *Pinus ponderosa* and *P. divaricata*. The damage was very considerable, several hundred thousand trees being affected.

The disease is characterized by a gradual dying back of the needles from the tip to the base. From specimens of diseased trees placed in moist chambers spores were obtained of a species of Pestalozzia. Cultures were made from these and successful inoculations made on healthy seedlings. The various species of Pestalozzia have been known as parasites of conifers in Europe, but while the fungus has been found in this country, its presence as an active parasite seems to have been overlooked.

For preventing the spread of this disease throughout the nursery the author recommends the removal and burning of diseased trees, accompanied by thorough spraying of the remainder with Bordeaux mixture containing some adhesive substance.

Some smut diseases of garden plants, G. Korff (*Prakt. Bl. Pflanzenbau u. Schutz, 5 (1907), No. 7, pp. 79–82, fig. 1*).—Descriptions are given of the smut of violets, due to *Urocystis violæ*, and onion smut (*U. cepulæ*), and the occurrence noted of *U. gladioli* on gladiolus, *U. anemones* on species of aconite and anemone, *U. filipendulæ* on spiræa, and *Ustilago scorzoneræ* on black salsify, *U. violacea* on pinks, and *U. tulipæ* on tulips.

The leaf-tip blight of Dracæna fragrans, J. L. Sheldon (*Jour. Mycol., 13 (1907), No. 90, pp. 138–140*).—The author reports studies on the diseased leaves of greenhouse specimens of *Dracæna fragrans*, in which the lower leaves were entirely dead and the middle ones dead at their tips. Small black specks were scattered throughout the dead portions of the leaves, and a microscopical examination showed that they had probably been killed by a species of Glœosporium.

The author found that a similar trouble had been described in a report of the New Jersey Station (E. S. R., 6, p. 823) in which the fungus was attributed to Glœosporium. A study of the material mentioned above revealed some doubt as to the specific relationship of the parasite, but as it corresponds more nearly to the genus Physalospora than any other, it is placed in that genus for the present, and the name *Physalospora dracæna* n. sp. proposed for it.

A bacterial disease of cultivated stock, F. C. von Faber (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 24, 25*).—The author notes the occurrence of *Pseudomonas campestris* upon cultivated stock.

Protection against plant diseases and insects (*Oklahoma Sta. Rpt. 1907, pp. 26–31*).—Formulas are given for the preparation of Bordeaux mixture, Paris green, and Bordeaux mixture to which Paris green is added, together with directions for their application.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Selection and crossbreeding in relation to the inheritance of coat pigments and coat patterns in rats and guinea pigs, H. MacCurdy and W. E. Castle (*Carnegie Inst., Washington Pub. 70, pp. 50, pls. 2, figs. 5*).—The experiments reported in this paper were undertaken to obtain evidence of value in determining whether evolution and the formation of species are accomplished by the natural selection of minute variations or by mutation. The experimental animals were rats and guinea pigs and were crossed according to various plans so as to make easy the determination of the laws which prevailed in the inheritance of color patterns in their coats.

It was found that the inheritance of color patterns took place, in most cases, according to Mendelian requirements, but that inheritance is both alternative and blending. Since it is impossible to distinguish between continuous and discontinuous variations, and between blending and alternative inheritance, it seems unwise to attribute evolutionary processes to one sort of evolution only.

The cause of partial and total albinism, J. H. W. T. Reimers (*Cultura, 19 (1907), No. 224, pp. 267–274*).—The literature relating to this subject is discussed in connection with bibliographical notes. The author reaches the conclusion that albinism in domestic animals is a recessive character in the Mendelian sense.

Experiments in the destruction of rats on board ship by means of liquid sulphurous anhydrid, A. Chantemesse (*Rec. Hyg. Pub., 35 (1905), pp. 191–214*).—It often becomes necessary to destroy rats on board loaded freight vessels and in other situations where fabrics and provisions are stored. In such cases the reagent used in killing rats must be of such a nature that it does not cause serious injury to the stored materials. A long series of experiments was carried on with a patented apparatus which uses sulphur dioxid condensed in water in the form of sulphurous acid. The apparatus is claimed to add ozone to the gas during the process of its evolution. For this reason, the resulting gas mixture contains both sulphur dioxid and sulphur trioxid. The gas was employed in the destruction of rats on board vessels loaded with silk, woolen, and cotton goods, skins, rubber, metals, legumes, fruits, preserves, etc. The injury caused to these materials by the fumigation was not serious. The committee which was entrusted with the supervision of the experiments reports that rats are effectively destroyed by means of this apparatus and recommends its use for the purposes specified above.

Destruction of rats, R. Wurtz (*Rec. Hyg. Pub., 35 (1905), pp. 473–483*).—In the series of experiments reported by this author upon the use of a proprietary apparatus for producing sulphur dioxid and sulphur trioxid, it was found that sulphur dioxid alone is as effective as when mixed with sulphur trioxid. Claims for special efficiency from the addition of sulphur trioxid are therefore discredited. No objection, however, is raised to the use of the machine which seems to destroy rats effectively.

Combating rats and mice, Hiltner (*Prakt. Bl. Pflanzenbau u. Schutz, 5 (1907), No. 6, pp. 61–63*).—Brief mention is made of the results commonly obtained in fighting mice and rats with infectious diseases and proprietary forms of virus prepared in different laboratories. The author believes that better results will be obtained from the use of a bait poisoned by barium carbonate.

Hawks and owls from the standpoint of the farmer, A. K. Fisher (*U. S. Dept. Agr., Biol. Survey Circ. 61, pp. 18, figs. 6*).—This circular is a revised form of an article published in the Yearbook for 1894 (E. S. R., 7, p. 470).

Directory of officials and organizations concerned with the protection of birds and game, 1907, T. S. Palmer (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 62, pp. 16*).—This directory contains in a convenient form the names of persons to whom application may be made for information regarding game laws.

List of publications of the Biological Survey, Department of Agriculture, 1907 (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 60, pp. 7*).

Twenty-second report of the State entomologist on injurious and other insects of the State of New York, 1906, E. P. Felt (*N. Y. State Mus. Bul. 110, pp. 39–186, pls. 3, figs. 2*).—During the year under report particular attention was devoted to the insect pests of fruit and shade trees, the gipsy moth, brown-tail moth, gall midges, aquatic insects, and nursery inspection. The occurrence of *Thysania zenobia* is reported in Albany. This insect was apparently imported from South America.

Detailed notes are given on a large number of injurious insects upon which observations were made. These include scurfy scale, San José scale, asparagus beetle, tree crickets, grapevine root-worm, sugar-maple borer, *Contarina violicola*, etc. The last-named insect appears to threaten serious damage to the industry of violet growing. The injuries caused by this pest may be somewhat reduced by maintaining low temperatures in the violet houses during early fall and by careful examination of violets before they are planted. Warnings are issued regarding the possible introduction into New York of gipsy moth, brown-tail moth, and oriental slug caterpillar.

A summary is given of the notes received from voluntary entomological observers throughout the State. The author presents a list of the entomological articles issued by his office during the year and also a list of the insects received for identification and for specimens.

In an appendix to the bulletin descriptions are presented of a large number of new species of Cecidomyiidæ.

Second annual report of the State entomologist, E. F. Hitchings (*Ann. Rpt. State Ent. Maine, 2 (1906), pp. 77, pls. 2, figs. 21*).—A general report on the miscellaneous work of the State entomologist for the year 1906. Particular attention was given to a study of the distribution and means of combating gipsy moth and brown-tail moth in Maine. The San José scale has not yet been discovered in Maine, but it is feared that infestation may take place.

Brief practical notes are also given on apple-tree tent-caterpillar, strawberry weevil, oyster-shell bark-louse, woolly aphis, and various other injurious insects. Mention is made of the interest taken by various local organizations in the work of eradicating insect pests.

Entomological practice, J. Vosseler (*Pflanzer, 3 (1907), No. 5-6, pp. 65-77*).—Attention is called to the important functions of the economic entomologist, particularly in countries where this subject has not been widely promulgated. The present account is largely a description of the work of the zoological laboratory of the biological agricultural institute at Amani. Mention is made of the many difficulties encountered by the economic entomologist in his work.

Notes on insect, fungus, and other pests (*Jour. Bd. Agr.* [*London*], *14 (1907), No. 4, pp. 212-222*).—Biological and economic notes are given on *Smerinthus ocellatus*, *Neoclytus caprea*, *Phaedon betulæ*, carabid beetles, mites, eelworms, larvæ of leaf-mining flies, plant lice, etc.

New genera and species of Aphelininæ, with a revised table of genera, L. O. Howard (*U. S. Dept. Agr., Bur. Ent. Bul. 12, pt. 4, tech. ser., pp., 67-88, figs. 10*).—In the present paper descriptions are given of 20 new species and 5 new genera of Aphelininæ. They are supplementary to those published in a previous bulletin (E. S. R., 7, p. 516). The Aphelininæ have proved to be of great importance in the control of scale insects.

Leaf hoppers—Supplement, G. W. Kirkaldy (*Hawaiian Sugar Planters' Sta., Div. Ent. Bul. 3, pp. 189, pls. 20, figs. 3*).—From the leaf hoppers collected by Koebele, Perkins, and Muir in Australasian countries, Fiji Isles, and China, 58 additional genera and subgenera and 175 species and varieties are described as new. This makes a total of 143 genera and 387 species from the material just mentioned. The author presents technical descriptions of species, analytical tables for their identification, and biological notes.

The anatomy of the proboscis of Stomoxys, J. W. W. Stephens and R. Newstead (*Ann. Trop. Med. and Par., 1 (1907), No. 2, pp. 171-198, pls. 8*).—The methods adopted in making dissection of specimens of Stomoxys are described in some detail. The anatomical features of the various parts of the proboscis and connected structures in this genus are enumerated.

A disease of oats due to Tarsonemus spirifex, L. Guille (*Jour. Agr. Prat., n. ser., 13 (1907), No. 18, pp. 552–556, figs. 4*).—Oats attacked by *Tarsonemus spirifex* show peculiar cigar-shaped enlargements at the apex of the stems. The head of infested oats becomes spirally coiled, but remains shorter than in normal plants, so that it is entirely contained within the sheaf. The author believes that the farmer has neglected cultural methods with oats under the belief that they are not so valuable as other cereal grains and that this neglect favors infestation by the parasitic mite. Liberal use of fertilizers is recommended as a preventive remedy.

Grain weevils, J. R. Inda (*Com. Par. Agr.* [*Mexico*], *Circ. 59, pp. 21, figs. 8*).—Biological and economic notes are given on the grain weevil, various species of pea weevils, and other insects injurious to stored grain. The usual methods of controlling these pests are recommended, including fumigation with bisulphid of carbon.

The pepper weevil, J. R. Inda (*Com. Par. Agr.* [*Mexico*], *Circ. 58, pp. 11, pls. 3, fig. 1*).—Attention is directed to the attacks of *Anthonomus eugenii* upon Chili peppers. It is commonly held that direct application of insecticides is of little use in controlling this pest, but if applied in time Paris green may give fairly satisfactory results. The author recommends that all fallen fruits be collected and destroyed promptly and that rapid growing varieties of peppers be selected.

Fighting the boll weevil by picking up the infested squares, W. Newell (*Crop Pest Com. La. Circ. 15, pp. 4*).—In average seasons when it is possible to produce an early crop of cotton the author would not recommend the additional expense necessary in picking up and destroying infested squares. It appeared impossible, however, to secure an early crop during the present season, and the author, therefore, suggested as a means of preventing the undue ravages of the boll weevil that fallen squares be collected once a week until July 25, and that these squares be destroyed or confined in wire-cloth cages, so as to allow merely the parasitic insects to escape.

The most important factor in solving the boll-weevil problem, A. Mayer (*Crop Pest Com. La. Circ. 16, pp. 8*).—The author maintains that cotton is the most important money making crop of the South. He considers that in the production of large crops in the future, animal industry in the South will contribute largely by increasing the fertility of the soil. Animal industry can be encouraged most in the South by the eradication of the cattle tick, which is, therefore, considered the most important factor in solving the troubles of the cotton planter.

Insect pests of jute, H. M. Lefroy (*Agr. Jour. India, 2 (1907), No. 2, pp. 109–115, pl. 1, fig. 1*).—A considerable number of insect pests have been observed feeding upon jute, but fortunately not all of them are thus far of a serious nature. Particular attention is given to an account of *Caradrina exigua* and *Cosmophila sabulifera*. A number of less important pests are also noted. Specific remedies have not been devised for these pests of jute, but thorough and clean cultivation is suggested as an important preventive treatment.

Some insects injurious to truck crops. The cranberry spanworm. The striped garden caterpillar, F. H. Chittenden (*U. S. Dept. Agr., Bur. Ent. Bul. 66, pt. 3, pp. 21–32, figs. 2*).—*Cleora pampinaria* has been known for some time as an enemy of the cranberry. The insect is described in its various stages. It is distributed from Maine to the Gulf region. It attacks garden and farm crops, orchards, and forest trees. The larvæ feed on the foliage of host plants. The egg and larval stages have not been determined. The natural enemies of the pest are not of much importance, but it may be controlled on asparagus by spraying with arsenicals.

Mamestra legitima feeds on garden plants, particularly asparagus, cruciferous and leguminous plants. Descriptive and economic notes are given on this insect. There are 2 generations annually, and hibernation occurs in the pupal stage. The larvæ may be destroyed by mechanical means or by spraying with arsenicals alone or in Bordeaux mixture.

Fruit flies, C. FRENCH (*Jour. Dept. Agr. Victoria, 5* (*1907*), *No. 5, pp. 301–312, pl.* 1.)—Particular attention is given to an account of the Mediterranean fruit fly, the life history of which has been carefully studied by the author. This insect spends 12 days in the egg stage, 13 days in the pupal stage and 24 days as an adult. Descriptive and economic notes are also given on other species of fruit flies, including *Dacus tryoni*, *Tephritis psidii*, etc.

The author believes that fruit flies have not yet become permanently established in Victoria. It is recommended that kerosene boxes, such as have been used in western Australia, be placed in infested orchards. Careful inspection of imported fruit is also necessary.

The woolly aphis on apple trees, G. D'UTRA (*Rev. Agr.* [*São Paulo*], *12* (*1907*), *No. 143, pp. 243–249*).—Notes are given on the life history of this insect and on the injuries which it causes to apple trees. The greater part of the article is occupied with a discussion of insecticides which may be used in destroying the pest. These include kerosene, crude naphthalin, creosote, alcohol, whale-oil soap, turpentine, etc. Good results were obtained from a mixture containing 1 kg. whale-oil soap and 2 liters of kerosene in 10 liters of water.

Threadworms in grapevines and pear trees, G. KORFF (*Prakt. Bl. Pflanzenbau u. Schutz, 5* (*1907*), *No. 6, pp. 67–69, fig. 1*).—Reports have been received by the author of the finding of threadworms in grapevines and pear trees. These worms proved to be species of Mermis, and attention is called to the fact that they are commonly parasites of insects.

The sphinx of grapevines, R. BRUNET (*Rev. Vit., 28* (*1907*), *No. 707, pp. 5–7, pl. 1*).—Mention is made of the habits, biology, and natural enemies of *Sphinx elpenor* which in some years causes serious damage to grapevines. In combating this pest the adult moths may be attracted to lights and captured in this way. The larvæ are readily destroyed by the application of insecticides. The one especially recommended by the author is a mixture of naphthalin and sulphur.

The destruction of the olive fly, M. DE CILLIS (*Coltivatore, 53* (*1907*), *No. 27, pp. 8–11*).—The mixture previously recommended for the destruction of this fly, while effective, is rather too expensive. The author therefore experimented with a similar poisonous bait and obtained good results from the use of one containing 50 parts molasses, 48 parts grape juice, and 2 parts of arsenicals.

The action of low temperatures on the eggs and caterpillars of Paralipsa gularis, J. DE LOVERDO (*Compt. Rend. Acad. Sci.* [*Paris*], *145* (*1907*), *No. 1, pp. 90–92*).—Almonds in storage, whether decorticated or not, are seriously attacked by the caterpillars of *P. gularis* and also by those of *Plodia interpunctella*. The means commonly used for controlling these insects, particularly the former species, include whitewash and the application of insecticides directly to the stored fruit. These methods have proved unsatisfactory and ineffective. The author, therefore, tested the value of low temperatures in checking the development of the caterpillars. It was found that eggs of *P. gularis* when maintained at temperatures ranging from —3 to +4° C. from April until October did not hatch. Caterpillars kept at about the freezing point for a number of months do not show any of the usual signs of life, although a large percentage of them recover after being removed from cold storage. It is suggested, therefore, that the insects in question may be largely controlled by the application of low temperatures.

White-marked tussock moth and elm-leaf beetle, E. P. FELT (*N. Y. State Mus. Bul. 109, pp. 31, pls. 8*).—These 2 pests are described and notes given on their habits, life history, and natural enemies. The tussock moth may best be combated by collecting the egg masses, banding tree trunks, and spraying with arsenical poisons. The elm-leaf beetle may be controlled by spraying with arsenicals in the spring and by applying contact insecticides to the full grown larvæ at the base of the trunk.

The anatomy and histology of ticks, S. R. CHRISTOPHERS (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1906, No. 23, pp. 55, pls. 6*).—A detailed account of the anatomy and histology of 2 types of ticks is given. These types are *Rhipicephalus annulatus* and *Ornithodoros savignyi.* The literature of the subject is discussed in connection with a brief bibliography. The author also considers the agency of ticks in transmitting disease, the structure of the eggs of ticks, and the essential points in their embryology.

Ticks as distributors of disease, W. DÖNITZ (*Pflanzer, 3 (1907), No. 7, pp. 97–108*).—Attention is given chiefly to a critical review of the results obtained in a study of cattle ticks of various species particularly in Africa, and also of *Argas persicus.*

Note on the occurrence of the North American fever tick on sheep, W. D. HUNTER (*U. S. Dept. Agr., Bur. Ent. Circ. 91, pp. 3*).—It is reported that J. D. Mitchell has observed fully engorged cattle ticks on sheep in 3 counties of Texas. It is suggested that in some localities a pasture might remain infested indefinitely with no host animals for the ticks except sheep. The wounds produced by the ticks on sheep sometimes become infested with the screw worm and require treatment. It has not been determined whether the offspring of cattle ticks which have developed on sheep can transmit Texas fever.

A simple plan of eradicating the cattle tick by the pasture rotation method, W. NEWELL (*Crop Pest Com. La. Circ. 14, pp. 4*).—The plan proposed in this circular is based on the facts that eggs deposited after the beginning of cool weather do not hatch until after the second spring, and that fields cultivated during the summer are free from ticks after the first of December. It is, therefore, recommended that the farmer provide a tick-free pasture for cattle after they have been freed from ticks during the coming winter, and that care be exercised to prevent the reinfestation of such pastures or of the cattle after they have once been freed from ticks.

The Leishman-Donovan body in the bedbug, W. S. PATTON (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1907, No. 27, pp. 19, pl. 1, chart 1*).—In cases of kala-azar the parasites observed in the white blood corpuscles have been suspected of being transmitted by lice, mosquitoes, fleas, and ticks as well as bedbugs. The parasitic bodies may be found in the intestines of *Cimex macrocephalus* allowed to suck the blood of patients affected with kala-azar. It is possible, therefore, that the disease may be transmitted by the Madras bedbug.

On the importance of larval characters in the classification of mosquitoes, S. R. CHRISTOPHERS (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1906, No. 25, pp. 18, pls. 3*).—A system of classification for mosquitoes is proposed upon the basis of larval characters. The author does not claim that the classification is a rigid one, but maintains that the different genera can be grouped together more satisfactorily according to the larval than the adult characters.

An automatic oiler for the destruction and prevention of mosquito larvæ in cesspools, E. H. and H. C. Ross (*Ann. Trop. Med. and Par., 1 (1907), No. 2, pp. 165–167*).—A description is given of a simple apparatus consisting of a crude oil can furnished with 2 openings plugged with cotton and sand so that the water enters the can slowly as the oil is forced outward at the upper opening. The oil passes out of the can at the rate of about 50 cc. daily for nearly 2 months. It is recommended that the automatic oiler be removed and replaced by a new one after 10 weeks. The apparatus costs about 12 cts.

The East African honeybee, J. Vosseler (*Ber. Land u. Forstw. Deutsch-Ostafrika, 3 (1907), No. 2, pp. 15–29*).—Throughout German East Africa there is a race of honeybees considerably smaller than German bees and distinguished by a brownish-red color of the first abdominal ring. Occasionally this brown ring is absent and the bees then resemble the German race of bees except for their small size.

The East African bees are industrious workers and gather honey almost continuously. The seasons for honey-bearing flowers are not as marked as in temperate climates, but while the conditions are favorable for plant growth during the whole year the best condition of honey-producing plants is observed during certain seasons which correspond in a way to our spring and summer.

Scales for weighing beehives, C. Jungfleisch (*Apiculteur, 51 (1907), No. 7, pp. 282–287, figs. 5*).—Recently considerable interest has been manifested in securing a practical type of scales for weighing colonies of bees. The author maintains that it is highly desirable to have such an apparatus, since otherwise it is almost impossible to determine the condition of the colony with regard to the amount of its stores. It is not considered necessary that the scales should be graduated so as to show actual pounds, but should merely indicate whether the colony is increasing or diminishing in weight.

The Caucasian sericultural station; its organization and work from 1887 to 1905 (*Kavkazskaya Shelkovodstvennaya Stantzya cya Ustroistvo i Dyeyatelnost, 1887–1905. Tiflis: Caucasian Sericultural Sta., 1906, vol. 1, pp. IV+537, pls. 36, figs. 113; 1907, vol. 2, pp. IV+517, pls. 5*).—In part 1 a general historical statement is given of the development of sericulture in those countries which are most noted for this industry and of the governmental and other assistance which has been offered for promoting sericulture. Particular attention is directed to a historical account of the organization and development of the Caucasian sericultural station, biographies of the men connected with this work, and the special lines to which they have devoted their energies.

In the second part the work accomplished by the station is discussed with reference to the original contributions made to the science of sericulture, and the practical methods devised and popularized by the officials connected with the station.

FOODS—HUMAN NUTRITION.

Report on bleaching of flour, H. Snyder (*[St. Anthony Park, Minn.]: Author, 1906, pp. 15*).—The deductions which the author drew from the investigations reported follow:

"When flour is bleached by the action of electricity no mineral nitrites are formed, but there is a feeble combination of nitrogen peroxid with water, to the extent of about 0.00003 of a part to 100 parts of flour.

"This gas residue is entirely expelled when the bread is baked in an oven from which all gases of combustion are excluded. Bread made from bleached flour and properly baked contains no trace of the bleaching gas.

"Bread made from unbleached flour and baked in a gas oven in which the oven is connected with the combustion chamber, may contain twice as much nitrites as are present in bleached flour. The nitrites present are derived from the combustion of the gas used as fuel and not from the flour.

"All chemical authorities agree that nitrogen peroxid products alone, or in feeble combination with water, are readily volatilized when warmed.

"Nitrites are present in traces in many food products, particularly in those of vegetable origin. Nitrites are a normal constituent of the saliva and were found present to the extent of from 10 to 20 times the amount found in the heaviest bleached flours. In the case of the bleached flours, however, all of the gas residue is expelled during the process of bread making.

"Flours that have not been bleached, but stored for periods of 1 to 3 months, may show traces of nitrites due to absorption from the air, which contains nitrites in traces as a normal constituent."

Effect of bleaching on the quality of flour, GRENIER (*Bul. Soc. Agr. France, n. ser., 39 (1907), May 15, Sup., pp. 511–518*).—From studies of bleached and unbleached flour stored in different ways, the author concludes that bleaching diminishes the fat content and increases the acidity and that the character of the gluten is also changed. No difference was noted in the keeping qualities of bleached and unbleached flour when stored in jars or sacks and he concludes that there is no reason for bleaching.

On the food plants cultivated by the Umbundu-speaking natives of Portuguese West Africa, F. C. WELLMAN (*Jour. Trop. Med.* [*London*], *10 (1907), No. 9, pp. 157–160*).—Brief descriptions are given of the different sorts of Cruciferæ, Leguminosæ, Cucurbitaceæ, Gramineæ, and a number of other food plants cultivated by the Portuguese West African natives. Indian corn is the most important food crop of the region. The green stalks are chewed like sugar cane for the sweetish sap which they contain, while the green and ripe ears are favorite articles of food. The dry corn is used for making hominy and for meal and is also parched. Rice, Kafir corn, *Pennisetum typhoideum* and *Eleusine coracana* are also cultivated as food grains. The author has summarized in tabular form data regarding the composition of a number of the native foods which he has described.

"In conclusion, it must be pointed out that while the cultivated food plants above mentioned compose by far the greater part of the Umbundus' dietary, yet the people are not vegetarians by choice. Meat of all sorts of game, besides beef, pork, mutton, goat's flesh, fowls, and fish enter into their list of foods whenever obtainable. Rats and mice, locusts, and other insects and their larvæ are also eaten. Many wild fruits, etc., are also eagerly sought."

Concerning fruit juice statistics for the year 1906, F. SCHWARZ and O. WEBER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 6, pp. 345–349*).—Analyses are reported of a number of samples of raspberry juice and sirup prepared by the authors. The work was undertaken with special reference to the examination of such goods with a view to the detection of sophistication.

Canning and preserving, G. MCCARTHY (*N. C. Dept. Agr., Biol. Div., 1907, pp. 37*).—The value of canned fruits and vegetables is briefly discussed and directions are given for the home canning of fruits and vegetables, for making wine, vinegar, etc., and for pickling and preserving meats and fish. The author has also included estimates of the cost of the equipment of a small commercial canning plant.

The constants of whisky, J. H. SHEPARD (*Rpt. Chem. So. Dak. Food and Dairy Com., 1906, pp. 20*).—The analyses reported and discussed were made for the purpose of securing data for the examination of whisky under the pure-food law.

Report on the examination of canned meats (*Mo. Bul. N. Y. State Dept. Health, 23 (1907), No. 4, pp. 2–9*).—Data are reported regarding the examination of 154 samples of canned and potted meats and similar goods collected prior to January 1, 1907. Thirty of the cans examined had only fair meat contents, 25 had low-grade meat contents, and 7 had very poor meat contents, while 1 sample of potted ham was made from diseased meat, the embryos of *Trichina spiralis* being identified.

Changes which take place in eggs, A. Chrétien (*Hyg. Viande et Lait, 1 (1907), No. 5, pp. 193–201.*)—A summary of data on mechanical, physical, and physiological changes in eggs, and those which are brought about by living organisms, particularly by bacteria.

Concerning crab extract, II and III, D. Ackermann and F. Kutscher (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 10, pp. 610–614*).—In addition to the constituents referred to in an earlier report (E. S. R., 18, p. 857), the authors identified hypoxanthin and betain as constituents of crab extract. Sarcolactic acid was also identified, but no succinic acid was found.

Artificial digestion experiments with a number of foods of vegetable origin, W. Rothe (*Ztschr. Physiol. Chem., 51 (1907), No. 3, pp. 185–200*).—Oatmeal, oat grits, barley grits, green wheat grits, rice, bean meal, pea meal, lentils, beans, and other similar materials soaked in water at body temperature were digested with hydrochloric acid and with gastric juice of different strengths.

Considerable differences were found in the foods studied in the amount of protein, which was rendered soluble, owing, in the author's opinion, to differences in their chemical properties. As has been pointed out by other investigators, heating, such as is practiced in the preparation of meal from legumes, renders the protein less soluble, while the reverse is true of the starch, owing to its inversion. Such treatment, however, lessens the time required for cooking. The author points out that some of the digestion coefficients were not what might have been expected; for instance, the protein of meal made from legumes went into solution very readily. Attention is also directed to the fact that the results of the experiments are relative rather than absolute.

The physiological behavior of inosit, P. Mayer (*Biochem. Ztschr., 2 (1907), p. 393; abs. in Chem. Ztg., 31 (1907), No. 31, Repert. No. 27, p. 166*).—As shown by the author's investigations, glycogen is not formed from inosit in the body.

Experimental studies on the nutritive value of meat powder, P. Lassablière (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 13, pp. 640, 641*).—Experiments made with dogs led the author to conclude that meat powder produces harmful effects and can not be considered a foodstuff.

Practical physiological chemistry, P. B. Hawk (*Philadelphia, 1907, pp. XIV+416, pls. 6, figs. 126*).—As the result of class room experience the author has prepared a handbook of physiological chemistry which contains a large amount of valuable material presented in a clear and logical manner. Carbohydrates, salivary digestion, proteids, the decomposition products of proteids, gastric digestion, fats, pancreatic digestion, bile, putrefaction products, feces, blood, milk, epithelial and connective tissues, muscular tissue and nervous tissue, urine, and the quantitative analysis of milk, gastric juice and blood are among the topics taken up. The chemistry of the different compounds under consideration, methods of detection and analysis and related questions are discussed. Special features of the volume are the data on the examination of feces for diagnosis and the discussion of the decomposition products of proteids. The subject of solid tissues has also been treated somewhat more fully than is usual in such textbooks.

The chemical coordination of the activities of the body, E. H. Starling *Sci. Prog. Twentieth Cent., 1 (1907), No. 4, pp. 557–568*).—The important part played by internal secretions in the regulation of the activities of the body has long been recognized by physiologists and available data on the subject are summarized and discussed by the author who, with his associates, has made important contributions to this line of physiological chemistry. He proposes the name "hormones" for these excitatory substances or "Reizstoffe," as they are sometimes called.

"Foodstuffs are valuable in proportion as they furnish energy to the organism or material for its construction and growth. These 'Reizstoffe' are, so far as we can tell, nonassimilable, and yield no appreciable amount of energy. It is their dynamic effects on the living cell which are of importance. In this respect they present a close analogy to the substances which form the ordinary drugs of our pharmacopœias." The author believes that these excitatory substances must be regarded as compounds "produced often in the normal metabolism of certain cells, of definite chemical composition, and comparable in their chemical nature and mode of action to drugs of specific action, such as the alkaloids."

The chemical coordination of body functions, E. H. Starling (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 2 (1907), Nos. 5, pp. 161–167; 6, pp. 209–214*).—This address, delivered before the Society of German Naturalists and Physicians, covers essentially the same ground as the paper noted above.

Experimental studies on psychic and associative secretion of gastric juice in man, H. Bogen (*Arch. Physiol [Pflüger], 117 (1907), No. 1–2, pp. 150–160*).—A secretion of gastric juice can be brought about in man by psychological means and by associative methods. Psychical effects, such as anger and pain, hinder its secretion. The quantity of secretion and duration of the activity of the secreting glands diminishes with a lessening of the intensity of stimulation. The hydrochloric acid and total acidity of the gastric juice are apparently also dependent upon the intensity of excitation.

Chemistry of digestion in the animal body, VIII, E. S. London (*Ztschr. Physiol. Chem., 51 (1907), No. 3, pp. 241–243, figs. 2*).—The author describes a method of operating on animals in order that digestive processes may be studied which he believes will yield good results.

An improved operative method of forming an experimental accessory (Pawlow) stomach in the dog, J. C. Hemmeter (*Amer. Jour. Physiol., 17 (1907), No. 4, pp. 321–325, figs. 6*).—This operation, which is described in detail, is of great importance in studying the physiology of digestion.

Further experiments on the value of deep-seated cleavage products of proteid, E. Abderhalden and B. Oppler (*Ztschr. Physiol. Chem., 51 (1907), No. 3, pp. 226–240*).—In the experiments reported, which were made with dogs, it was found that the products derived by the deep-seated cleavage of casein maintained nitrogen equilibrium for a considerable time.

Cleavage of food proteid in the intestine, II, O. Cohnheim (*Ztschr. Physiol. Chem., 51 (1907), No. 4–5, pp. 415–424*).—As shown by the experimental data reported, the successive action of digestive ferments upon meat protein produces as much arginin as does cleavage with acid.

Cleavage of gliadin by means of Bacillus mesentericus vulgatus, E. Abderhalden and O. Emmerling (*Ztschr. Physiol. Chem., 51 (1907), No. 4–5, pp. 394–396*).—Experiments show, according to the authors, that the cleavage of gliadin to fatty acids and other nitrogen-free cleavage products is due to the fact that the bacillus, aided by its ferments, first changes food protein into amido acids.

Further experiments on the assimilation of protein in the animal body, E. Abderhalden, C. Funk, and E. S. London (*Ztschr. Physiol. Chem., 51 (1907), No. 4–5, pp. 269–293*).—Meat gliadin and egg albumen were the proteids studied in experiments with dogs having Eck fistulæ. In no case was any of the food protein found in the blood, nor could it be shown that the composition of the food protein, and particularly it glutaminic-acid content, had an effect on the protein of plasma, or the proteids of the blood corpuscles. Cleavage products of protein were not found in the blood. (See E. S. R., 18, p. 67.)

Proof of the occurrence of dissolved proteid in adult feces, H. SCHLOESSMANN (*Ztschr. Klin. Med., 60 (1907), pp. 272–294; abs. in Chem. Abs., 1 (1907), No. 6, p. 742*).—The proteid in feces extract which may be precipitated by acetic acid consists principally of nucleo-proteid. Mucin, a substance of weakly reducing properties, is generally present in fresh feces. The nucleo-proteid content of adult feces is not changed by a diet rich in nucleins. In the feces of children such food results in an increased excretion of nucleo-proteid in the feces. Under pathological conditions there is generally an increase in this constituent. With the exception of the body under consideration no other proteid is found in feces in health. The proteid which appears in the feces pathologically is, generally speaking, albumin, though albumoses occur occasionally.

Day and night urines, E. OSTERBERG and C. G. L. WOLF (*Jour. Biol. Chem., 3 (1907), No. 2, pp. 165–169*).—The analytical data reported do not show any regularity in the volume of urine excreted, the excesses of excretion on each diet being equally divided between night and morning urines. Furthermore, no regularity was noted in the nitrogen or in the urea excreted. Except in one instance with a low protein diet the ammonia excreted in the night urine was greater than in the day urine.

The authors believe that their results indicate an increase in the excretion of creatinin in the day urine. "The amount is always higher during hours of work. . . . In each set the elimination of creatin was greater during the day than at night. The uric acid appears to follow to some extent the course of the creatinin, although during one period, the elimination is lower during a waking period."

The undetermined nitrogen of the urine was with one exception greater during the work periods. The elimination of sulphur showed more regularity than that of nitrogen, the total sulphur, total sulphates, and neutral sulphur being uniformly higher during waking than during sleep. In the case of ethereal sulphur, variations were noted, but they were not very large.

The analysis of urine in a starving woman, F. G. BENEDICT and A. R. DIEFENDORF (*Amer. Jour. Physiol., 18 (1907), No. 4, pp. 362–376*).—The observations reported were made with an insane woman who refused food.

"The volume of urine of a fasting woman (without water) may be as low as 237 cc. in 24 hours. . . . The nitrogen output during fasting increased for the first 3 days and then decreased. On one day, at the conclusion of the fast, the subject excreted but 3.17 gm. of nitrogen."

The elimination of creatin, F. G. BENEDICT and V. C. MYERS (*Amer. Jour. Physiol., 18 (1907), No. 4, pp. 406–412*).—Studies with insane patients led to the deduction that the experimental evidence at hand is as yet not sufficient to show clearly the relation between creatin output and disease. The available data would imply that creatin is excreted in wasting diseases where flesh is broken down.

The elimination of creatinin in women, F. G. BENEDICT and V. C. MYERS (*Amer. Jour. Physiol., 18 (1907), No. 4, pp. 377–396*).—The authors' summary of the experimental data presented follows:

"The creatinin excretion of women is, in general, much lower than that of men. While the excretion is, in general, proportional to the body weight, this is not always the case. Age appears to play an important rôle in the excretion of creatinin, since elderly people excrete less creatinin than younger people, with essentially the same body weight. The evidence furnished by the subject whose body weight varied considerably at times implies that the creatinin excretion is proportional to the body weight and not to the active mass of protoplasmic tissue.

Observations on nitrogenous metabolism in man after removal of the spleen, L. B. Mendel and R. B. Gibson (*Amer. Jour. Physiol., 18 (1907), No. 3, pp. 201–212*).—Analytical data reported did not indicate any striking variations from the normal distribution of urinary components which could be associated with the exclusion of the functions of the spleen.

The action of certain drugs on the elimination of uric acid during a nitrogen-free diet, H. C. Jackson and K. D. Blackfan (*Studies Bender Hyg. Lab., 3 (1906), pp. 24–41*).—In the experiments reported the diet consisted of a sort of pudding made from arrowroot, starch, cane sugar, butter fat in the form of cream, salt and extracts and fruits as flavoring material, the total energy value of the diet being 2,811 calories per day. From the standpoint of energy, the diet was found to be sufficient.

The conclusion was reached that the elimination of uric acid on a purin-free or nitrogen-free diet is not a constant value for the same individual. Apparently the elimination of creatinin may be altered by conditions other than that of creatinin in the food. Alcohol was found to increase the output of uric acid during a nitrogen-free diet. Other conclusions are drawn regarding the effect of this substance and of a number of drugs.

Concerning glycolysis, G. W. Hall (*Amer. Jour. Physiol., 18 (1907), No. 3, pp. 283–294*).—The experimental data reported confirm Cohnheim's conclusion that the pancreas alone can not destroy appreciable amounts of δ-glucose; "muscle alone can destroy small quantities of glucose; while small quantities of the expressed juice of pancreas mixed with muscle juice destroy considerable quantities of glucose. Even more effective in this cooperation than pancreas juice is the alcoholic extract of boiled pancreas.

"The active pancreatic substance is completely precipitated by phosphotungstic acid. Under the same circumstances neither arabinose, nor lactose, nor levulose in material quantity is subject to the same destruction.

"The action of bacteria to destroy glucose in these experiments is shown to have been absent by the failure of the mechanism with other sugars and by the proved sterility of the mixture. Trypsin or another constituent of the pancreas has a harmful effect upon the active muscle substance, a fact which may perhaps account for the apparent inhibition sometimes observed.

"In such experiments the use of a mixture of mono- and di-sodium phosphates to preserve neutrality is advantageous."

ANIMAL PRODUCTION.

Cassava: Its content of hydrocyanic acid and starch and other properties, C. C. Moore (*U. S. Dept. Agr., Bur. Chem. Bul. 106, pp. 30*).—Analyses were made of a number of varieties of cassava grown in Mississippi and Florida. The results suggest that the hydrocyanic-acid content may undergo a variety of changes during the growth of the plant and may even disappear entirely at times and again be present. In Florida-grown samples the maximum hydrocyanic-acid content appeared to be present about the middle of March.

"It is generally believed that the common stock of cassava known as the Florida Sweet is always sweet, and also that any variety brought into Florida will eventually become sweet. None of the common Florida varieties examined has shown more than a small quantity of hydrocyanic acid, and it appears therefore that the popular belief is well founded. The general results of the work indicate that the environment in Florida is such as to retard the chemical-physiological action which produces the hydrocyanic acid. It may be shown later that continued cultivation under such conditions will change the nature of the plant in this respect."

From a study of the form of tubers with reference to quality the author concludes that the oval form is preferable, as it is better adapted to harvesting and handling and contains a minimum percentage of surface or cortical layer, which would indicate an increase in the starch content and a decrease in hydrocyanic acid.

Experiments were made on the possibility of drying and grinding cassava on a small scale, the drying being carried on in trays. The mill used, when complete with shaft, box, and pulley, would cost $10 and would grind a ton of tubers in 1.5 hours. It was found that when dried under favorable conditions fine white meal was obtained, but if drying was prolonged the meal was discolored.

"When used for stock feeding, this discoloration is not objectionable. The greatest shrinkage in weight which occurred was 60 per cent, the meal then containing 8 per cent of moisture, and the average reduction in weight was 50 per cent.

"Meal prepared in this manner and kept for eight months has shown no signs of deterioration, which means that the product can be stored and marketed to much better advantage, and that the cost of transportation, which is one of the principal factors in the profitable production of this crop, has been reduced one-half."

The possibility of the meal being poisonous if used as cattle feed through the liberation of hydrocyanic acid was studied by treating 540 gm. with water and distilling. Only a trace of hydrocyanic acid was found in the distillate.

The importance of cassava meal as a human food, and other questions concerned with yield and varieties, are considered.

The value of feeding materials (*Oklahoma Sta. Rpt. 1907, pp. 34–38*).— Under the provisions of the State law, 26 samples of feeding stuffs were analyzed, including condimental stock and poultry foods and cotton-seed and linseed meal. With regard to the patented stock foods, attention is drawn to the fact that with one exception the samples analyzed were very low in both protein and fat and that they have a feeding value equal to about one-third that of cotton-seed or linseed meal.

"As a medicine or tonic for stock, it is claimed that these foods prevent or cure diseases, fatten run-down stock, aid other foods in the laying on of fat, cause milch cows to give more and richer milk, and reduce the net cost of flesh put on animals during the fattening period. These claims are enormously exaggerated and actual experiment has proven that in most cases these foods are of no value whatever as flesh or milk producers. Foods of this class sell for 10 to 25 cts. per pound and any farmer could duplicate them at a cost of about 1 ct. per pound in most cases. Preparations advertised as foods and medicines are open to suspicion, and when sold as high-class foods and at the same time the claim is made that they are a panacea for all kinds of live-stock ailments they should be condemned.

"Some of these foods contain a laxative, such as Epsom or Glauber's salts, in amounts equal to 15 to 25 per cent of the entire weight. Most of them contain an irritant or stimulant, such as large quantities of pepper, mustard, bark, or charcoal. Table salt is usually present in large quantities. The greater bulk of these foods consists of corn and wheat brans, ground grain, or greater or less quantities of linseed meal. Oat hulls, pine and poplar bark, lime, Venetian red, and ground oyster shells are some of the substances found in foods of this class. Nearly all of them contain some such substance as anise, fenugreek, or fennel to give them an odor. A few of them contain, in small quantities, a valuable tonic such as gentian.

The digestibility of molasses feeds, H. J. Patterson and R. Outwater (*Maryland Sta. Bul. 117, pp. 259–290*).—Using steers as subjects the effects of molasses on the digestibility of hay and on the digestibility of a mixed-grain ration were studied, as well as the digestibility of two commercial molasses feeds and the influence of molasses on the metalbolism of nitrogen.

The results given in the following table are the average for four animals in every case except for hay and molasses, where only two steers were used:

Coefficients of digestibility of rations with and without molasses—Experiments with steers.

Kind of ration.	Dry substance	Protein.	Crude fiber.	Nitrogen-free extract.	Fat.	Sugars before inversion.	Sugars after inversion.	Ash.
	Per ct.	*Per ct*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Hay	48.4	44.3	51.3	47.0	32.1	78.9	84.0	17.2
Hay and molasses	57.6	38.3	52.9	63.7	27.0	94.6	97.7	14.1
Mixed grain	64.9	67.1	16.8	72.1	93.3	107.1	103.6	18.1
Mixed grain and molasses	78.9	71.5	40.2	88.6	102.0	98.9	99.9	49.4
Sucrene	66.9	65.2	34.1	75.4	97.5	97.9	97.7	39.1
Mueller's molasses grains	68.1	57.3	28.9	83.2	102.8	99.8	100.4	38.8

The conclusions which were drawn follow:

"These results show that the addition of molasses to a ration has a tendency to increase the digestibility of both hay and grain feeds. This, coupled with the generally observed fact that molasses contributes toward making feeds more palatable and also acts as an appetizer, gives to molasses a relatively high place as a stock food and makes it more valuable than its analysis alone would indicate.

"The results obtained with sucrene and Mueller's molasses grains, when compared with those obtained for the mixed-grain ration used, show quite evidently that the molasses which they contain has contributed toward making them more digestible and giving them a higher feeding value than they would have had without the molasses. The mixed-grain ration used contained a greater variety of grains than is used by most dairymen and probably average well with any in quality, yet both the sucrene and Mueller's molasses grains showed a higher digestibility.

"In studying these figures the point is noticed that the protein is sometimes not so digestible in the presence of molasses, and this suggests the thought that it may be that the presence of the readily available energy of the molasses has filled the requirements of the animal and thus not necessitated the breaking up of more difficult protein compounds."

The recorded data do not show that molasses exercised any effect upon the metabolism of nitrogen. The feeding stuffs used were analyzed.

Feeding experiments with cattle, sheep, swine, and horses, R. W. Clark (*Utah Sta. Bul. 101, pp. 165–179, 188–201*).—The principal question studied was the value of sugar-beet pulp for farm animals, though tests of the value of apples for pigs and of gains made by different breeds are also reported.

In a test of the value of beet pulp and alfalfa with and without grain made with 5 lots of 5 steers each the greatest gain per head per day in a 70-day period, 2.06 lbs., was made by a lot fed a daily ration of alfalfa and beet pulp ad libitum with 4 lbs. of grain, and the smallest gain, 1.37 lbs., with a lot fed alfalfa and beet pulp ad libitum without grain. The gain was most expensive, costing 7.31 cts. per pound, on alfalfa and beet pulp ad libitum, and was least expensive, costing 3.83 cts., on alfalfa ad libitum and one-half as much pulp.

In a similar test made with 6 lots of 15 sheep each the gains ranged from 0.2 lb. per head per day with the lots receiving, respectively, alfalfa and beet pulp ad libitum with and without 0.5 lb. of grain per head per day to 0.31 lb. per head per day with the lot receiving alfalfa and beet pulp ad libitum with 1 lb. of grain. Gain was most expensive with the last-mentioned lot, costing 5.15 cts., and was cheapest, 3.18 cts., with the lot fed alfalfa and a half ration of beet pulp.

When sugar beets were added to alfalfa and grain a lot of 4 steers made an average daily gain of 1.56 lbs. per head in a test covering 100 days, while 5 steers fed a similar ration without sugar beets gained 1.13 lbs. The cost of a pound of gain in the 2 cases was 9.6 and 7.3 cts., respectively.

When similar rations were tested with sheep the average daily gain with beets was 0.35 lb. per head and without beets 0.22 lb., the period covering 137 days. The cost of a pound of gain in the 2 cases was 6.9 and 5.7 cts., respectively.

To secure data regarding the effects of beet pulp on the strength of bone a lot of 3 wethers was fed 10 lbs. of pulp per head per day, while a similar lot received no pulp. The strength of a number of the more important bones was determined with a testing machine and in every case it was found that there was a difference in favor of the pulp ration.

Beet pulp as part of a ration was studied with 2 pairs of work horses for 2 periods of 28 days each, one horse in each team receiving pulp and the rations being reversed during the second period. An average loss of 6 lbs. per head was noted on the pulp ration and of 2 lbs. on the ration without pulp. "As high as 20 lbs. of pulp was fed to horses per animal per day without any apparent injury. In a ration of alfalfa hay and oats 9 lbs. of well-fermented solid pulp saved 1.5 lbs. oats. . . . The horses took to the pulp reluctantly and their appetite for it gradually decreased." Colts have been allowed constant access to pulp, according to the author, for several years and in no instance has trouble arisen from it so far as is known.

In tests of the value of sugar-beet products for pigs it was found that 5 pigs, fed green alfalfa, skim milk, and shorts, with molasses, made an average daily gain of 1.03 lbs. per head in a 58-day feeding period as compared with 0.85 lb. per head per day with a lot of 4 pigs fed a similar ration without molasses. The cost of a pound of gain in the 2 cases was 2.43 and 2.92 cts., respectively.

In a second test shorts with and without beet pulp, with sugar beets, and with pulp and molasses were compared in a period covering 48 days. The gains ranged from 1.2 lbs. per head per day on both the shorts and beet pulp and the shorts and sugar-beet rations to 1.73 lbs. on shorts alone, and the cost from 2.21 cts. on shorts, pulp, and molasses to 3.71 cts. on shorts and sugar beets.

When shorts and skim milk with and without beet pulp or sugar beets were studied the smallest gain, 1.07 lbs. per pig per day, was made by the lot fed the skim milk and beet-pulp ration, and the greatest gain, 1.36 lbs., by the lot fed shorts and skim milk only. The gain was least expensive, costing 3.38 cts. per pound, on shorts, skim milk, and beet pulp, and most expensive, costing 3.93 cts. per pound, on shorts, skim milk, and sugar beets.

When apples as part of a ration were fed to pigs receiving shorts and skim milk the average daily gain per head in 2 tests with apples was 1.6 lbs. and without apples 1.4 lbs. The calculated value of the apples, according to the author, ranged from nothing to 18 cts. per 100 lbs.

When apples and shorts were fed in comparison with pasturage and shorts to 2 lots of 3 pigs each they were found to have a feeding value about equal to grass, the average daily gain being 0.59 lb. per pig on the apple ration and 0.56 lb. on pastaurage.

In a grazing experiment covering 107 days made to study the relative merits of different breeds of pigs, the results were very similar, ranging from 0.7 lb. per head per day with Yorkshires to 0.78 lb. with Tamworths. "As grazers, pure-bred Tamworth swine were most superior. Berkshire, Poland China, and Tamworth grades were about equal. Pure-bred Yorkshires were not equal to the other breeds in feeding qualities, especially as grazers."

From a summary of data regarding the cost of raising pigs and cattle the following deductions were drawn:

"The average cost of spring litters of 6 pigs each, including the cost of the keep of the sow for one year, when disposed of at a weight of 893 lbs., was $29.42. The average cost of fall litters of 7 pigs each, including the cost of the keep of the sow for one year, when disposed of at a weight of 1,088 lbs., was $36.90. The cost per hundred for spring pigs from weaning to a weight of 150 lbs. was $2.70, and of fall pigs fed through the winter to a weight of 135 lbs. was $2.77.

"The average cost of raising cattle to one year of age was $19 per head, and to two years of age, at which time they averaged 1,037 lbs. in weight, was $36.97."

Tests similar to those noted above were also made with milch cows. (See p. 369.)

Experiments in swine feeding. The value of corn and supplementary feeds for pork production, W. J. Kennedy and E. T. Robbins (*Iowa Sta. Bul. 91, pp. 61, figs. 23*).—Corn meal alone and with varying proportions of ground barley, wheat shorts, meat meal, and tankage was compared in tests with pigs, as were also the relative merits of dry-lot feeding and pasturage and of timothy and clover pasturage.

Four lots of 12 well-grown pigs each were used in the first test, comparing corn alone and with supplementary feeds, and the daily gains made in 32 days on the several rations were per head as follows: Corn, 1.88 lbs.; corn, barley, and shorts 2:1:1, 2.21 lbs.; corn and meat meal 9:1, 2.68 lbs.; and corn and tankage 9:1, 2.34 lbs.

When different amounts of meat meal supplementing corn meal were studied with 4 lots of 9 young pigs each, the average daily gain per head was 1.16 lbs. on corn meal alone, 1.75 lbs. on corn meal and meat meal 7:1, 1.79 lbs. on corn meal and meat meal 8.5:1, and 1.86 lbs. on corn meal and meat meal 10:1.

The feed eaten per pound of gain in the above 2 tests ranged from 3.7 lbs. with the mature pigs on corn and meat meal 9:1 to 5.57 lbs. with young pigs on corn meal alone. The gain was most expensive with the latter lot, costing 3.97 cts. per pound, and was least expensive, costing 3.15 cts., with the mature pigs fed corn meal, barley, and shorts.

A comparison of dry-lot feeding and pasturage and of the effects of supplementing corn by other concentrated feeds under these conditions was undertaken with 10 lots containing 10 pigs each at the beginning of the trial, the test as a whole covering 112 days. When corn and shorts 2:1 and 1:1, corn meal and meat meal 5:1, and corn meal and tankage 5:1 were fed with timothy pasturage, the average daily gain ranged from 1.12 lbs. on corn and shorts 2:1 to 1.37 lbs. on corn and tankage 5:1. In the case of the same rations fed without pasturage the gain ranged from 0.81 lb. on corn and shorts 2:1 to 1.09 lbs. on corn and meat meal. On corn and timothy pasturage alone the average daily gain was 0.92 lb. per pig and on corn and clover pasturage 1.19 lbs. Considering all the lots the concentrated feed eaten per pound of gain ranged from 3.98 lbs. with the lot fed corn and shorts 1:1 on timothy pasturage to 5.12 lbs. with the lot fed corn and shorts 2:1 in a dry yard, and was on an average 4.29 lbs. The cost of a pound of gain ranged from 3.35 cts. with the lot pastured on clover and fed corn to 4.46 cts. with the lot on corn and shorts 2:1 fed in a dry yard, and was on an average 3.92 cts.

In these tests data are given regarding the shrinkage on slaughtering and the profits are discussed at length on the basis of corn meal, meat meal, and tankage at different prices. Some of the conclusions which were drawn follow:

"Meat meal and tankage of similar chemical composition are almost equal, pound for pound, as a supplement to a corn ration for growing pigs and fattening hogs. . . .

"At the prevailing market prices, a ration of corn alone on timothy pasture produced the cheapest gains in weight of any of the rations fed to pigs on timothy pasture, but the mixed rations produced the greatest total net profits.

"Hogs fed on rations composed of corn and meat meal and corn and tankage were fully as acceptable to the buyers, both from the standpoint of the quality and condition of the flesh, as those fed on any of the other rations tested. . . .

"Both meat meal and tankage are more valuable and profitable adjuncts to the corn ration for dry-lot feeding than when pigs or hogs are being developed and fattened on pasture, especially if the pasture be composed of leguminous crops. . . .

"For feeding pigs on pasture with feeds at the prevailing prices, a ration of corn alone produced 100 lbs. of gain at a smaller cost than a ration of corn and shorts. The corn and shorts ration, however, yielded somewhat the greater total profit, due to the more rapid gains produced from the use of the same.

"At the prevailing market price, barley proved to be an economical feed when combined with corn and shorts for finishing hogs for market.

"Pigs on timothy pasture ate more concentrated feed and gained more rapidly than pigs eating the same kind of concentrated rations in dry lots. . . .

"The gains due to the pasture itself were greatest when relatively smaller amounts of protein were supplied in the concentrated part of the ration, and amounted to 278 lbs. of pork per acre from timothy pasture when a concentrated ration composed of 2 parts corn and 1 part shorts was fed after 1.85 tons of hay had been harvested four weeks before the experiment commenced. The ration composed of corn and clover pasture produced 116 lbs. more pork per acre than the ration composed of the same number of pounds of corn and timothy pasture. . . .

"In dry-lot feeding the most rapid gains and the most economical gains were obtained in these experiments from those rations containing a much larger proportion of protein to the carbohydrates and fats than is found in corn. The price which feeders can afford to pay for supplementary feeds, rich in protein, to add to the corn ration for the purpose of balancing the same must be regulated by the percentage of digestible protein contained in them and the market price of corn. When corn is high in price, supplementary feeds, as a rule, can be had at prices which will not prohibit their use; but when corn is very low in price the feeder will very likely lose a portion, if not all, of his profits in pig feeding through the purchase of supplementary feeds."

The feeding stuffs were analyzed.

Experiments in swine feeding, L. E. CARTER (*Iowa Sta. Bul. 91, popular ed., pp. 17*).—A popular edition of the above.

Pig feeding, J. J. VERNON and J. M. SCOTT (*New Mexico Sta. Bul. 62, pp. 20, pls. 4*).—A test was made of the value of different proportions of alfalfa hay and corn and of alfalfa alone with 4 lots of 7 pigs each. In 73 days the pigs on alfalfa and corn 1:3 made an average daily gain of 1.02 lbs. per head, on equal parts of alfalfa and corn of 1.02 lbs., on alfalfa and corn 3:1 of 0.59 lb., and on alfalfa alone 0.21 lb. The feed required per pound of gain ranged from 4.87 lbs. on alfalfa and corn 1:3 to 15.67 lbs. on alfalfa alone. The gain was most cheaply made at a cost of 4.51 cts. per pound on alfalfa and corn 3 : 1 and was most expensive on alfalfa alone, costing 5.48 cts. per pound.

In a supplementary period of 31 days the lot which had been fed alfalfa alone was given a ration of alfalfa and corn 1 : 1.2, and made an average daily gain per head of 0.85 lb. at a cost of 6 cts. per pound, and requiring 6.78 lbs. of feed per pound of gain.

The calculated return per ton of alfalfa hay ranged from $4.93 for the lot fed alfalfa hay alone to $34.68 on alfalfa and corn 1 : 3.

"Hog raising in New Mexico is an undeveloped industry, although the conditions are very favorable in many sections.

"Alfalfa, the leading crop in New Mexico at the present time, forms an excellent pig feed when combined with grain.

"Alfalfa fed alone is a very poor food for fattening pigs.

"In order to prevent undue waste when feeding alfalfa to pigs, the hay should be fed in a slatted rack placed in a flat bottomed trough. The spaces between the slats should not exceed 2.5 inches and the trough should extend at least 18 in. beyond the rack in every direction. The coarse stems left by the pigs may be fed to stock cattle."

The bulletin contains some notes on swine diseases, though the authors state that up to the present New Mexico pigs have not been seriously menaced by diseases.

Animal husbandry, J. J. Vernon (*New Mexico Sta. Rpt. 1906, pp. 24–29*).—An experiment on pig feeding is reported which has been noted from another publication. (See p. 366.)

Finishing hogs for market, C. L. Willoughby and P. N. Flint (*Georgia Sta. Circ. 61, pp. 8, figs. 2*).—With a view to studying the possibilities of producing fat and lean carcasses a pig weighing 138 lbs. was started on a ration of 5 lbs. shorts, 2 lbs. bran, and 6 lbs. skim milk in comparison with a similar pig on a ration of 7 lbs. of shelled corn per day, the quantities in each case being increased as the test continued. In 61 days the pig fed the mixed ration made an average daily gain of 1.08 lbs., while the pig fed the fattening ration of corn gained on an average 1.07 lbs. per day. The cost of a pound of gain in the 2 cases was 8.7 and 8.8 cts., respectively, and the digestible nutrients required per pound of gain 4.67 and 5.59 lbs. The proportion of dressed weight to live weight was practically the same for the 2 pigs, being 77 and 78 per cent, respectively. The pig fed corn showed considerably more lard and body fat than the pig fed the mixed ration. The authors' conclusions follow:

"Hogs fed on protein material such as shorts and skim milk will make more muscle and better bone than hogs fed on a diet of corn.

"It requires less feed (digestible) to produce the same gain when using a large percentage of protein than when feeding corn alone.

"A large share of the flesh is converted into lean meat when feeding a protein ration; a corn ration produces considerably more lard and cheap body fat.

"The cheapest method of raising pigs from weaning time is to use good range, pasture, forage and root crops, with a small quantity of grain. This gives a start toward lean meat production.

"Although certain breeds belong pre-eminently to the bacon or lean meat type, yet all hogs at present grown in Georgia can be fed so as to produce the lean type of carcass by properly balancing their feed with protein materials during the final finishing or fattening period.

"Local butchers and the consumers of pork should be educated as to the superior merits of animals finished by the 'lean meat' method of feeding; and the producers of this class of meat should soon ask and secure a higher price per pound for their product than for pork that is fattened by the exclusive corn method."

Poultry experiments, J. DRYDEN (*Utah Sta. Bul. 102, pp. 203–228, figs. 8*).—Continuing earlier work (E. S. R., 17, p. 390) studies were made of the effects of housing on egg fertility and of the effects of a number of conditions during incubation on the proportion of eggs which hatched, and related questions.

The average fertility of eggs laid by hens in a house artificially heated in winter and in an open-front house was each 70 per cent, in a house with no artificial heat 77 per cent, and in a colony house with free range 74 per cent. The percentage of fertile eggs hatched ranged from 33 with the hens in a house artificially heated to 55 in the case of those in an open-front house, and the weight per egg from 1.89 oz. in the case of pullets in an open-front house to 2.15 oz. in the colony house with the free range. On the whole the results are in favor of the colony house as regards egg yield. The fowls in the colony house had free range, and in every other case they had access to yards, and during the winter, when snow was on the ground, were given no water. "They apparently did not suffer from the eating of snow or the lack of water."

In tests to determine the effect of medium and maximum moisture content of the air of incubators as compared with no moisture, it was found that "Nearly 100 per cent better hatches were obtained by the use of moisture, and there was no contradiction in all of the tests." The relative humidity of the air in the "no moisture" machines was about 51° and in the other incubators about 57°. The relative weight of the chickens hatched in the "maximum moisture" incubator was 1.184 oz., in the "medium moisture" incubator 1.159 oz., and in the "no moisture" incubator 1.072 oz. The weight of a hen-hatched chick was 1.258 oz. The results of these weighings "would indicate that vigor in the chicks demands a greater amount of moisture during incubation than the incubator, as at present made, can furnish." The author also believes that proper germ development does not take place unless the humidity conditions are favorable, for the records obtained show that a larger number of eggs were removed as infertile or having dried germs from the dry than from the moist incubators.

The evaporation from the eggs in the machine with maximum moisture was 12.28 per cent, in that with medium moisture 14.05 per cent, and in that with no moisture 17.78 per cent.

When trays of water were used as a source of moisture instead of trays of moistened sand, the relative loss of weight in eggs during incubation was 16.13 as compared with 12.28 per cent. "The sand is therefore more effective as an evaporating surface than water."

Tests were made of the amount of carbon dioxid in the air of the incubators, but in the author's opinion the values obtained apparently do not bear any relation to the number of chicks hatched. Tests of the air under sitting hens showed 141.1 parts of carbon dioxid per 10,000 parts of air, and practically the same amounts of carbon dioxid were found with a hen sitting on china eggs as on hens' eggs, so "there seems to be no question from these results that the hen gives off large quantities of carbon dioxid from her body." The fact that in incubators the carbon dioxid found comes largely from the eggs, while in natural incubation it comes from the hen's body "indicates a vital difference in the conditions of artificial and natural incubation." On the whole, the investigations "have shown large quantities of carbon dioxid in natural incubation and relatively small amounts in artificial incubation, but increasing artificially, the supply of carbon dioxid seems rather to have an injurious effect in artificial incubation."

Poultry division, F. B. LINFIELD (*Montana Sta. Rpt. 1906, pp. 124–127*).—Improvements in the station poultry plant are described and the egg records of 14 pens of station poultry recorded. The principal object of the station poultry work is the development of large laying strains of different breeds.

A gasoline heated colony brooder house, J. E. Rice and R. C. Lawry (*New York Cornell Sta. Bul. 246, pp. 137–176, figs. 22, plans 7*).—Detailed plans are given for the construction of a brooder house and heating appliances using gasoline as fuel, which have given good results. Data are also included regarding the evolution of gasoline heaters, the construction, operation, and comparative value of different burners, and related questions.

In the authors' opinion there is no danger in operating a gasoline burner provided ordinary care is observed. "The common points of error often resulting disastrously are: (*a*) Allowing too much gasoline to run into the generating cup; (*b*) applying a match to the generating cup before the control valve is closed; (*c*) attempting to light the burner after it has been blown out by the wind or in some other manner and the bottom of the burner box is covered with gasoline."

New poultry appliances, J. E. Rice and R. C. Lawry (*New York Cornell Sta. Bul. 248, pp. 205–228, figs. 37*).—Detailed descriptions are given of a number of poultry appliances, including a trap nest, a feed and a gravel hopper, feed supply can, egg distributing table and carrying box, combination crate for eggs and dressed poultry, water pan and cover, device for carrying kerosene oil to incubator cellar, catching hook, chicken feed trough, a removable floor for chicken shelter, and a system for keeping laying records.

Different methods of preserving eggs, R. Nourissé (*Les Divers Procédés de Conservation des Oeufs. Paris: Société d'Editions Techniques, 1907; rev. in Hyg. Viande et Lait, 1 (1907), No. 5, pp. 222, 223*).—The preservation of eggs by cold storage and by different preservative solutions, evaporated eggs, and related questions are considered.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Feeding sugar beets and sugar-beet pulp to dairy cows, R. W. Clark (*Utah Sta. Bul. 101, pp. 159–165, dgms. 2*).—In experiments on the feeding of sugar beets, the quantity of beets fed was small at the beginning but gradually increased until the cows, averaging about 1,100 lbs. in weight, consumed 30 to 40 lbs. of the beets each per day. The total ration per cow in the average of the experiments of 2 years was 21 lbs. of alfalfa, 5.9 lbs. of grain, and 33 lbs. of beets per day. The corresponding ration without beets was 25 lbs. of alfalfa and 5.9 lbs. of grain. The cows produced a little more milk and butter fat on the ration with beets than on that without them. The food cost of the milk was 77 cts. per hundred pounds and of the butter fat 18.9 cts. per pound with the former ration, whereas it was 50 cts. per hundred pounds for the milk and 12.8 cts. per pound for the butter fat with the latter ration. The milk flow was maintained as well with one ration as with the other.

In similar experiments with beet pulp, cows consuming 25 lbs. of alfalfa, 5.3 lbs. grain, and 28 lbs. of pulp each produced milk at 49.2 cts. per hundred pounds and butter fat at 12.9 cts. per pound, whereas on the same ration without pulp they produced milk at 44 cts. per hundred pounds and butter fat at 12.3 cts. per pound.

From his experiments the author concludes that (1) sugar beets and beet pulp for dairy cows are nearly equal in value; (2) the milk from beet and pulp-fed cows was a trifle higher in butter fat, the increased percentage being very small, and (3) the milk flow and daily yield of butter were maintained as well without beets and pulp as with them.

Feeding different amounts of grain to dairy cows, R. W. Clark (*Utah Sta. Bul. 101, pp. 179–188*).—Cows averaging 1,178 lbs. in weight produced more milk and butter fat on a ration of 12 lbs. of alfalfa and 15 lbs. of grain per day than with a ration of 25 lbs. of alfalfa and 4 lbs. of grain, but in the former case the food cost of the milk was 83 cts. per hundred pounds and of the butter fat 18.7 cts. per pound as compared with 53 cts. per hundred pounds for the milk and 13 cts. per pound for the butter fat in the latter ration.

Cows averaging 1,035 lbs. in weight produced milk at a food cost of 53 cts. per hundred pounds and butter fat at 12.9 cts. per pound on a daily ration of 23.1 lbs. of alfalfa and 8 lbs. of grain, whereas on a ration of 26.3 lbs. of alfalfa and 4 lbs. of grain they produced milk at 85 cts. per hundred pounds and butter fat at 11.3 cts. per pound.

With cows averaging 1,045 lbs. in weight and receiving a daily ration of 17.1 lbs. of alfalfa, 9.8 lbs. of grass hay, and 4 lbs. of grain the food cost of 100 lbs. of milk was 47 cts. and of 1 lb. of butter fat 12.4 cts. On a daily ration of 16.6 lbs. of alfalfa, 10 lbs. of grass hay, and 8 lbs. of grain the cost was 57 cts. per hundred pounds for the milk and 15 cts. per pound for the butter fat.

The author concludes from his experiments that the daily yield of milk and of butter fat was greater and the milk flow was maintained better on the larger than on the smaller amount of grain fed with alfalfa, but that the milk and the butter fat were produced cheaper with the smaller grain ration. In these experiments 13 lbs. of good alfalfa hay was nearly equal in value to 11 lbs. of grain, as a supplement to a basal ration of 4 lbs. of grain and 12 lbs. of hay.

Milking machines, W. A. Stocking, Jr., C. J. Mason, and C. L. Beach (*Connecticut Storrs Sta. Bul. 47, pp. 101–138, figs. 10*).—Part 1 of this bulletin, by W. A. Stocking, jr., and C. J. Mason, gives the results of studies of the effect of milking machines upon the quality of milk and part 2, by C. L. Beach, studies of the effect upon milk yield.

Effect upon quality of milk.—In 9 experiments the milking machine was treated in different ways and the bacterial content of the machine-drawn milk was compared with that of hand-drawn milk.

In the first experiment the machine was at night simply rinsed by pumping warm water through it and after use in the morning taken apart, scrubbed with hot water and washing powder, and rinsed with clean water. The pails were sterilized by steam. The bacterial content of the machine-drawn milk averaged 15,524 per cubic centimeter and of the hand-drawn milk 3,144.

The machine was next treated as in the first experiment but in addition the rubber tubes and teat cups were kept from morning until evening in a 1 : 300 solution of a washing powder. The bacterial content of the machine-drawn milk averaged 43,122 per cubic centimeter and of the hand-drawn milk 18,729.

In the third experiment the tubes and cups were kept in a 2.5 per cent solution of formalin between milkings, other conditions being the same as in the previous experiments. The tubes were made practically sterile by this treatment and the rubber was not injured. The tin-covered teat cups, however, were somewhat corroded. The average bacterial content of machine-drawn and hand-drawn milk was respectively 20,225 and 23,329 bacteria per cubic centimeter.

In the fourth experiment all parts of the machine were sterilized by steam. This was found very injurious to the rubber. The average bacterial content of the machine-drawn and hand-drawn milk was respectively 19,984 and 18,172 bacteria per cubic centimeter.

In the fifth and following experiments a new style of connector was used, which admitted air into the teat cups to relieve suction. The tubes and cups were kept in a 10 per cent salt solution between milkings. This treatment did not render the tubes sterile, and the brine itself was found to increase in germ content from day to day. The machine-drawn milk contained on an average 12,962 bacteria per cubic centimeter and the hand-drawn milk 10,806.

The tubes and cups were next kept in a borax solution made by dissolving 1 lb. of borax in 15 qt. of water. This did not sterilize the apparatus. The machine-drawn milk contained 17,817 bacteria per cubic centimeter and the hand-drawn milk 8,767.

In the seventh experiment the authors returned to the formalin treatment, using 3.5 per cent, but still the machine-drawn milk contained more bacteria than the hand-drawn milk, the averages being, respectively, 7,857 and 6,355 bacteria per cubic centimeter.

The formalin treatment was continued in the next experiment, but the air taken into the teat cups was filtered through absorbent cotton. This reduced the bacteria in the machine-drawn milk to 1,578 per cubic centimeter, while the average number in the hand-drawn milk was 4,560. In a second series in which the cotton filters were omitted the average bacterial content of the machine-drawn milk was 11,521, and of the hand-drawn milk 7,467.

In the final experiment lime water was used in the place of the formalin solution. The bacterial content of the machine-drawn milk was 55,367 and of the hand-drawn milk 5,908.

The formalin treatment was, therefore, the only one tried which was efficient in sterilizing the apparatus and at the same time was not injurious to the rubber.

In most cases the machine-drawn milk, notwithstanding the bacterial content was frequently higher, kept sweet longer than the milk drawn by hand.

Effect upon milk yield.—This part of the bulletin gives the yield of cows milked by hand and by machine. The results are submitted without discussion or comment, the work being considered too limited to warrant any conclusions.

Comparative studies with covered milk pails, W. A. Stocking, Jr. (*Connecticut Storrs Sta. Bul. 48, pp. 73–103, figs. 12*).—The author has tested several styles of covered milk pails taking the number of bacteria in the freshly drawn milk as an indication of the amount of external contamination. The different pails used are described and illustrated. The general conclusions drawn from the work as a whole are as follows:

"The use of the covered milk pail is of great advantage in any stable in excluding dirt and bacteria from the milk. The relative advantage gained by the use of the cover depends upon the sanitary condition of the stable.

"The special form of cover does not seem to be important provided it is a device practical for use and the area through which dirt can gain access to the milk is reduced as much as possible.

"Whether or not a strainer on the covered pail is desirable depends upon the style of the straining device.

"The use of the strainer in a pail where the dirt which falls into the opening is likely to be driven through by the succeeding streams of milk is not desirable. Its use tends to increase the germ content of the milk and injure its keeping quality.

"In pails where the dirt which falls in does not remain where the succeeding streams strike against it a strainer cloth aids in keeping down the number of bacteria which gain access to the milk. . . .

"The use of absorbent cotton as a strainer . . . is a decided advantage in preventing the entrance of bacteria into the milk."

Biological and biochemical studies of milk. V, Enzyms, C. J. Koning (*Milchw. Zentbl., 3 (1907), No. 6, pp. 235–261, figs. 2*).—The catalase content of milk, according to the author, increases with the age of the cow and with the bacterial content of the milk. His experiments indicated that this enzym is not produced by lactic-acid bacteria but by other organisms, such as those of the subtilis group, and for that reason he thinks that the determination of catalase may be made of value in judging the quality of milk, especially for infant feeding.

Biological and biochemical studies of milk. VI, Colostrum, C. J. KONING (*Pharm. Weekbl., 1907; abs. in Rev. Gén. Lait, 6 (1907), No. 12, pp. 282–285*).—According to the author's conclusions colostrum is at first very rich in catalase and diastase and poor in reductase. The percentages of albumin, solids-not-fat, and ash are at first high and the fat and sugar low. The colostral period for the cow ought to be placed at 3 weeks. Just before the end of the lactation period the milk becomes abnormal, a notable feature being an increase in the diastase, catalase, and reductase. In both colostrum and fresh milk the content of catalase and reductase is independent of the action of bacteria.

From studies of human milk and of the colostrum and milk of goats, sheep, and other animals the author concludes that it is not possible to prepare a milk for infants which shall possess the biochemical properties of human milk.

Some diastases of milk, A. MONVOISIN (*Rev. Gén. Lait, 6 (1907), No. 12, pp. 265–272*).—The author has studied the effect of oxygen upon the reductase in milk. This enzym was found to be reduced in amount but not destroyed by the treatment of milk with hydrogen peroxid for the purpose of sterilizing it. The use of formaldehyde with methylene blue as a test for reductase was found more delicate than the use of ethyl aldehyde or methyl aldehyde.

The acidity of milk, its relation to coagulation by heat and alcohol, its determination and its course during souring, I and II, T. HENKEL (*Milchw. Zentbl., 3 (1907), Nos. 8, pp. 340–369; 9, pp. 378–405*).—The acidity of fresh milk varied in 10,000 determinations from 5.5 to 9° (cubic centimeters of N/4 sodium hydroxid solution required to neutralize 100 cc. of milk). The variations in the mixed milk of a herd were between 6.8 and 7.5°. The variations between the morning and evening milk were very small. The acidity of the first and last portions of a milking was generally the same. Occasionally there were marked differences in the acidity of the milk from the different quarters. In general there was a slight decrease in the acidity of milk during the course of lactation. The acidity of colostrum was very high, in one instance 23.6°. The acidity was not affected by sexual heat but was by diseased conditions. No marked influence could be attributed to changes in rations fed.

Fresh milk was not coagulated in any instance by the use of 68 to 70 per cent of alcohol in the ordinary amount. Samples of milk coagulating with alcohol under identical conditions often showed marked differences in acidity.

The milk and cream supply of cities, J. MOLDENHAWER (*Salem, N. Y.: Author, [1907], pp. 80, figs. 10*).—In this little book the author discusses in a popular manner a great many topics bearing upon the improvement of city milk supplies and makes many suggestions based upon his own experience. The pasteurization of milk is especially urged.

Municipal regulation of the milk supply, G. W. GOLER (*Jour. Amer. Med. Assoc., 49 (1907), No. 13, pp. 1077–1079*).—The author outlines what city ordinances should require in regard to milk supplies and discusses the means of enforcing them.

Sanitary milk production (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 114, pp. 38*).—This is a report of a conference appointed by the Commissioners of the District of Columbia to consider and report upon the local milk supply, to advise what steps should be taken to improve it, and to suggest legislation to that end.

The conference recommends that 3 grades of milk be recognized by law, namely, certified milk, inspected milk, and pasteurized milk. These terms are clearly defined. Numerous recommendations are made with a view to securing a better supervision of the milk supply of the District and suggestions are made concerning the duties of consumers.

The following papers are included in the report: Diseases and Conditions of Cattle that may Affect the Quality of the Milk, by J. R. Mohler; Milk Sediments or Dirty Milk in Relation to Disease, by G. M. Kober; Sanitary Inspection of Dairies and Distributing Depots, by E. H. Webster; The Water Supply of Dairy Farms, by G. L. Magruder; Milk during Transportation, by E. Berliner; Commercial Classes of Milk, by A. D. Melvin; and Pasteurization, by M. J. Rosenau.

Several committee reports are also included.

The milk supply of Washington, D. C., G. L. MAGRUDER (*Jour. Amer. Med. Assoc., 49 (1907), No. 13, pp. 1088, 1089*).—A brief statement relating to the studies being made of the milk supply of Washington.

Boston's campaign for clean milk, J. O. JORDAN (*Jour. Amer. Med. Assoc., 49 (1907), No. 13, pp. 1082–1087, figs. 2*).—In 1904 the board of health of Boston adopted milk regulations prohibiting the sale of milk having more than 500,000 bacteria per cubic centimeter or a temperature above 50° F. Of the samples examined during 1905, 87.6 per cent conformed to the bacteriological standard, and of those examined during 1906, 89.98 per cent. The percentage of infected samples as indicated by the presence of streptococci or pus was 10.48 per cent in 1905 and 4.9 per cent in 1906. The article gives much data concerning the work done, and shows that a decided improvement of the city milk supply has resulted from the vigorous efforts made by the board of health.

The methods of dealing with the milk supply of New York City, T. DARLINGTON (*Jour. Amer. Med. Assoc., 49 (1907), No. 13, pp. 1079–1082*).—An outline of the methods employed by the board of health in regulating the milk supply of New York City.

The quality of Danish milk sold in Berlin, B. PROSKAUER, E. SELIGMANN, and F. CRONER (*Ztschr. Hyg. u. Infektionskrank., 57 (1907), No. 2, pp. 173–247*).—Chemical and biological examinations were made of 13 samples of winter milk from Denmark and 8 samples of summer milk.

The specific gravity of the summer milk averaged 1.032 and of the winter milk 1.033. The fat content averaged, respectively, 3.04 and 3.20 per cent. The bacterial content of the summer milk was about 5,000,000 per cubic centimeter and of the winter milk about 2,100,000. This was much higher than Berlin market milk. The catalyzing power of the Danish milk was much lower than that of the Berlin milk. Coagulation with alcohol and on heating occurred earlier with Danish than with Berlin milk. On the whole, the Danish milk was superior to Berlin market milk as regards composition, but inferior as regards biological properties.

Dairy department, W. J. ELLIOTT (*Montana Sta. Rpt. 1906, pp. 168–180, figs. 3*).—In experiments with cream kept for various periods up to 4 days before churning it was found that the churnability of the cream was not affected by the lengths of time the cream was kept. There was some difference in melting point between the butter fat from the fresh cream and that from the older cream, but in all cases the melting point was higher 2 weeks after the butter was made than while it was fresh; then it decreased on keeping for 6 or 8 weeks.

As a result of experiments it was found that with the same separator and the same cows the percentage of fat in the cream may vary more or less from day to day in accordance with differences in the following factors: (1) Temperature of milk separated; (2) high or low speed of separator crank, or speed of separator bowl; (3) rate of inflow of milk; (4) milk of varying butter fat content; (5) amount of skim milk or water used to flush the bowl; (6) acidity of the milk separated, and (7) irregular speed of separator.

A study of the bacterial content of cream, L. L. LEWIS and W. R. WRIGHT (*Oklahoma Sta. Bul. 75, pp. 16, charts 13*).—Bacteriological examinations were made of cream as delivered by patrons of the college creamery during July and August, and again during December, January, and February.

The cream delivered in summer at an age of 3.3 days contained on an average 462,600,000 bacteria per cubic centimeter, and that delivered in winter at an age of 5 days contained 134,800,000. The bacterial content was found to increase for the first 3 days in summer and 4 days in winter, after which there was a steady decrease. More than 50 per cent of the cream delivered during the summer months contained an excessive number of gas-producing bacteria. The digesting bacteria were also present in large numbers. The average cream more than 2 days old in summer could not be handled at the creamery with good results. Rich cream contained less acid than this cream.

The practical use of starters, L. D. BUSHNELL and W. R. WRIGHT (*Michigan Sta. Bul. 246, pp. 139–151, figs. 7*).—A practical method of using starters is described in a popular manner in this bulletin.

Quart bottles of milk are plugged with cotton and sterilized by steam. One bottle is inoculated with a pure culture of lactic-acid bacteria, and after a transfer has been made from this on the second day it is used for inoculating a large can of recently pasteurized milk which may be used the next day as a starter.

The advantages of the method are stated by F. O. Foster as follows:

"The method of carrying motner starters in sterilized milk in glass jars has been given a thorough trial in practical work in the college creamery in comparison with the method commonly employed, which is to inoculate a starter each day from the one prepared the preceding day. The new method has the following advantages:

"The starter can be kept pure for a much longer period, thus saving one-half or more of the cost of pure cultures.

"The milk is always ready for inoculation and the mother starter can be transferred each day when in the best condition and kept vigorous.

"In case a starter is not needed every day, the mother starter can be carried along conveniently without the trouble of sterilizing milk.

"After a thorough trial we have adopted the method for our daily use. We find it no great task to sterilize the bottles of milk once or twice a month, and the little extra labor thus occasioned is more than offset by the convenience and sureness of the new method."

Butter making on the farm, G. H. BARR (*Canada Dept. Agr., Branch Dairy and Cold Storage Comr. Bul. 17, pp. 13, figs. 11*).—This is a popular bulletin on farm butter making. The principal suggestions made are summarized in the following statements: (1) Keep good cows, (2) feed them liberally, (3) keep them comfortable and clean when in the stable, (4) skim a rich cream, (5) keep the cream cool, (6) churn at the temperature that will give a flaky granule in the butter, (7) use clean, pure water for washing butter, not more than 3° colder or warmer than the buttermilk, (8) put the butter up in neat, clean, attractive packages, and (9) keep everything in and about the dairy clean and attractive.

Mottled butter, L. MARCAS and C. HUYGE (*Bul. Agr. [Brussels], 23 (1907), No. 7, pp. 486–491*).—Experiments are reported from the results of which the authors conclude that mottles in butter are due to the presence of buttermilk in conjunction with an uneven distribution of salt. In mottled portions of butter the authors found regularly more casein and less salt than in nonmottled portions of the same lot. The mottling is, therefore, considered due to the action of salt on casein.

Regulations prescribed in regard to renovated butter in accordance with the act of Congress approved May 9, 1902 (*U. S. Dept. Agr., Bur. Anim. Indus. Order 147, pp. 8*).—A pamphlet issued jointly by the Secretary of the Treasury and the Secretary of Agriculture, giving 30 regulations under which "renovated" or "process" butter may be manufactured and marketed. These regulations, which became effective August 15, 1907, supersede all previous regulations pertaining to the same subject.

The practice of soft cheese making, C. W. WALKER-TISDALE and T. R. ROBINSON (*London, 1903, pp. IV+51, figs. 9*).—This is a brief popular outline of essential points in the production and handling of milk, the preparation and marketing of cream, and the manufacture of several varieties of soft cheese, including cream, Gervais, Bondon, Coulommier, Cambridge or York, Pont l'Evêque, and Camembert.

Note on rennet and its preparation, O. JENSEN (*Rev. Gén. Lait, 6 (1907), No. 12, pp. 272-281*).—The rennet preparation which has given the best results in the author's experience in Emmenthal cheese making is made by extracting the calves' stomach with dilute lactic acid. The extract is then inoculated with a vigorous culture of lactic-acid organisms and used within 2 or 3 days. Very great importance, in the opinion of the author, should be attached to the preparation of the rennet extract.

Officials, associations, commissions, and educational institutions connected with the dairy interests of the United States for the year 1907 (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 115, pp. 22*).

The preparation of vinegar from Kieffer pears, H. C. GORE (*Jour. Amer. Chem. Soc., 29 (1907), No. 5, pp. 759-764, dgm. 1*).—The juices of Kieffer pears at ordinary market ripeness, according to the author's investigations, "are so low in sugar that it is impossible to produce from them a vinegar of standard strength (4 per cent acetic acid). The juices of very ripe Kieffer pears probably do contain sufficient sugar to produce a standard vinegar, providing methods of fermentation are employed which will give the maximum yield of acetic acid from the sugar present.

"The method of fermentation of the juice into vinegar which will give the maximum of acetic acid consists in the production of the maximum of alcohol from the sugar by dominant fermentation with selected yeasts, followed by the conversion of the alcoholic liquor into vinegar by the quick process of vinegar making.

"The vinegar obtained is of excellent quality. Its composition is similar to that of cider vinegar, save for its high content of solids and content of pentosans."

Chemical methods for utilizing wood, F. P. VEITCH (*U. S. Dept. Agr., Bur. Chem. Circ. 36, pp. 47, figs. 16*).—This bulletin has been prepared to satisfy "the demand for information as to the nature and uses of the chemical compounds manufactured from wood and the processes and equipment used in their production," especially with reference to the disposition of waste material. Attention is given particularly to the destructive distillation of wood, the recovery of turpentine, rosin, and paper pulp, the preparation of alcohols, and the manufacture of acids. An attempt has been made to explain the processes as simply as the subject-matter will permit.

VETERINARY MEDICINE.

Handbook of comparative microscopic anatomy of domesticated animals, W. ELLENBERGER (*Handbuch der Vergleichenden Mikroskopischen Anatomie der Haustiere. Berlin, 1906, vol. 1, pp. VIII+601, figs. 437*).—The present volume is an outgrowth of the work published under the same editorship in 1887, under the title "Histology of Domestic Mammals." The histological anatomy of man has been very thoroughly worked out and presented in convenient form for reference. Reliable descriptions of microscopic anatomy of domestic animals, however, had not been sufficiently available.

The present volume contains an elaborate account of the microscopic anatomy of all domesticated animals from a comparative standpoint. The material is arranged according to the kind of tissues concerned and has been prepared by various specialists. Abundant bibliographical references are given throughout the text.

Results of investigations in the field of general pathology and pathological anatomy, O. LUBARSCH and R. OSTERTAG (*Ergeb. Allg. Path. Mensch. u. Tiere, 11 (1906), pt. 1, pp. XIV+1-1053, pls. 5, figs. 18*).—An extensive summary is given of the recent literature relating to diphtheria, syphilis, pathogenic molds, protozoan diseases of animals, hemolysins, and theories of immunity. A large part of the volume is occupied with a discussion of immunity and protozoan diseases of animals. The literature on the older theories of immunity is given less attention than that relating to the recent theories of immunity as based on opsonins, and bacteriotropins.

Progress in the study of immunity and the specific nature of bacteria since 1870, with particular reference to tubercle bacilli, R. P. VAN CALCAR (*Prog. Bot., 1 (1907), No. 3, pp. 533-644, figs. 20*).—A detailed critical review is given of the literature relating to theories of immunity and the classification of bacteria in connection with a classified bibliography. Particular attention is given to the developmental forms of the tubercle bacillus and other acid-fast bacilli.

Course of instruction in the Kazan veterinary institute (*Uchen. Zap. Kazan. Vet. Inst., 24 (1907), No. 2-3, pp. 77-154*).—A detailed outline is given of the course of instruction offered at the Kazan veterinary institute. The subjects covered by the course include dissection, physiology, histology, stock judging, stock breeding, farm hygiene, feeding of animals, general and special pathology, pharmacology, general and special therapeutics, bacteriology, veterinary surgery, and clinics.

Report of the chief of the cattle bureau, Massachusetts (*Semiann. Rpt. Cattle Bur. Mass., 10 (1906), pp. 215-279*).—During 1906, rabies continued to prevail to an unusual extent. Nearly 600 dogs were killed on account of being infected with the disease, and a number of other animals also became infected through dog bites. Attention is called to the difficulty of regulating this disease satisfactorily on account of the long period of incubation.

Glanders appears to be somewhat on the decrease as compared with the year previous to this report. The work of inspection for glanders is presented in a tabular form.

An account is also given of the work of the cattle bureau in the control and eradication of tuberculosis. The financial statement accompanying the report indicates the amounts paid as indemnity for various diseased animals.

[Veterinary work] (*Oklahoma Sta. Rpt. 1906, pp. 38-41*).—Since 1900, the station has distributed more than 625,000 doses of blackleg vaccine. Brief directions are given for the use of this vaccine.

Canker of pigs is due to a mange mite. The disease may be treated with carbolic acid, iodin, or a solution of tobacco.

Intestinal parasites in hogs may be expelled by the use of a mixture of spigelia and senna, wormseed, cedar apples, areca nut, or turpentine. Two teaspoonsful of turpentine may be given in milk twice daily.

Conditions which render the mucous lining of the digestive tract permeable to bacteria, J. Bassett and H. Carré (*Compt. Rend. Soc. Biol.* [*Paris*], *62* (*1907*), *No. 17, pp. 890, 891*).—The experiments reported in this paper were carried out on 20 dogs, which were given doses of podophyllin in order to cause irritation of the digestive mucosa.

In 18 of the 20 dogs positive identification was made of intestinal bacteria in the blood of the portal vein, in the chyle, or in both. The bacteria were cocci, staphylococci, and streptococci, such as are found in the intestines of normal dogs. It appears, therefore, that any irritation such as is set up by the use of podophyllin is sufficient to render the alimentary tract permeable to ordinary intestinal bacteria.

A preliminary note on neutral red reaction in the infected red cells of protozoal diseases, F. S. H. Baldrey and W. A. Mitchell (*Jour. Trop. Vet. Sci.*, *2* (*1907*), *No. 2, pp. 169–171, pl. 1*).—In the use of neutral red an excellent means has been found for demonstrating protozoa in blood corpuscles after the digestive action set up in such cases has led to the production of an acid cytase. The method may be used successfully both in cases of red blood corpuscles, the substance of which is being digested by parasitic protozoa, and in white blood corpuscles which are digesting enclosed protozoa. Illustrations are given of the results of applying this method in a study of *Piroplasma canis*.

The effect of glycerin upon tuberculous lesions, V. Galtier (*Jour. Méd. Vét. et Zootech.*, *58* (*1907*), *May, pp. 263–266*).—Tuberculous organs, including lungs, livers, spleens, etc., when completely submerged in glycerin for periods of 8 to 18 months become entirely sterile. An immersion of 7 months is usually sufficient to destroy the virulence of tubercle bacilli. The bacilli are gradually attenuated, as shown by inoculation experiments made with them after they had been kept in glycerin for a few days.

Bovine tuberculosis, L. Van Es (*North Dakota Sta. Bul. 77, pp. 379–430, pls. 11*).—A discussion is presented of tuberculosis in its varied relations to animal industry and human health. Particular attention is given to bovine tuberculosis, including its lesions, prevalence, distribution in the body, cause, symptoms, and diagnosis, the tuberculin test, the economic importance of tuberculosis, and the methods of eradication. A brief bibliography of tuberculosis is also given.

Tuberculosis in swine, W. J. Kennedy et al. (*Iowa Sta. Bul. 92, pp. 24, figs. 2*).—The experiments recorded in this bulletin were undertaken for the purpose of determining the effect of feeding pigs skim milk containing tubercle bacilli, as compared with pasteurized skim milk. The pigs used in the experiments numbered 40 and were divided into 4 equal lots. Two lots received pasteurized milk, one on pasture and the other in a dry yard. The other 2 lots received tuberculous milk, one on pasture and the other in a dry yard. All of the pigs which were fed tuberculous milk became infected and also 2 of the pigs which received pasteurized milk.

It appears that tuberculosis is not readily spread among pigs by mere proximity of diseased to healthy animals. The authors conclude that tuberculous milk is almost sure to infect pigs, while milk pasteurized at a temperature of 200° F. is a safe feed. Pigs confined in clean dry yards are apparently no more susceptible to tuberculosis than those which are kept at pasture.

Tuberculosis in swine, L. E. CARTER (*Iowa Sta. Bul. 92, popular ed., pp. 11*).—A popular edition of the above.

The use of Röntgen rays in the inspection of tuberculous meat, H. MARTE (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 23, pp. 1298–1300*).—The tuberculous lesions of pork and beef commonly contain deposits of lime salts. It was suggested to the author to test the possible value of X-rays in the identification of tubercles, particularly in lymphatic glands so situated that their examination by the ordinary methods would necessitate so cutting the meat as to depreciate its market value. It was found that the shadows obtained from the use of X-rays were very different in the case of tuberculous glands from those of glands surrounded by large quantities of fat. While dense masses of fat produce a shadow, the shadow is uniform rather than granular, as is the case when lime salts are deposited.

Anthrax, W. C. PATRICK (*Jour. Roy. Inst. Pub. Health, 15 (1907), No. 5, pp. 279–285.*)—The symptoms and post-mortem lesions of this disease are briefly described. Attention is called to its prevalence in the various parts of Great Britain and to its occurrence in man. It is suggested that on account of the imperfect system of meat inspection in England, except in large cities, it is possible for the meat of the animals affected with anthrax to be offered for sale in public markets.

The filterability of hog cholera bacilli, L. F. D. E. LOURENS (*Centbl. Bakt. [etc.], 1. Abt., Orig., 44 (1907), Nos. 5, pp. 420–427; 6, pp. 504–512; 7, pp. 630–648, figs. 5*).—An elaborate review is given of the results obtained by different investigators in the study of the biology and pathogenic properties of the hog cholera bacillus. Recently an unusual interest has been added to this study by reason of the discovery by the Bureau of Animal Industry of this Department that hog cholera may be produced by inoculating susceptible animals with filtrates from infected organs and from pure cultures of the hog cholera bacillus. These results have been confirmed by a number of investigators in other countries. In fact in South Africa, A. Theiler was unable to find the hog cholera bacillus in the form of the disease which prevails in that country.

At the beginning of his investigations the author suspected that aggressins might be present in the filtrates from infected organs and cultures of hog cholera bacilli, which render the animals so susceptible to the disease that the slightest infection with the hog cholera bacillus would produce the symptoms of the disease, while without the influence of aggressins no infection would have taken place. To this end material obtained from the organs of hogs affected with chronic or acute hog cholera was passed through various filters including the Chamberland, Berkefeld, and Kitasato forms. In inoculation experiments with this material the results were sometimes positive and sometimes negative. Further experiments were then carried on to determine whether the hog cholera bacilli could themselves pass through the filters. It was found that hog cholera could be produced in hogs as a result of inoculation with filtrates which were apparently free from bacteria at the time of inoculation and that subsequently hog cholera bacilli appeared in these animals.

A number of other experiments were carried on with filtrates from pure cultures of hog cholera bacilli and positive infections were produced. In the author's opinion the hog cholera bacillus may pass through the Chamberland, Berkefeld, or Pukall filter. The extent to which such passage through filters takes place depends largely upon the treatment of the filters and the fluid in which the filtrate is diluted.

The explanation of the passage of hog cholera bacilli through filters previously shown to be too fine for the passage of bacteria of normal size is believed to be found in the granulation of these bacilli, as repeatedly observed by the author. The bacilli appear to exist at times in the form of granules, which may be regarded as the resting stage of the bacillus. These granules appear like cocci, and the single bacillus may become divided into as many as three of them. The granules are highly refractile and appear at first at either end of the bacillus, where they might be mistaken for spores. It is apparent, therefore, that the extent to which bacilli pass through filters depends largely on the degree of granular disintegration of the bacilli. In a too highly diluted serum they failed to pass through the filters.

A similar granulation and passage through filters was observed in the case of *Staphylococcus aureus*, *S. albus*, the typhoid bacillus, blackleg bacillus, and *Bacillus enteritidis*.

As a result of these experiments, the author comes to the following conclusions: The hog cholera bacillus under certain conditions may pass through unvitrified porcelain filters. Its power of passing through filters depends upon its property of dividing up into granules, which in turn is considered as a natural peculiarity of the hog cholera bacillus. In all cases of true hog cholera, *Bacillus suipestifer* may be demonstrated, and this is considered as the only cause of the disease.

The nature of Spirochæta, G. MAROTEL (*Jour. Méd. Vét. et Zootech., 58 (1907), May, pp. 294–306, figs. 4*).—A list is given of the species of Spirochæta which are known to produce disease in man, chickens, dogs, cattle, sheep, horses, etc. At first no doubt was entertained that these organisms belonged with the bacteria. Later, evidence was presented in favor of grouping them with the protozoa. The facts for and against such a classification are presented by the author, who comes to the conclusion that the affinities of Spirochæta have not been definitely determined, but in the case of most species the evidence is rather in favor of their being bacteria.

Immunity in spirochæte septicemia of fowls and the question of the classification of Spirochæta with protozoa, F. NEUFELD and VON PROWAZEK (*Arb. K. Gsndhtsamt., 25 (1907), No. 2, pp. 494–504, fig. 1*).—The serum of fowls which have recovered from septicemia due to infection with Spirochæta possesses, in vitro at least, a very strong immunizing effect, but this power varies to a striking extent. The authors' study of the Spirochæta found in cases of fowl septicemia has led them to the opinion that these organisms are more closely related to the protozoa than to bacteria.

The treatment of tsetse-fly disease with brilliant-green, WENDELSTADT (*Sitzber. Naturhist. Ver. Preuss. Rheinlande u. Westfalens, 1906, I, pt. B, pp. 4–7*).—Previous experiments in the use of trypanrot and other substances for the destruction of the trypanosomes of tsetse-fly disease have shown that these organisms may temporarily disappear in the blood as the result of curative injections, but that they subsequently reappear. Similar results were had with brilliant-green. The trypanosomes, even in bad cases of infection in rats, entirely disappeared within 24 to 36 hours after a subcutaneous injection of 1 cc. of an aqueous solution of brilliant-green, but within a few days, however, they reappeared. It was found that subsequent injections would cause them to disappear again, but it is not safe to repeat the injections of brilliant-green indefinitely for the reason that it causes necrosis of the tissues. In 1 rat and also in 1 ape a complete cure was brought about.

Transmission of yaws by ticks, E. E. MODDER (*Jour. Trop. Med. and Hyg. [London], 10 (1907), No. 11, p. 187*).—A disease known as yaws has been observed by the author in fowls, cattle, and man. Some evidence is presented in favor of the belief that the disease is transmitted by ticks belonging to the species *Ixodes bovis*.

The action of tetanus bacilli and their toxins upon the alimentary tract, M. RABINOWITCH (*Arch. Hyg., 61 (1907), No. 2, pp. 103–150*).—In experiments with laboratory animals it is found that the gastric juice under normal conditions destroys the virulence of tetanus bacilli and tetanus toxin, the latter being affected more promptly. This action of the gastric juice is more efficient the higher its content of common salt. A 1 per cent solution of normal hydrochloric acid will destroy the virulence of tetanus bacilli within 2 hours at a temperature of 37° C.

When tetanus bacilli are fed to rabbits and guinea pigs in large doses they do not produce symptoms of tetanus, but the animals may be affected by a progressive marasmus which sometimes terminates fatally. In rabbits the introduction of tetanus toxin into the stomach sometimes causes peculiar cerebral symptoms. The presence of tetanus bacilli and tetanus toxin in the stomach of animals may, therefore, be dangerous or even fatal, notwithstanding the fact that the gastric juice exercises a vigorous action upon them.

Infectious granular vaginitis of cattle; its treatment and prophylaxis, H. RAEBIGER (*Rev. Gén. Méd. Vét., 9 (1907), No. 107, pp. 625–635; 108, pp. 689–697*).—The continued prevalence of infectious granular vaginitis has rendered necessary certain quarantine and therapeutic regulations in order to control the disease. It is recommended that no cow be introduced into a herd without first subjecting her to a veterinary inspection for the possible presence of the disease. In order to insure the further safety in herds where an outbreak of the disease has occurred, it is recommended that all bulls and cows should receive proper antiseptic treatment.

Vaccination against rinderpest by the combination method in 1906, V. TVARYANOVICH (*Arch. Vet. Nauk [St. Petersb.], 37 (1907), No. 3, pp. 211–225*).—During the maintenance of quarantine for rinderpest, vaccination experiments were made on a number of bulls, cows, and calves, using the combination method of serum and virulent blood. The results obtained were very satisfactory. It appeared that the method not only has a vaccinating effect, but also exercises a curative effect in a certain percentage of cases.

Ticks and tick fever conference (*Queensland Agr. Jour., 18 (1907), No. 6, pp. 281–320*).—A conference was held in Brisbane on May 7, 1907, at which many representatives of scientific and agricultural organizations were present for the purpose of discussing the status of Texas fever and the means for combating it. It appears that the history of the disease in Queensland has been very similar to that of its progress in the United States.

The dip recommended for freeing cattle of ticks contains 8 lbs. of arsenic, 4 lbs. of caustic soda, 1 gal. of Stockholm tar, and 8 lbs. of tallow in 400 gals. of water. Various modifications of this dip have also been tested. The problems connected with the prevalence of Texas fever in Queensland are discussed from various standpoints by C. J. Pound, R. S. Archer, C. J. Booker, S. Kelly, and others. A resolution was adopted recommending compulsory dipping of cattle in all tick-infested districts. It was also urged that a government subsidy be granted to private dipping plants provided these are open to the public.

A note on a new species of trypanosoma discovered in the blood of an Indian bullock at Singapore, P. S. FALSHAW and A. LINGARD (*Jour. Trop. Vet. Sci., 2 (1907), No. 2, pp. 217–220, pl. 1*).—A zebu affected with a chronic disease accompanied with fever was examined by the authors after the animal had died from the disease. The blood obtained from the diseased animal was inoculated into dogs without obtaining any infection. An examination of the blood showed the presence of a very large trypanosome, parasites of Texas fever, and a number of other protozoan organisms. A description is given of the large species of trypanosome found, but no descriptive name is used.

Strongylus contortus and blue tongue, A. Grist (*Orange River Colony, Dept. Agr., Vet. Div. Leaflet 4, pp. 17*).—The life history of *Strongylus contortus* is briefly outlined. In combating this pest attention should be given to the quality of the drinking water and the condition of pastures. Some benefit is derived from the administration of a solution of copper sulphate or arsenic to infested sheep.

Blue tongue of sheep appears to be a catarrhal fever which affects the mucous membrane of the mouth and other parts of the alimentary tract. The period of incubation is 2 to 5 days. An attempt is being made to produce a vaccine for the prevention of blue tongue.

Infectious inflammation of the spinal cord, or azoturia, M. Schlegel (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 2 (1907), No. 6, pp. 459–545, pls. 3*).—In a long continued study of various cases of disease in horses, known as inflammation of the spinal cord, meningo-myelitis, infectious paralysis, hemoglobinemia, hemoglobinuria, azoturia, and black ischuria, the author has accumulated conclusive evidence that these are merely names of one and the same disease, which is of an infectious nature, due to *Streptococcus melanogenes*, discovered by the author in 1906. This organism occurs as a regular saprophyte in the intestines of healthy horses and often in cases of diseases. Under especially favorable conditions it may become highly virulent, gain entrance to the blood, and produce the symptoms which are characteristic of infectious spinal paralysis or azoturia.

The pathological lesions which are noted in cases of this disease include a black tarry condition of the blood which does not coagulate regularly, pronounced disintegration of the blood corpuscles, transformation of the hemoglobin into melanin, and also various alterations in the structure and composition of the liver, kidneys, bones, and other tissues.

The pathogenic organism of the disease has been isolated and studied from pure cultures in various nutrient media.

In combating this disease according to the new conceptions furnished by the author's investigations, it is desirable to isolate affected horses and to disinfect all excretions, since the organism of the disease may be carried in them.

Recovery from glanders, Mouilleron (*Bul. Soc. Cent. Méd. Vét., 84 (1907), No. 10, pp. 223–230*).—The repeated application of the mallein test to a glandered horse gave a gradually diminishing reaction, and during the last 4 years of his life no reaction took place. The horse was under continuous observation for 8 years. At the end of this time the animal was killed and carefully examined. All organs were perfectly healthy and entirely or nearly without the evidence of previous lesions.

The etiology of pneumonia, Lorenz (*Berlin. Tierärztl. Wchnschr., 1907, Nos. 23, pp. 447–450; 24, pp. 471–474, pls. 2*).—In a study of the micro-organisms found in cases of this disease the author finds undoubted evidence of transformation stages from streptococci to branched threads of streptothrix, and under certain conditions a retransformation of these threads into streptococci. The streptothrix threads with numerous branchings appear most regularly when the original streptococci are inoculated into pure cultures of Aspergillus. When these cultures in turn are inoculated into ordinary nutrient media, the streptococci reappear. The author considers that the appearance of branched threads of streptothrix in the lungs and skin of horses affected with the disease is undoubted evidence of the causal connection of this organism with pneumonia.

Preliminary note on a parasite found in connection with "the irritable summer skin disease" of horses in India, V. B. Nesfield (*Jour. Trop. Vet. Sci., 2 (1907), No. 2, pp. 172–176, fig. 1*).—In various parts of India a quite serious skin disease of horses has been observed which is confined strictly to horses of Australian origin. The disease occurs only in hot and rainy weather and disappears entirely in cold weather. The hair breaks off leaving bald scaly patches somewhat like those which occur in ringworm. An examination of the hair on diseased areas revealed the presence of large numbers of minute highly refractive bodies in the substance of the hair. These bodies resist the solvent action of hot caustic potash and stain readily with basic anilin dyes.

The nervous form of distemper in dogs, Ohler (*Wchnschr. Tierheilk. u. Viehzucht, 51 (1907), No. 21, pp. 401–404*).—For many years text-books have contained descriptions of the symptoms of nervous distemper in dogs in which nervousness appears in advance of any other lesions or symptoms which characterize distemper. According to the author's investigations the term nervous distemper is perhaps a misnomer. In no instance was he able to observe any nervous condition in advance of other symptoms of distemper and connected with this disease. In all cases in which pronounced nervousness, comparable with the symptoms so described for nervous distemper, occurred, it was more easily explained as due to other causes.

The diagnosis of rabies from the standpoint of veterinary police work, Lübke (*Berlin. Tierärztl. Wchnschr., 1907, No. 21, pp. 415–420*).—Statistics are given regarding the prevalence of rabies in various parts of Europe with particular reference to some of the more serious outbreaks of the disease. Even during the progress of these serious outbreaks, but particularly at times when the disease occurs only sporadically, there are many individuals who doubt the existence of the so-called dumb form of the disease and, therefore, give protection to affected dogs which are largely responsible for the spread of the disease. A number of instances are mentioned in which such dogs have occasioned the wide distribution of rabies.

Negri corpuscles and their relation to rabies, V. Babes (*Ztschr. Hyg. u. Infektionskrank., 56 (1907), No. 3, pp. 435–452, pls. 2*).—On the basis of his experiments with rabies the author comes to the conclusion that certain minute corpuscles, which appear in cases of rabies and which may be stained black or blue by the method of Cajal-Giemsa and are exclusively found in the cytoplasm of disintegrated nerve cells, are the parasitic organisms of rabies in an active condition. Negri corpuscles, on the other hand, are not always present and are evidently not closely enough associated with the progress of rabies to be considered the active cause of the disease. They appear to be encapsulated forms of the rabies organism in a process of involution or transformation. Possibly they are the result of an intense local reaction of the tissues against the presence of the rabies parasites.

Negri corpuscles in the salivary glands of rabid dogs, Elise Stefanescu (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 17, pp. 886–888*).—A considerable number of investigators have already demonstrated the presence of Negri bodies in different parts of the nervous system. On account of the extreme virulence of the saliva of rabid animals the author made a study of the salivary glands in order to determine whether Negri corpuscles occurred in these structures. Negri bodies were found in the parotid glands. In demonstrating these bodies the author fixed small pieces of tissue in formaldehyde and sectioned them upon the freezing microtome.

Spontaneous recovery of dogs from rabies and the persistence of the virus in the saliva, P. Remlinger (*Bul. Soc. Cent. Méd. Vét., 84 (1907), No. 10, pp. 269–275*).—It has long been known that rabid dogs and other animals may recover from the disease. It has been believed, however, that the virus is not virulent after recovery. The author cites a case in which the virus was extremely virulent for some time after recovery from the disease.

Antirabies serum, P. Remlinger (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 18, pp. 961–963*).—The activity of serum is not proportional to the quantity of virus injected into the animal used for the production of the serum. In one instance a sheep which had received hypodermically 130 rabbit brains furnished a less active serum than another sheep which had received only 81. Quite often rapid and unexplained changes take place in the activity of the serum of animals used for experimental purposes. This matter has not yet received satisfactory explanation.

Leukemia of the common fowl, A. S. Warthin (*Jour. Infect. Diseases, 4 (1907), No. 3, pp. 369–381, pl. 1, figs. 8*).—Brief mention is made of the cases which have previously been reported of leukemia in domesticated animals. The outbreak studied by Moore (E. S. R., 9, p. 890) and referred to under the name infectious leukemia is believed by the author not to be leukemia but a leucocytosis due to some bacterial infection.

The author has had opportunity to study two forms of lymphocytoma which are referred to as aleukemic and leukemic. In the aleukemic form of lymphocytoma no increase in the number of white cells is observed in the blood vessels. In the leukemic form of the disease the ratio of the red cells to the white in the blood may be less than 2 : 1 and a differential count of the white cells shows that on an average 84.5 per cent are large lymphocytes. In normal hens' blood the proportion of red blood corpuscles to white is 105–225 : 1 and only 14 per cent of the white cells are large lymphocytes. The tissue changes which occur in leukemic lymphocytoma consist in tumorous nodules and infiltration of lymphoid cells in liver, spleen, bone marrow, and other organs. The normal white cells of the blood are replaced by large lymphocytes and a secondary degeneration of the organs takes place.

The action of atoxyl on spirillosis of fowls, C. Levaditi and J. McIntosh (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 21, pp. 1090–1092*).—When atoxyl is mixed with the virus of spirillosis in vitro, it does not exercise a very pronounced effect upon the virus. In living fowls, however, atoxyl causes regressive alterations in the spirilla of the disease. The specific effect of atoxyl seems to be an exaggeration of the means normally employed by the organism in self-defense.

Immunization against fowl cholera with bacterial extracts, E. Weil (*Ztschr. Hyg. u. Infektionskrank., 56 (1907), No. 3, pp. 509–515*).—This article is largely of a controversial nature. The author maintains that the action of aggressins and bacterial extracts are by no means the same in the case of fowl cholera.

The value of gaseous disinfectants, L. L. Lewis and Maude English (*Oklahoma Sta. Circ. 6, pp. 8*).—Experiments were made to determine the disinfectant power of sulphur dioxid, vaporized carbolic acid, and formaldehyde gas toward anthrax spores, *Staphylococcus pyogenes aureus*, typhoid bacilli, glanders bacilli, *Bacillus bovisepticus*, etc.

Sulphur fumes have the disadvantage of decolorizing fabrics and attacking metals. They can not be depended upon to disinfect in a dry atmosphere. In a moist atmosphere 5 lbs. of sulphur burned in 1,000 cu. ft. of space will kill anthrax bacilli if allowed to act for 4 hours.

Anthrax spores were not killed by exposure for 6 hours to the fumes of carbolic acid (625 cc. being vaporized in 1,000 cu. ft. of space).

Formaldehyde does not injure fabrics or metals and is most effective. Under ordinary conditions 240 cc. per 1,000 cu. ft. of space will give good results. Notes are given on the use of formaldehyde candles and generators. Formaldehyde does not penetrate fabrics very vigorously. The room should show a temperature of about 98° F. and a moisture content of 90 per cent.

The disinfection of skins infected with anthrax, Xylander (*Arb. K. Gsndhtsamt., 25 (1907), No. 2, pp. 457–477*).—In the practical destruction of anthrax spores on skins in tanneries it is considered necessary that they be treated with formaldehyde for from 6 to 14 days by the addition of 0.5 to 1 per cent of formaldehyde to the liquid in which the skins are kept. This strength of formaldehyde will destroy the anthrax spores, but unfortunately it injures the skins to such an extent that they are not suitable for commercial use thereafter. Formaldehyde is, therefore, not a practical disinfectant for use in this connection. Similarly in using corrosive sublimate, lysol, lysoform, and cresols the objection is found that poisonous effects are experienced by workmen who handle skins treated in this manner, and also that the leather is somewhat injured. The experiments thus far carried on have not led to a practical method for the disinfection of skins.

RURAL ENGINEERING.

Irrigation, J. J. VERNON (*New Mexico Sta. Rpt. 1906, pp. 29–38*).—This report covers the irrigation experiments made at the New Mexico Station in cooperation with this Office during 1905. The experiments included a comparison of cost and results in irrigating with river water and with water pumped from wells. With alfalfa the yields were slightly larger where river water was used, although the cost of producing the alfalfa was but 62 cts. per ton with river water and $4.46 per ton with pumped water. On the other hand, the yield of tomatoes irrigated with well water was three times as large as that from plants irrigated with river water, while the expense was but 50 per cent larger.

Evaporation records were kept, the total evaporation for the year being 58 in., estimating the evaporation for two weeks in July not covered by the records.

Tests were made of four pumping plants, one using a steam engine and three with gasoline engines, in two of which naphtha was used for fuel instead of gasoline. Efficiencies of the engines were remarkably uniform, varying from 71 to 78.54 per cent. The efficiencies for the entire plants are not given. The fuel cost per foot-acre-foot with the steam engine with coal at $5 per ton was 6.89 cts., with gasoline at 19.5 cts., 7.27 cts., and with naphtha at 13.5 cts., 5 cts. for one of the plants, and 17 cts. for the other.

Irrigation investigations, E. NELSON (*Idaho Sta. Bul. 58, pp. 46, figs. 2*).—This bulletin gives the results of irrigation investigations carried on in 1906 in cooperation with this Office. The work was confined to the Twin Falls tract in south central Idaho on the Snake River and included soil-moisture determinations before and after irrigating, in connection with observations on the conditions of the crops to determine the water-holding capacity of the soil, the degree of wetness most conducive to plant growth, and the amount of water which can be applied at a single irrigation without waste.

It was found that the maximum water capacity of the Twin Falls soils was 24.72 per cent by weight and 43.69 per cent by volume, or sufficient to cover the land to a depth of 5.24 in. for each foot of soil. The unbroken soil was found to be moist at a depth of only 18 in. and contained 5.78 in. of water in the first 3 ft. Land irrigated the preceding season contained in the spring 10 in. of water in the first 3 ft. It was found that irrigated land can hold by capillarity 10 in. of water in 3 ft. The average quantity of water used on first-year land was 21.88 in. and on the second-year land 17.84 in., the average amount applied in a single irrigation being 7.84 in.

The furrow system of irrigation is used on 90 per cent of the land in the Twin Falls tract, the furrows being made 20 to 24 in. apart. The cost of clearing land and preparing it for irrigation and for seeding is given as $10.50 per acre. The average yields per acre reported are: Wheat, 45 bu.; oats, 80 bu.; potatoes, 250 bu.; corn, 30 bu.; alfalfa, first year, 1 ton; second year, 6 tons, Seepage measurements were made on the main canal and several of the laterals, the results in average percentage of loss per mile being as follows: Main canal, 1.17 per cent; low line, 1.95 per cent; high line, 1.41 per cent; main laterals, 3.29 per cent; coolies, 0.9 per cent. The natural channels therefore show the smallest loss, and the percentage of loss in the artificial channels increases as the volume of water decreases.

Weir experiments, coefficients, and formulas, R. E. HORTON (*U. S. Geol. Survey, Water-Supply and Irrig. Paper No. 200, pp. 195, pls. 38, figs. 17*).—This is a revision of Paper No. 150 of the same series, the change consisting in the addition of tables giving the discharge over thin-edge weirs by Bazin's formula, and tables giving multipliers for the determination of the discharge over broad-crested weirs, all prepared by E. C. Murphy.

Report on the drainage of the eastern parts of Cass, Traill, Grand Forks, Walsh, and Pembina counties, North Dakota, J. T. STEWART (*U. S. Dept. Agr., Office Expt. Stas. Bul. 189, pp. 71, pls. 6, figs. 2*).—The surveys reported in this bulletin dealt with lands which represent an area of about 3,000,000 acres in the valley of the Red River of the North, which has so little fall that in many years the soil is too wet for crop production.

The surveys were made for the purpose of determining the feasibility of draining the valley, the location and size of drains necessary, and the cost of their construction. The work was done by this Office in cooperation with the State of North Dakota, the counties in which the surveys were made, and the Great Northern Railway Company.

The report deals with the general topographical and climatic conditions and characteristics of streams tributary to Red River, the size, form, and silting of ditches, the erosion of channels, the effect of straightening natural drainage channels, and estimates and recommendations in general and in detail for each separate county represented. It is shown that faulty drainage can, in great measure, be overcome by increasing the efficiency of existing natural water courses, by straightening the channels, removing obstructions, and building levees at low points.

"Where banks of streams are higher than the land a short distance away from them, as is true of nearly all of the streams in the valley, they act as natural levees to hold the streams within their channels and should not be cut to furnish an outlet for a drainage ditch unless it is impossible to secure such outlet in any other way. There are usually coulées and natural channels running parallel to the streams, back of the bank ridge, which finally enter the main stream, into which ditches may be discharged. Wherever it is possible all ditches should enter the streams through these natural channels. It would greatly facilitate drainage movements in the area surveyed if tributary streams were declared drainage channels and placed under the supervision of drainage authorities."

Examination and classification of rocks for road building, including the physical properties of rocks with reference to their mineral composition and structure, E. C. E. LORD (*U. S. Dept. Agr., Office Pub. Roads Bul. 31, pp. 29, pls. 10, fig. 1*).—This bulletin describes in some detail the more important quantitative methods of microscopic rock analysis used in the Office of Public Roads, and reports the results of such examinations, proposes a classification of road material suited to the requirements of road builders and engineers, and discusses the relation of the physical properties of rocks to their mineral composition and structure.

The road-making rocks examined are graded into classes, types, families, and subfamilies or varieties, and the various distinguishing features of each group explained at length.

In the application of the results of these tests to the correlation of the physical properties of the rock families with their mineral components the following conclusions have been reached:

"(1) Igneous and metamorphic rocks, owing to a higher degree of crystallization and a preponderance of silicate minerals, offer a greater resistance to abrasion than nearly all varieties of sedimentary rocks.

"(2) The coarse-grained intrusive rocks of the igneous class are harder, but break more readily under impact than the finer-grained volcanic varieties of like mineral composition.

"(3) The deleterious effect of atmospheric weathering on the wearing qualities of rocks has been demonstrated.

"(4) The cementing value of rocks is, to a certain degree, measured by the abundance of secondary minerals resulting from rock decay.

"(5) Metamorphic rocks have, as a rule, a low binding power, owing to a regeneration of secondary minerals and to the effects of heat and pressure. The foliated types part readily along planes of schistosity, and therefore are not well adapted to road construction.

"(6) The quantitative mineral analysis of rocks serves to a certain extent as a measure of their useful properties for road construction."

The construction of macadam roads, A. B. FLETCHER (*U. S. Dept. Agr., Office Pub. Roads Bul. 29, pp. 56, pls. 6, figs. 10*).—This bulletin describes in some detail the best practice in macadam road construction, and especially that followed by the Massachusetts highway commission.

"It is intended as a brief description and discussion of the several processes and essential features entering into the construction of macadam roads in rural sections. Some data as to costs, especially for the information of road officials who have not undertaken such work, are included.

"The details of construction may require modification to some extent to be suitable for different parts of the country, depending upon amount of rainfall, temperature, and topography, but the general type of road to which this bulletin relates is adaptable to nearly all parts of the United States where suitable stone exists or to which such stone may be carried without excessive cost."

Corn-harvesting machinery, C. J. ZINTHEO (*U. S. Dept. Agr., Farmers' Bul. 303, pp. 32, figs. 20*).—This is a condensation of Bulletin 173 of this Office (E. S. R., 18, p. 785).

Farm buildings, (*Chicago, 1907, rev. ed., pp. 310, pl. 1, figs. 515*).—This is a new and thoroughly revised edition of this book, and consists of "a compilation of plans for general farm barns, cattle barns, dairy barns, horse barns, sheep folds, swine pens, poultry houses, silos, feeding racks, sheds, farm gates, portable fences, etc., all representing construction in actual use."

Ventilation, heating, and lighting, W. H. MAXWELL (*London, 1907, 2. ed., rev. and enl., pp. VI+151; rev. in Nature [London], 76 (1907), No. 1968, p. 268*).—"The simple principles and practice of ventilation, heating, and lighting are described in this volume from the point of view of the sanitary engineer."

RURAL ECONOMICS.

West Virginia agriculture and its possibilities, J. B. GARVIN ET AL. (*Rpt. W. Va. Bd. Agr., 1907, No. 6, pp. 48, figs. 18, maps 4*).—As a means of furnishing information to prospective agricultural settlers, this bulletin describes the topography of the State, including descriptions of its natural and mineral resources, the origin and distribution of its soils, and the crops grown thereon. The live-stock industry of the State is also described.

It is claimed that there are 5,155,532 acres of virgin land, or about 30 per cent of the total area of the State, which are capable of being brought under cultivation. The railroads and industries are said to be drawing the population from the land into the towns and cities by their demand for labor. "Young and middle-aged men have been attracted thither by the inducement of better wages than the farm, managed after the old way, could provide. In some cases the old folks are left to care for the farm as best they can, and such farms as well as virgin lands could be bought for a reasonable sum. With energy and a little capital these lands could be made to produce a comfortable living, provide a home free from the cares and anxieties experienced in the strenuous life in the city." This movement toward the cities centralizes a large nonproducing population which must buy their food supplies, and to meet this demand affords abundant opportunity for the development of agriculture throughout the State.

Agriculture and agricultural services [in Jamaica], J. A. SWETTENHAM (*Colon. Rpts., Ann. [Gt. Brit.], No. 524, pp. 8–23*).—The agricultural conditions of Jamaica in 1905–6 are described, and statistics relating to the exports and imports of products are reported and compared with similar data for preceding years.

There has been a steady improvement in the general agricultural conditions of the colony during the year. The wages of farm laborers range from 1s. to 1s. 6d. per day. The agricultural society reports 498 members in the central organization and 50 branch societies with 2,580 members. Its objects are "to obtain useful information and to disseminate it, to encourage improved cultivation of products and improved breed of stock, and to watch over the agricultural industry generally."

Irish migratory agricultural laborers, 1906, W. G. S. ADAMS (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis., 1906, pp. 42*).—This is a report on the number of agricultural laborers migrating for work to England and Scotland in 1906, the parts of Ireland from which drawn, the number and classes of landholders among the emigrants, their distribution, conditions of work and living, earnings and savings in England and Scotland, etc.

The returns show the number of migrants in 1906 to have been about 25,000, of whom 1,000 were women. Three-fourths are natives of the Province of Connaught, and half the number are from the county of Mayo alone. As regards landholding, definite returns by the constabulary show that of 15,286 migratory laborers in 1906, 11,914 did not hold any land, 497 had holdings not exceeding 5 acres, while 2,875 had holdings of over 5 acres. The quantity of land held, therefore, was in most instances not sufficient to provide a living without other source of income. The chief work of the emigrants was as potato growers and harvesters, while wages ranged "from a lower limit of 15s. a week, with lodging and some food, to piece-work earnings, which at the busy season in several districts reach 30s., and in some cases even £2 a week." It is estimated that the agricultural migratory laborers remitted or brought back to Ireland in 1906 savings amounting approximately to £275,000.

The scarcity of farm help, HEINRICHSEN (*Fühling's Landw. Ztg., 56 (1907), No. 13, pp. 470–475*).—The author calls attention to the depopulation of rural districts in Bavaria, and assigns as causes of this movement the higher wages received by laborers and servant girls in cities and the freer life and easier or more congenial employment to be found there.

Among the remedies suggested to bring about the return of the people to the land may be mentioned the application of industrial methods to agriculture, especially in the use of improved implements and machinery, better food and shelter for laborers, the erection of small houses for the use of laborers' families, the granting of small holdings, and the creation of a class of peasant proprietors.

The comparative costs of the cultivation of land by power machinery and animals, W. CLAASSEN (*Deut. Landw. Presse, 34 (1907), No. 63, pp. 511, 512*).—The author compares the cost of plowing and cultivating different kinds of lands by means of steam and other power machinery with the cost of cultivating land with horses or oxen. The cost of power machinery for the small farmer is regarded as prohibitive, but where the character of the land permits and a steam plow can be procured through cooperative societies it is believed to be of unquestionable advantage. Team plowing and cultivation, however, rather than working with a single animal, are believed to be best for the average farmer.

Agricultural cooperation in Belgium (*Bul. Mens. Off. Renseig. Agr. [Paris], 6 (1907), No. 5, pp. 573-585*).—The data presented in this article were furnished by the different cooperative societies to the minister of agriculture in 1906, and are grouped under 5 general divisions.

The returns at the close of 1905 show 814 agricultural federations, composed of those who are engaged in one particular industry, as hop raising, beet culture, the production of goats, horses, dairy cows, pigs, etc. In addition there were 907 societies with 53,016 members for the cooperative purchase of seeds, fertilizers, feeding stuffs, and machinery, 552 cooperative dairies with 55,118 members controlling the products of 146,674 cows, and 960 live stock insurance societies with 84,983 members insuring 249,273 head of stock. Statistics are also given on the progress of the agricultural banks and credit societies, including their number, loans, deposits, forms of security, number and classes of borrowers, etc.

Agricultural credit in Sicily and its application according to law, C. GRIMALDI (*Bol. Quind. Soc. Agr. Ital., 12 (1907), No. 12-13, pp. 474-494*).—A brief sketch is given of the laws relating to agricultural credit in Sicily, and the different credit societies formed under the laws with the means of giving and securing credit to different classes of peasants are discussed.

Agricultural exchanges, F. NICOLLE (*Jour. Agr. Prat., n. ser., 13 (1907), No. 24, pp. 749-752*).—The author advocates the organization of cooperative agricultural exchanges in France for the sale particularly of cereal products in order to bring larger returns to producers by eliminating in great measure the profits of middlemen. He believes that the cooperative associations now in active operation are the proper means to this end.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 9 (1907), No. 10, pp. 73-80*).—Statistics on the condition, acreage, yields, and prices of agricultural products in the United States and foreign countries are summarized and discussed.

Official report on the condition of crops, also tables of agricultural statistics for 1905 and 1906 (*Ohio Dept. Agr., Div. Crops and Stock Statis. Rpt., 1907, pp. 44*).—The condition of crops on August 1, 1907, and statistical data for 2 years collected by county auditors and reported to the State secretary of agriculture are reported.

Preliminary returns of the agricultural census of Austria from June 3, 1902, F. R. VON JURASCHEK and W. SCHIFF (*Österr. Statis., 83 (1907), Sup., pp. 45*).—Tabulated data on the acreage devoted to different forms of agricultural production, yields of crops, number of live stock, use of machinery, number of persons of both sexes engaged in agriculture, etc., are reported.

Report on the profitableness of agriculture in Switzerland during 1905 (*Ann. Agr. Suisse, 8 (1907), No. 2, pp. 13-112*).—In addition to reviewing the agricultural conditions of Switzerland for 1905, a detailed report is presented of the receipts and expenditures from different-size farms. The receipts from 206 farms averaging 13.35 hectares in size were at the rate of 477.85 francs per hectare, while the average expenses per hectare were for labor

286.05 francs and miscellaneous 141.55, a total of 428.20 francs. The calculated average profit, therefore, amounted to 49.65 francs per hectare. The results of the investigations are tabulated and discussed in detail.

AGRICULTURAL EDUCATION.

Country life education, A. C. True (*Ann. Rpts. Bd. Agr. Del., n. ser., 5–6 (1905–6), pp. 41–50*).—An address, followed by a discussion, made before the agricultural conference held at Dover, Del., December 18 and 19, 1906, in which a brief outline is given of a system of agricultural education beginning with the common school and going up to the high school and into the college, with the experiment station back of these to obtain the new knowledge that is needed. In the opinion of the speaker public education should be supported primarily by the State, but local communities should be taxed sufficiently to maintain an acitve interest in educational matters.

Agricultural education in Delaware, H. Hayward (*Ann. Rpts. Bd. Agr. Del., n. ser., 5–6 (1905–6), pp. 50–61*).—This paper, read at the agricultural conference noted above, discusses briefly the advantages of agricultural education, how agricultural education takes the drudgery out of farm life, competition in agriculture, agricultural conditions to-day, what is to be done in Delaware in the way of education and experimentation as shown by a careful study of what is being done in other States, what Delaware has done for her agricultural interests, the farmers' institute, the equipment of the agricultural department of Delaware College as compared with that of the department of mechanic arts, the needs of the agricultural department of the college and station, and particularly the need of a farm.

Report of the committee on children's gardens for the year 1906, H. S. Adams (*Trans. Mass. Hort. Soc., 1906, II, pp. 176–216, pls. 7*).—This report contains brief accounts of the Children's Garden Conference held December 15, 1906, in Boston; school garden, school grounds, and children's home garden competitions; children's exhibitions; and abstracts of addresses made at the conference, as follows: The Educational Value of School Gardens, by H. G. Martin, Boston; Horticultural Education for School Garden Teachers, F. A. Waugh, Amherst; School Garden Work and the Normal School, W. A. Baldwin, Hyannis; Children's Gardens and the Public, F. M. Marsh, Fairhaven; and The School Farm at De Witt Clinton Park, H. G. Parsons, New York City. Reports are given on the South End industrial school garden, Roxbury; Orphans' Home garden, New Bedford; South Natick garden club; Wellesley village school gardens; Cobbett School garden, Lynn; and school gardens, Fairhaven; on the improvement of the Tracy School grounds, Lynn, and on children's home gardens. A list of prizes and gratuities awarded in 1906 is added.

Hints for school gardens, A. H. Kirby (*Imp. Dept. Agr. West Indies Pamphlet, 48, 1907, pp. 56, dgm. 1*).—This is a revision of a pamphlet published in 1901, and contains general instructions as to size of plats, discipline, distances for planting and period of growth, directions for box and pot cultivation, eight preliminary lessons in the garden, special instructions for growing different vegetables, and directions for budding, grafting, and pruning. Practically every primary school in the West Indies now includes elementary agriculture in its curriculum, and this pamphlet is intended for the use of the teachers in these schools.

Spring in the school garden, Susan B. Sipe (*Atlantic Ed. Jour., 2 (1907), No. 8, pp. 22–24, figs. 5*).—Suggestions are given for planting the school garden, conducting the work, and correlating it with other instruction.

Farm arithmetic and field investigations, G. F. GARRETT (*Jour. Ed.* [*Boston*], *65* (*1907*), *Nos. 14, pp. 377, 381, 382; 15, pp. 410, 411; 17, pp. 458, 459*).—In part 1 of this article 11 farm problems and investigations are given. These relate to land measurements, cost of production, net profits, relative feed values, losses in storage, weights and measures, dairy problems, and the conditions of growing wheat. Part 2 shows how some Iowa boys make money, namely, by entering a corn contest at the State fair, by milk testing during summer vacations, and by caring for a cow and selling clean. rich milk. Part 3 gives an explanation of how the earth breathes.

The soil and its relation to plants, B. M. DAVIS (*Miami Bul., 6. ser., 1907, No. 3, pp. 35, figs. 6*).—This is Teachers' Bulletin No. 1 of the Department of Natural History and Elementary Agriculture, Ohio State Normal College, Miami University, Oxford, Ohio. The exercises outlined represent work that has actually been done by pupils of the sixth to eighth grades. The bulletin is intended as an aid to teachers in introducing elementary agriculture into their schools, and includes 21 experimental studies relating to the root systems of plants, water in soils, soil formation, kinds or types of soils, some of the physical characteristics of soils, and the relation of soils under different conditions to plant growth. Lists of reference books and pamphlets and apparatus required for the work outlined, as well as means for keeping plants alive during cold weather, are appended.

Western Illinois State Normal School soil experiment field, J. T. JOHNSON ([*West. Ill. State Normal School*] *Circ. 1, pp. 4*).—A statement of the purpose, location, and plans of conducting the field.

The Grout farm encampment, A. J. BILL (*Agr. Col. Ext. Univ. Ill.* [*Circ.*], *1906, Dec., pp. 42, figs. 10*).—This is an account of an agricultural education encampment by 54 boys on the farm of A. P. Grout, Winchester, Ill. Besides various forms of entertainment, regular lessons in agriculture were provided.

[Dairy lessons for public schools], W. J. FRASER (*Agr. Col. Ext. Univ. Ill., 1907, Dairy Lessons 1, pp. 4, figs. 4; 2, pp. 8, figs. 5; 3, pp. 4, figs. 3; 4, pp. 4, figs. 2*).—These 4 circulars treat of the following topics: Story of Gold and Gilt, when the cows come home, cow paths that lead far apart, and the bondage of the dairyman.

Nebraska corn book, E. C. BISHOP (*Lincoln, Nebr.: Dept. Pub. Instr., 1906, pp. 80, figs. 48*).—This is a manual prepared for the boys and girls of Nebraska taking part in the corn-growing and cooking contest of 1907. It gives directions for contestants and exhibitors, and information concerning the history of corn, its use as food, its structure and composition, the selection and testing of seed corn, the growing of corn, and rules for judging corn exhibits. Less detailed information is given for wheat, oats, rye, barley, rice, potatoes, and sugar beets.

For exhibitors in the domestic science work there are directions for the preparation of exhibits, recipes for cooking and canning, and some instructions in needlework.

Nebraska Boys' and Girls' Associations—Organization, E. C. BISHOP (*Univ.* [*Nebr.*] *Bul., 12. ser., 1907, No. 16, pp. 3, 4*).

Corn cultivation, V. KEYSER (*Univ.* [*Nebr.*] *Bul., 12. ser., 1907, No. 16, pp. 5–12, figs. 2*).—For instruction of boys who entered the Nebraska corn contests.

Corn, cotton, and chicken contests for Georgia schools and school children, 1907 (*Bul. Univ. Ga., 7* (*1907*), *No. 4, pp. 48, figs. 21*).—Announcements concerning the contests for 1907 are followed by suggestions for the study of corn, cotton, and poultry, including score cards for each of these.

A little lesson in judging cattle, C. S. PLUMB (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], *2* (*1907*), *No. 9, pp. 4–10, figs. 10*).

Local weather signs, J. W. SMITH (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], *2* (*1907*), *No. 9, pp. 11-13*).—The following subjects are considered: Clouds, barometer changes, humidity, sun spots and the weather, and the moon and the weather.

Mosquitoes, H. OSBORN (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], *2* (*1907*), *No. 10, pp. 4-12, figs. 8*).—An account of where mosquitoes lay eggs, what changes take place before they can fly, how the number may be diminished, and how malaria may be spread by mosquitoes.

Drainage, A. G. McCALL (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], *3* (*1907*), *No. 1, pp. 4-10, figs. 9*).—An elementary lesson in drainage, with illustrations to suggest experiments in drainage.

MISCELLANEOUS.

Twentieth Annual Report of Maryland Station, 1907 (*Maryland Sta. Rpt. 1907, pp. XX+318*).—This contains the organization list, a report by the director on the work and expenditures of the station, a financial statement for the fiscal year ended June 30, 1907, and reprints of Bulletins 110-118.

Thirteenth Annual Report of Montana Station, 1906 (*Montana Sta. Rpt. 1906, pp. 99-184*).—This contains the organization list and financial statement for the fiscal year ended June 30, 1906, a report of the director on the general work of the station during the year, lists of station publications, donations, loans, and exchanges, and departmental reports, the experimental work of which is noted elsewhere in this issue.

Seventeenth Annual Report of New Mexico Station, 1906 (*New Mexico Sta. Rpt. 1906, pp. 66*).—This includes the organization list, a report of the director on the work and publications of the station, a list of station publications available for distribution, departmental reports on the various lines of station work conducted during the year, and a financial statement for the fiscal year ended June 30, 1906. Reports of the work in horticulture, irrigation, and animal husbandry are noted elsewhere in this issue.

Sixteenth Annual Report of Oklahoma Station, 1907 (*Oklahoma Sta. Rpt. 1907, pp. 64*).—This contains a report of the director, a list of station publications available for distribution, a summary of the press bulletins issued during the year, meteorological observations noted elsewhere in this issue, and a financial statement for the fiscal year ended June 30, 1907. The press bulletins are in part a repetition of matter published in the regular bulletins of the station. Those not abstracted elsewhere in this issue treat of Oklahoma wheat experiments, wheat pasture experiments, dairy work at the college and station, and summer forage crops.

Experiment Station Work, XLII (*U. S. Dept. Agr., Farmers' Bul. 305, pp. 32*).—This number contains articles on the following subjects: Extension of rice culture, growing seed potatoes under mulch, manure as a summer mulch in forcing houses, renewal of old orchards, injury by Bordeaux mixture, gluten flours and similar foods, laxative properties of wheat bran, emmer as a feeding stuff, roots for farm animals, cabbage as stock feed, pasturing hogs, cull beans as a feed for hogs, and healthy poultry.

Accessions to the Department Library, April-June, 1907 (*U. S. Dept. Agr., Library Bul. 64, pp. 75*).

Annals of the royal agricultural high school of Portici (*Ann. R. Scuola Sup. Agr. Portici, 2. ser., 6* (*1906*), *pp. 402, pls. 9, figs. 49, map 1*).—The first series of these annals cover the period 1875 to 1898. The second series brings the reports of investigations up to 1906 and includes mainly papers on the effect of electricity on plants, chemical studies of volcanic rocks and soils, particularly those of Vesuvian origin, effect of fluorids on germination of seeds, histological and chemical studies of plants, malaria and sanitation, and studies on *Anajapyx vesiculosus*, *Litomastix truncatellus*, a new species of Coccidæ, classification of Leucaspis, and polymelia of the ilium and polydactyly in cattle.

Sixth annual general report of the department of agriculture and technical instruction for Ireland (*Dept. Agr. and Tech. Instr. Ireland, Ann. Gen. Rpt., 6 (1905-6), pp. VI+551*).—This report gives the administration and work of the department for the year 1905-6.

NOTES.

California College.—Among the short courses announced for the coming winter at the university farm at Davis is one in wine making and wine testing from January 2 to 8, which is intended for wine makers of some experience.

Connecticut State Station.—Harry R. Stevens has been appointed chemist.

Illinois University and Station.—Eugene Funk has been elected a member of the board of trustees. An appropriation of $7,500 annually was granted by the last legislature for investigations in floriculture. An advisory committee of five members of the State florists' association and the director is to decide upon the lines of work to be carried on. A. C. Beal has been appointed assistant in floriculture in the station.

Indiana Station.—A horticultural and soil improvement special train was run through the southern part of the State from November 19–22, as the result of cooperation by the railway companies in equipping and operating the train, and the station and State horticultural society, which furnished the speakers. The horticultural lectures were in charge of C. G. Woodbury, and the soil improvement work, which dealt largely with the use of fertilizers, was under the supervision of Director Goss. A dairy special train, operated along similar lines and in charge of members of the dairy department of the station and representatives of the State Dairy Association, was operated from December 9–13.

Kansas College and Station.—The new State fertilizer law, under which the fertilizer control work is transferred from the State board of agriculture to the station, went into effect September 30. A text-book on elementary agriculture, written by different members of the college faculty, will be issued in a series of monthly pamphlets under the direction of the superintendent of college extension. A pamphlet on Soils has already been issued, and others will follow on How Plants Feed, Tree Culture, Birds and Insects, Hygienic Cookery, Live Stock on the Farm, etc. The *Industrialist* notes the recent death of Rev. Elbridge Gale, professor of botany and horticulture from 1870–1878.

Louisiana Stations.—J. G. Lee has resumed his duties as assistant director of the Calhoun Station, after a year's leave of absence on account of ill health, and J. B. Garrett, who has been acting director, has taken up entomological work in the sugar-cane district.

Some cooperative experiments have been arranged by this station with the Forest Service of this Department in the preservation of fence posts, and the use of loblolly, or old field pine, for this purpose. Good fence-post timber is becoming rather scarce, and it is expected that this species of pine, which is quite abundant, can be profitably used for fence posts, shingles, and other farm purposes. E. J. Watson, for many years horticulturist of the station, and J. R. Hall, chemist at the Audubon Park Station, have resigned to engage in commercial work. J. G. Grossenbacker, of the New York State Station, has been appointed plant pathologist of the Baton Rouge Station.

The Audubon Park Station, with the assistance of the New Orleans Park Commission, has succeeded in producing more than one hundred seedling sugar canes during the past year, some of which made remarkable growth. The cuttings are now being planted for the next year's crop.

Massachusetts Station.—The station is forming plans for substation experiments in fruit culture, especially apples, in a number of different localities. A 3-acre cranberry bog has been leased in Wareham for a term of 5 years, and will be used primarily for experiments in methods of control of cranberry insects. Walter E. Dickinson has resigned as assistant chemist.

Missouri Station.—L. D. Haigh, a graduate of the University of Michigan, has been appointed assistant in agricultural chemistry.

Nebraska University.—The forest club of the university is holding a series of lectures dealing with the forest trees of the world, forest insects, fungus diseases of trees, forest conditions, the handling and utilizing of the National forest reserves, and related topics.

North Dakota College.—A correspondence course in agriculture has been established for residents of the State. It is stated that, while the course is open to all classes, it "should appeal especially to teachers who will soon be teaching agriculture in the schoolroom."

Pennsylvania College and Station.—The new group of agricultural buildings was dedicated with appropriate ceremonies on November 22, which was designated as Pennsylvania day. The principal dedicatory address was made by Director Jordan, of the New York State Station. Governor Stuart of Pennsylvania, Acting President Beaver of the college, Director Hunt of the station, and Dr. N. C. Schaeffer, superintendent of public instruction and chairman of the allied agricultural organizations, were also among the speakers.

The buildings just dedicated are among the most completely equipped for agricultural instruction in the country. The main building is a two and one-half story structure, 158 by 73 ft. Adjoining and connecting directly with it in the respiration calorimeter building, a one-story structure 56 by 35 ft. A substantial two-story dairy building completes the group. The base in all of the buildings is of Hummelstown brownstone, with brick superstructure and terra cotta trimmings, and the main building and the dairy building are of fireproof construction. The cost of the entire group was over $300,000.

The main building contains, in the basement, the offices, library, and laboratories of the Institute of Animal Nutrition, a judging room for live stock, facilities for demonstrating methods of handling meat, a laboratory for farm machinery, and rooms for the mailing department. On the first floor are located the offices of the dean and director and of the department of agricultural extension, the class rooms and laboratories of the department of agronomy, the libraries of the school and station, and an assembly room. The second story will be occupied by the departments of animal husbandry and agricultural chemistry, the correspondence courses, and, temporarily, by the department of horticulture. The dairy building contains a creamery, with all modern equipment for making butter, handling sanitary milk, and preparing ice cream, a cheese-making room with vats, presses, and other necessary equipment, rooms for instruction in farm dairying, milk-testing and bacteriological laboratories, and several offices and class rooms.

South Carolina College and Station.—C. E. Chambliss, formerly entomologist, has been appointed State entomologist with headquarters at Columbia, where he will continue his investigation of the insects distributing the rice blast disease. Dr. E. Barnett has been appointed assistant State veterinarian.

Texas College and Station.—C. E. Sanborn, of the Bureau of Entomology of this Department, has succeeded A. F. Conradi as entomologist.

Virginia College.—Short winter courses for farmers in agriculture, animal husbandry, horticulture, and dairying have been offered for the first time, beginning December 2 and continuing 3 weeks. Lectures were given in agricultural chemistry and fertilizers, soils and maintenance of fertility, stock breeding and feeding, dairying, fruit growing and marketing, farm crops, farm machinery, land measurement and leveling, birds, insect pests and plant diseases, and demonstrations in stock judging, dairying, farm machinery, silo and ensilage machinery, fruit spraying, etc.

West Virginia College.—A good-roads school will be opened February 23, 1908, and continued for 4 weeks. The State department of good roads, the State geological survey, and the inspector of highways will cooperate with the university in conducting this school.

New Experiment Stations in Mexico.—Pursuant to an offer of the Mexican federal government to give land for the establishment of an agricultural experiment station in the State of Puebla, an estate of 2,470 acres at Xopala, in the district of Zacatlan, has been selected. The location of this station is about 60 or 70 miles from the coast in a northeasterly direction from the City of Mexico, where the climate is moist and hot, and the principal agricultural productions are vanilla, coffee, cacao, sugar cane, rubber, medicinal and dye plants, sarsaparilla, citrus fruits, etc.

Petitions are being circulated in San Juan Bautista with the idea of appealing to the department of the interior for cooperation in the establishment of an agricultural experiment station in that State.

Guam Experiment Station.—The agricultural experiment station organized in Guam in 1905 has begun the dissemination of information through bulletins for free distribution to residents of the island. Bulletin No. 1 treats of vegetable growing, and No. 2 of means of combating the cocoanut scale.

Apiculture Stations in Wurttemberg.—Under the leadership of Herter a system of 15 apiculture stations has been established in Wurttemberg for the purpose of making accurate daily observations upon the amount of honey gathered by each swarm, the work of the bees, and the weather conditions. These data are tabulated and forwarded to the director at Hohenheim, who collates and publishes them for the benefit of the beekeepers in Wurttemberg.

New Journals.—The members of the Association for the Advancement of Agriculture and Animal Husbandry for Venezuela have undertaken the publication of a weekly, entitled *Revista de Agricultura y Cria.*

The *Journal of the Board of Agriculture of British Guiana* has been established as a quarterly, with the object of "supplying in a popular form information of an agricultural character suited to the requirements of this colony."

Forestry Notes.—At the Pennsylvania State Forest Academy, which is conducted under the direction of State Forester G. H. Wirt, work has begun on a new $15,000 dormitory. The school offers a three-year course consisting of practical work in the summer months on the Mount Alto Reservation and class work during the winter months. Ten students have graduated from the institution and 29 are now enrolled.

Harvard University has recently received a gift of about 2,000 acres of forest land in central Massachusetts, besides $5,000 for the repair and equipment of buildings. The tract, which is considered one of the best forests in the State, will be utilized for practical work by the forestry school.

The British Government has acquired a 12,000-acre estate known as Inverliver, in Argyllshire, Scotland, for the purpose of converting it into a state forest station. The estate is situated on the shores of Loch Awe, in one of the most sparsely populated districts of the Highlands, and is surrounded by mountains and moorland.

A committee has been appointed to inquire into and report upon the question of the improvement of forestry in Ireland. Among the topics to receive special attention will be the present provisions for state aid to forestry, the means whereby under the present statutes existing woods may be preserved and land suitable for forestry acquired, and the financial and other provisions necessary for a comprehensive scheme of afforestation.

A recent consular report states that through the influence of the Touring Club of France a manual of elementary forestry has been introduced into the primary schools of that country. This club has also published a Manual of Forests illustrating the advantages of preserving the forests of the country and containing a constitution and by-laws for tree-planting societies.

Agricultural Education.—A writer in the London *Times* says: To one very important condition of success both advocates and opponents of *la petite culture* in England pay, we suspect, too little regard—namely, the improvement of agricultural education, for the heads as well as for the rank and file of the industry.

In too many of our country districts it is hardly yet realized that education is necessary at all. Landowner and tenant farmer are alike disposed to lay blame for the rural exodus on such education as is given to the laboring classes—an education which it may be admitted has not always been best adapted to fit them for a country life and pursuits. But they forget that education is, after all, but an incident of the great social and economic changes that have come over English life in the past half century, and that if all our elementary schools could be restricted to-morrow to teaching "the three R's" and all boys sent out to farm work at 10 or 11 years of age there would still remain the daily newspaper, the bicycle, and the excursion train to give the laborer that wide outlook and "progressive desire" which is what really draws him away from the land.

So far from there being, as Squire Oldacre and Farmer Hodge are apt to think, too much education already, what is needed is much more of it, but of a different kind; education in the elementary school that will bear directly on country life and inspire some taste for it; education continued afterwards in evening schools or technical instruction classes to widen the knowledge and sharpen the wits of those who are to cultivate the soil and to instill into them at least the beginnings of scientific method. The day of rule-of-thumb is over, in agricultural as in other industries; the day of science—that is, of trained and organized knowledge—has begun, and the nation or class that despises it must fall behind.

It is not undue treatment in freight charges nor unpatriotic preference for foreign goods that enables the small Danish butter farmer, for instance, to undersell the Englishman on his own markets, but superior education and scientific method applied to the organization of his industry; and we may be sure of this, that it will be useless to keep a man on the land, or to bring him back to it, by the inducement of ownership or any other attraction unless we can educate him to do the best for himself and for the land, in an age which calls for cultivated intelligence and scientific method.—The London *Times*, quoted in *Science*.

First Agricultural High School in Michigan.—The first county school of agriculture and domestic science to be organized under the Michigan law of 1907 was opened at Menominee on November 18. The two-year course recommended by the State superintendent of public instruction will be followed. J. F. Wojta, formerly of the Minnesota School of Agriculture, has been chosen superintendent.

A New County School of Agriculture in Wisconsin.—Bulletin No. 1 of the Winnebago School of Agriculture and Domestic Economy has been received. This school is located at Winneconne, Wis., and was opened to students November 4. K. L. Hatch, formerly superintendent of schools at Waterloo, Wis., has been elected principal and teacher of agriculture. The courses in agriculture and domestic economy will be very similar to those offered by the schools in Dunn and Marathon counties.

Agriculture in Alfred University.—Courses in general agriculture, horticulture, advanced agronomy, and economic entomology were offered in Alfred University, Alfred, N. Y., during 1906–7, and it is announced that additional courses will be given as needed in the future.

An Agricultural School in Bolivia.—A recent bulletin of the department of colonization and agriculture of Bolivia announces that the legislature has appropriated $8,200 for the establishment of an agricultural school at Cochabamba. The exact location for this school is now under consideration. It is the intention to develop this institution into a national institute of agriculture, with other institutions to be established in the country, as follows: A practical school of agriculture and animal husbandry at Tarija, a viticultural and enological station or school at Cinti, a special school of tropical agriculture at Santa Cruz, an office or station of zootechny and veterinary medicine at Trinidad, and a special high-altitude agricultural school for La Plaz, Oruro, and Potosi.

Agricultural Education in Scotland.—At the annual conference of the Scottish Chamber of Commerce in Glasgow, October 23, resolutions were adopted favoring the inclusion of agriculture in the curriculum of the day schools, and instructing the directors to take the necessary steps for bringing this about. The Board of Agriculture and Fisheries was requested to consider the appointment of a departmental commission to inquire into the present condition of agricultural education and research in Scotland, the commission to correspond in scope to that now in progress in England.

Agricultural Education in Austria.—According to a note in a recent number of *Wiener Landwirtschaftliche Zeitung*, there were in 1906–7 195 institutions in Austria giving instruction in agriculture and forestry.

These include 6 institutions established within the year, namely, the agricultural division of the Royal Imperial Technical High School at Prague, the Royal Imperial Agricultural Educational and Experimental Institute at Spalato, the farm school at Mikozin, agricultural winter schools at Judenburg and Friesach, and the domestic science school at Chrudim.

The schools making up the total include the following: Three high schools, 3 higher agricultural institutes or academies, 9 agricultural secondary schools, 5 higher forestry institutes, 2 higher institutes for viticulture, pomology, and horticulture, 1 higher institute for the brewing industry, 43 lower agricultural schools, 75 agricultural winter schools, 10 lower forestry schools, 17 dairy and domestic science schools, 23 lower special schools for gardening, pomology, viticulture, and hop, alpine, and bee culture, 2 brewing schools, and 2 distillery schools.

The Growth of People's High Schools and Agronomic Schools in Denmark.—According to figures recently published by the Danish bureau of statistics, the number of people's high schools in that country has increased from 3 in 1844 to 71 in 1906, while the attendance in these institutions has grown from 36 to 6,282. Of agronomic schools, there were 5 in 1844, while now there are 14 and the attendance has increased from 42 to 1,126.

Elementary Agriculture and Forestry in Belgium.—The communal council of Schaerbeck has decided to give instruction in the elements of horticulture and forestry in one of the parks of Brussels to pupils from the primary schools.

During the winter of 1907–8 short courses in elementary agriculture will be held in 346 communes of the Kingdom, each course to be accessible to not more than 20 pupils.

Proposed Scheme of Agricultural Education in the Argentine Republic.—An advisory commission has reported to the minister of agriculture of the Argentine Republic a scheme for a system of agricultural education in that country, including different grades of theoretical instruction in agriculture, schools for instruction in special branches of agriculture, practical instruction in agriculture, etc., and has drawn up a proposed law embodying its recommendations.

Agricultural Education in Victoria, Australia.—The farmers' classes organized by the department of agriculture in 1902, when they were held in 3 centers, have increased in number until in 1906 they were held at 18 centers, with an attendance of 1,320 persons. During the present year arrangements have been made for conducting the classes in 26 centers.

Attached to the viticultural station, at Rutherglen, is an area of 800 acres which it has been decided to work as a general farm, and at the same time to utilize the buildings originally intended for a college as an educational center for the orphans from the neglected children's department. Twenty-two boys are now being trained in farm and vineyard work, and preparations are complete for receiving 15 more boys. One hundred acres are cultivated, and there are 300 sheep and 70 cattle, chiefly dairy cows, on the farm.

The agricultural high schools which have been recently opened at Warrnambool and Sale are said to be receiving good support, and active steps are being taken to establish four others. The conditions for the establishment of these schools provide that half the cost of the buildings shall be obtained locally, together with 20 acres of land, and that an attendance of at least 50 pupils shall be guaranteed at a fee of about $40 a year each.

Short Courses in Agriculture in the Transvaal.—Vacation courses, comparable to short winter courses in American colleges of agriculture, were held during the 3 weeks following June 24 at the Rhodes University College. The subjects included veterinary science and diseases of stock, breeding of Merinos and Angoras, agricultural chemistry, agricultural geology, farm irrigation and dam construction, law of water and water rights, plant diseases, ostrich raising, insects and insect control, mechanics and meteorology, and farm surveying and leveling.

Extension of Agricultural Institutions in Spain.—An act of October 12 provides for the establishment of an experiment field with irrigation equipment on the Santa Teresa Estate, near Seville, for educational and experimental purposes, a laboratory and educational institution in connection with the agricultural school at Madrid, and an experiment field at Motril, in the Province of Granada. The organization and equipment of these institutions has been placed in charge of the state engineer for agriculture of East Andalusia, under the supervision of the general director of agriculture of the ministry of public works.

The United States Consul-General at Barcelona reports the promulgation of a recent government order creating traveling schools of agriculture for the remote districts of Spain. The order provides for a course of experimental and practical instruction to be given every year by itinerant lecturers selected from the agricultural engineers of the district schools of agriculture located at Zaragoza, Jaen, Palencia, Badajoz, and Barcelona, and the two stations at Haro and Villafranca del Panadés.

Itinerant Agricultural Instructors in Trinidad.—Instruction in agriculture by means of itinerant lecturers has been carried on in Trinidad since 1902. These instructors visit any plantation upon application of the owner and also give lectures in schools and other public places. During the past year 260 visits were made in 52 different places and 564 lectures were given. One hundred and forty visits were made to schools and 32 lectures were given at the training school.

Farm and Home Management School for Women.—A recent number of *Illustrierte Landwirtschaftliche Zeitung* gives an interesting account of a school for women at Maidburg, Germany, which affords training in home economics and agricultural subjects intended to prepare women to take charge of farm homes, including the kitchen, garden, poultry, etc. Adjacent to this school is a training school which affords facilities for young women who wish to prepare to teach home economics. A similar school is to be opened in the spring of 1908 at Scherpinger, in West Prussia. One of the possible developments of schools of this class, it is suggested, will be to make them social and educational centers for the rural communities, with lectures, entertainments, and libraries maintained in connection with the schools for the benefit of all the people in the vicinity.

School Gardens.—A series of articles on this subject is contributed by H. J. Wright to *Agricultural Economist.* Detailed instructions for the cultivation of different crops are given.

It is announced in *The Country Gentleman* that the Chautauqua Institution offers to provide 6 weeks' preliminary training in school gardening next summer to any rural school-teacher in Chautauqua County who will undertake this work and carry it out as a feature of elementary instruction in agriculture. The Chautauqua Pomona Grange will aid in perfecting plans for this course and will arrange for 6 scholarships to further promote the work.

In Ceylon there are now 117 government schools in which gardens are being carried on. The seeds and implements are supplied by the government, and the gardens are visited as often as possible by the superintendent of school gardens and his assistant.

State Department of Apiculture in Germany.—A State department of apiculture, under the direction of Dr. A. Fleischmann, was established on November 1 in connection with the Zoological Institute of the University of Erlangen. This institution includes a scientific division under the direction of Dr. Enoch Zander, and a practical division under the direction of Karl Hofmann. The *Deutsche Landwirtschaftliche Presse* in its account of this new institution calls attention to the fact that it is the first of its kind in Europe.

French Silk Schools.—According to the *Journal of the Society of Arts*, two schools in Lyon teach silk culture. One of these (Ecole Supérieur de Commerce) receives pupils from foreign countries and teaches them the entire silk business from the raising of the worm to making the designs, weaving the silk, and putting it on the market. The course of study covers two years. The second school (Ecole Municipal de Tissage et de Broderie) is conducted by the city and is intended only for the children of the inhabitants, although foreigners are received on equal terms with the natives.

Measures before Congress.—Bills introduced into Congress at the opening of the session include the following: For the maintenance of agricultural colleges in Congressional districts, to establish branch experiment stations, to establish agricultural high schools and branch experiment stations connected therewith, to establish a Bureau of Public Roads in this Department, directing the Office of Public Roads to cooperate under certain conditions in the improvement of rural roads, to acquire national forest reserves in the Appalachian Mountains, for national aid in various drainage projects, to establish a national wood-testing laboratory, authorizing further experiments and demonstrations by this Department with the cotton boll weevil and other pests, and providing additional funds for the eradication of the Texas fever tick and the gipsy moth. Most of these measures were introduced into the last Congress, but failed of passage.

Northwestern Live Stock Show.—The first annual show of this association was held at St. Paul, November 19–22. The North Dakota College won a large number of prizes, especially in the swine classes, and the Minnesota College of Agriculture had a notable exhibit, though not entered for competition. W. J.

Kennedy, of the Iowa College and Station, was one of the judges, and among the speakers and demonstrators from the colleges and stations were J. H. Shepperd, of North Dakota; Director Randall, D. A. Gaumnitz, and M. H. Reynolds, of Minnesota, and A. T. Peters, of Nebraska. A student stock-judging contest, in which 4 colleges participated, resulted in the award of first and third places to Minnesota, second, fifth, and eighth to South Dakota, fourth and fifth to Washington, and sixth to North Dakota.

Miscellaneous.—W. R. Buttenshaw, botanist in the Indian Agricultural Service, died suddenly September 9, at the age of 30 years. He was from 1899–1903 lecturer in agricultural science in Jamaica, and scientific assistant in charge of publications at Barbados until May, 1907.

A studentship in medical entomology was recently established at Cambridge University on the basis of a grant from the tropical diseases research fund, administered by the British colonial office. A. H. Lees, King's College, has been appointed to the position.

B. N. Wall has been appointed head of the agricultural department in Southeastern Agricultural College, W. G. Godwin head of the chemical department, and C. F. Gimingham head of the newly established department of soil bacteriology.

The *Boletim da Agricultura, Viacao, Industria e Obras Publicas* of Bahia, Brazil, announces the establishment this year of an agricultural institute under the direction of Dr. L. Zehntner.

A department of economic biology has been established at Bristol University College for the purpose of giving gratuitous information to farmers, fruit growers, and those engaged in fisheries in the western counties of England.

The Minister of Industries and Public Works of Chile has ordered the establishment of a veterinary station under the direction of Francisco Calvanese in connection with the Practical School of Agriculture at Concepcion, similar to the station now connected with the Normal School of Agriculture at Santiago.

According to a note in *Science*, Daniel Berthelot has been appointed director of the laboratory for plant physics and A. Muntz director of the laboratory for plant chemistry at the Meudon Experiment Station.

Prof. M. Hollrung has severed his connection with the Experiment Station for Plant Protection at Halle, and the station has been united with the Agricultural Chemical Experiment Station at that place, and transferred to the rooms of the latter institution.

A recent number of *Illustrierte Landwirtschaftliche Zeitung* states that Doctor Lubers, of the agricultural school at Dahme, on October 1, has become director of the newly opened agricultural school at Bojanowo, in the Province of Posen.

The Lieutenant-Governor at Libreville, in the French Kongo, has issued an order designating Director Bories, of the Trial Garden at Libreville, as instructor in practical agriculture in the normal school of the Colony of Gabon.

O

EXPERIMENT STATION RECORD.

VOL. XIX. JANUARY, 1908. No. 5.

The position of agricultural chemistry as a teaching subject in German universities and schools of agriculture has become a matter of apprehension on the part of its followers, and has lately been the subject of discussion in the public press. The chief parties to the discussion have been the Association of German Experiment Stations and the Director of the Ministry of Agriculture, Domains, and Forests, Dr. H. Thiel. As the birthplace of agricultural chemistry and until recently the place of its highest development, this discussion and the facts leading up to it are matters of more than local interest, as well as the bearing of the subject on the organization of instruction and experimentation in agriculture.

There has long been a feeling in Germany that agricultural chemistry was not receiving the recognition due to it, and was not maintaining the position it formerly occupied. Of late, it appears, it has not held out such possibilities for a career as to induce young men to enter it. It is thus considered to be on the wane, as a result of the attitude toward it, and this condition is felt to be detrimental alike to agricultural instruction and to the future of agricultural research.

The importance of this matter led to its being made a special topic for discussion at the meeting of the association last winter. On that occasion Prof. Th. Pfeiffer, of Breslau, presented a paper in which he showed the decline of agricultural chemistry in German universities, and maintained that at present it does not occupy a position commensurate with its importance or equal to that of other branches of agricultural science. Of nine universities concerned only two, Königsberg and Breslau, have full (*ordinarius*) [a] professorships in agricultural chemistry, and four others have only limited professorships, which do not entitle their occupants to a voice in the deliberations of the faculty, and in only a few instances permit them to hold final examinations. Under the German university system this latter provision has considerable influence on the courses elected by students.

---

[a] In German universities professors are of two grades, *ordinarius* (full or unlimited) and *extraordinarius* (limited or subordinate).

The universities of Leipsic, Kiel, and Giessen offer no opportunities for the study of agricultural chemistry under the direction of specialists. In two universities, Göttingen and Halle, full professorships when vacated have been reduced to limited, and in Leipsic, where such men as Knop and Stohmann labored with notable success, agricultural chemistry has been completely dropped. In Kiel, Emmerling was permitted to lecture on agricultural chemistry as a *privat docent* to the end of his life, and since his death no representative of this specialty has been appointed. It was mentioned, furthermore, that at that university not a single full professorship in any branch of agriculture is provided.

The conditions at the agricultural high schools and academies were said to be somewhat better, although not all that could be wished for, the position and activity of the agricultural chemist often being limited. Professor Pfeiffer stated that at present there is not a single *privat docent* in agricultural chemistry in all Germany, and hence there are no young men in training for that specialty. This condition was ascribed to the present position of agricultural chemistry in Germany, and the small future which it holds out to a man entering it.

From its history this specialty was shown to be a most important pillar of agricultural science, fully entitled to rank among the foremost subjects in agricultural instruction. Unless it can be maintained in its former position, it was predicted that the development of agricultural investigation and agricultural instruction in Germany must surely be retarded. In view of the importance of the matter and the inconsistency of the present attitude, it was decided to petition the German Agricultural Council for assistance in bringing about increased attention to the teaching of this subject, and in obtaining fuller recognition for it in German universities.

Closely following the above discussion, Dr. H. Thiel, of the Ministry of Agriculture at Berlin, presented a paper before the International Agricultural Congress at Vienna on the subject of higher instruction in agriculture. In the course of this paper, Doctor Thiel laid down the general proposition that the natural sciences in their applications to agriculture should be taught in the respective departments of these sciences, and not in such departments as agricultural chemistry. He contended that the way should be opened for the agricultural student to learn the principles of natural science on which agriculture rests directly from the general sciences themselves—that is, in those departments of science. This plan, he explained, is ideal at present, and would presuppose the provision in these departments of facilities suited to the special needs of the agricultural student in the form of lectures, laboratories, seminars, and instructors. When these conditions are fulfilled, he maintained that agricultural chemistry, "a bastard made up of the various sciences," can be eliminated from the course of instruction; and he declared that this "stop gap" is out of place except where the needs of the agricultural student are not fully met by the respective branches of natural science.

This characterization of agricultural chemistry and its function was quite naturally resented by the friends of that specialty, not only as being grossly unfair to that subject which has in so large a measure furnished the basis for agricultural instruction, but as a reversion to an obsolete and impracticable system. The matter was taken up at the meeting of the Association of German Stations in September, 1907, and Thiel was replied to in the public press.

It was contended that if Thiel's characterization were true, Liebig, with a large part of his life work, and a long list of other chemists like Henneberg, Knop, Wolff, Boussingault, Gilbert, and others, are to be regarded as "stop gaps," servants of a "bastard science," which has no place in the ideal curriculum. An army of agricultural chemists who are carrying on a work of recognized importance in every country of the civilized world would be dissolved, and those in whose hands the research in plant and animal nutrition has rested since the time of Liebig would have no place in the institutions of learning.

It was shown that the same contention would apply equally well to all applied science, and that logically all such branches must be stricken from the programme as individual departments of study and be restored to the respective departments of pure science on which they rest. What the agricultural chemists formerly taught would fall to the various branches of natural science—chemistry, botany, zoology, geology, etc. But in these departments the student of agriculture would not find what he needs, for, it was pointed out, at no university have the professors in general science concerned themselves with the special needs of the agricultural student, and these professors already have so broad a field to cover that they must needs restrict their lectures to principles and general facts.

Furthermore, the association laid down the broad principle that it is one thing to know the essential facts of a single branch of natural science, and quite another thing to be able to marshal the facts of various sciences and to formulate from them principles which apply to the phenomena of agriculture. Although agricultural chemistry, like all applied sciences, draws its stock in trade from the primary sciences like chemistry, botany, geology, etc., the manner in which it handles these facts makes its methods essentially distinct and gives it an individuality. It is a characteristic and a strength of every applied science, in contradistinction to the primary sciences, that it attempts to work out and master the complex phenomena in the whole range of its field without regard to the limitations of a single science, whereas the primary sciences view the field from a special angle. This point of view is not changed when instruction in chemistry, physiology, botany, etc., is presented to agricultural students with an agricultural color.

The association called attention to the rapid rate at which specialization is taking place within pure as well as applied science, a condition which will continue to increase with the development of science. Agricultural chemistry is, therefore, entirely in accord with the progress of the times, and its retention as one of the special divisions of chemistry is entirely logical.

Doctor Thiel in his reply to the association maintained his contention that the field covered by agricultural chemistry should be assigned to special instructors in the basal sciences, and that when these conditions were met and the agricultural student received thorough and systematic instruction in all the branches of natural science with special reference to agriculture—when he had learned the laboratory methods of chemical, microscopic, physiological, and other lines of work, then the agricultural chemist would have nothing new or important to offer him; and, furthermore, he queried what possible line of questions the agricultural chemist could put in examination which would not be covered equally well by the teachers of agriculture and the various natural sciences.

Enlarging upon his plan he explained the methods of making field and feeding experiments, of studying the soil, and the like, the student would receive in connection with his study of the special sciences, and he refused to recognize in agricultural chemistry any method or point of view which differs in any way from that of the respective sciences "in whose field its investigations lie."

From the standpoint of teaching Doctor Thiel holds that the recognition of such specialties as agricultural chemistry brings with it the danger that the agricultural student, especially when he continues his studies for only a short time, will be tempted to restrict the lectures he hears to those in specialties like agricultural chemistry which give him something of the different sciences, rather than to take the more fundamental science courses. This apprehension is undoubtedly well founded, and such a preference seems so natural for a student with limited time that the question arises, Why not? It is perhaps one of the strongest arguments for agricultural chemistry that it gives the student an insight into the applications to agriculture of principles of science which would otherwise be closed to him.

This further exposition of Doctor Thiel's views met with equal dissension from the agricultural chemists, whose last reply he has declined to discuss. The disagreement on the essential features of organization for agricultural instruction seems to be complete. Some good may, however, result from the airing which has been given the subject.

The proposal to divide up instruction in the principles of agriculture among the various primary sciences is a reversion to a plan which was long tried abroad as well as in this country, and proved entirely inadequate. The plan is not materially strengthened by the supposition that these various sciences are to be taught in their special relations to agriculture, for the limitations of the various sciences considered individually would still stand in the way. The trouble lies with the attempt to classify agricultural instruction solely on the basis of the fundamental sciences.

A thorough grounding in the natural sciences is confessedly essential to thorough agricultural courses; but so long as the instruction is confined to the departments of pure science it has had and will have very little significance or importance to agriculture. The teaching of the sciences in their relation and applications to agriculture requires a broad outlook and a special point of view which the teacher of general science rarely if ever possesses. It requires sympathetic relations with the various natural sciences, as well as with the practice of agriculture, for the problems are so complicated that they overstep the boundaries of any single primary science.

Agricultural chemistry, like agriculture, is a composite, and it makes use of scientific facts outside the domain of chemistry. It thus calls for broader interests and relationships, and for the special ability to marshal the facts of general science and apply them to the solution of agricultural problems. Analyze and separate it into the primary sciences to be taught separately and independently by the various departments, and we have destroyed the whole significance and application of this knowledge as far as agriculture is concerned. Either the various departments of science must do just what agricultural chemistry has been doing—lap over into the adjoining sciences and gather data to help explain certain principles and phenomena, or the student must be left to work out these things for himself—an impossible task.

The case is no simpler with investigation. The attempt of the botanist to work out the theory of plant nutrition would at once lead him over into the fields of chemistry and other branches of science, with which he must needs form a combination quite as essentially a "bastard" as Doctor Thiel declares agricultural chemistry to be. It is the complicated character of problems of the soil, of crop production, animal nutrition, dairying, etc., which calls for specialists who are not confined to the limits of a single science, and which has developed special methods of investigation.

If the divisions of science were strictly adhered to we should have no such thing as agricultural science, no systematic attempt to bring together and classify scientific knowledge in its relations to agriculture, and no scientific basis for agricultural instruction. The composite character of agricultural chemistry and its special point of view are the very traits which give it its great usefulness and make its continued recognition extremely desirable from the standpoint of both instruction and investigation. It has blocked out a special field, which with the further classification of agriculture will doubtless need to be more carefully defined but not eliminated.

The classification of agriculture is no easy task, but it is not to be accomplished by reverting to the basis of the primary sciences. This much we have learned from the experience of the past. Any system which refers the instruction in agriculture to the departments of pure science, even with agricultural specialists in those departments, will fail of efficiency on account of the restricted scope and the special view point imposed by the individual departments. The facts of pure science and the conditions of agricultural practice must be brought together and harmonized. This can not be left to the agricultural student or to the educated farmer.

The present-day plan for the classification of agricultural knowledge and its formulation into courses of instruction has cut loose entirely from the old academic idea. It is based on the application of this knowledge in the natural divisions of agriculture, rather than on its scientific origin. In a large measure it obliterates for its purpose the boundary lines of pure science. We have long since ceased to teach the subject of soils under the head of geology, and are beginning to group the teaching of the theory and practice of crop production into a department of agronomy. This seems to be a fairly logical and workable basis for the arrangement of teaching courses, and a proposal to return to the former basis of the primary sciences would find scant indorsement among men who have studied the pedagogics of agriculture. It would seem, moreover, to have little support in the courses pursued in other special branches of education.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Chemistry and Canadian agriculture, F. T. Shutt (*Science, n. ser., 26 (1907), No. 661, pp. 265–276*).—This is the address of the chairman of the section of agricultural chemistry at the Toronto meeting of the American Chemical Society, reviewing the climatic and soil conditions of the different provinces of the Dominion of Canada and the chemical work which has been done under the author's direction in the laboratory of the Central Experimental Farm at Ottawa, more particularly on the relation of organic matter and nitrogen to the crop producing power of soils. The article includes data relating to the nitrogen content of various leguminous plants, the increase of soil nitrogen due to the growth of such plants, and the evidence of soil enrichment from subsequent crop yields.

Progress in agricultural chemistry during 1906, A. Stutzer (*Chem. Ztg., 31 (1907), Nos. 43, pp. 547–549; 44, pp. 561, 562; abs. in Chem. Zentbl., 1907, II, No. 5, p. 424*).—This is a review of the principal reports of investigations (mainly German) during the year on soils, nutrition of plants, fertilizers, feeding of animals, feeding stuffs, soil bacteriology, and analytical methods.

The constitution of the alkali salts of phenolphthalein and the behavior of phenolphthalein toward alkali solutions of high concentration, B. M. Margosches (*Ztschr. Angew. Chem., 20 (1907), Nos. 5, pp. 181–191; 6, pp. 226–231*).—It is shown that with an excess of highly concentrated alkali solution colorless alkali combinations of phenolphthalein are formed.

A new method for the determination of ammonia, A. Ronchèse (*Jour. Pharm. et Chim., 25 (1907), pp. 611–617; Bul. Soc. Chim. France, 4. ser., 1 (1907), No. 16–17, pp. 900–905; abs. in Analyst, 32 (1907), No. 377, p. 303; Jour. Chem. Soc. [London], 92 (1907), No. 538, II, p. 651; Ann. Chim. Analyt., 12 (1907), No. 9, pp. 366, 367*).—The method described is based upon Delèpine's observations that formaldehyde reacts with ammonium chlorid to form hexamethylene-tetramine, and that if the formaldehyde is in excess all of the acid of the ammonium salt is liberated and may be titrated with standard alkali (tenth-normal sodium hydroxid) using phenolphthalein as indicator.

Methods of estimating the metabolism of nitrogen in subjects in health and disease, M. and H. Labbé (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 16, pp. 826–828*).—From a series of determinations by the Kjeldahl method, the Regnard urea method, and the Mörner method for total nitrogen and urea nitrogen, the conclusion is reached that the first-mentioned method is superior, as the others give too low results.

The determination of potash by the platinum chlorid method, H. J. F. de Vries (*Chem. Weekbl., 4 (1907), pp. 231–242; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 536, II, p. 504*).—"The causes of error in the estimation of potassium by the platinum chlorid method are discussed, and the author's views as to the best means of avoiding them are stated. A summary of work on this subject is given."

The determination of potash and soda in feldspar, G. Dillner (*Jern-Kontorets Ann., 62 (1907), p. 147; abs. in Chem. Ztg., 31 (1907), No. 54, Repert. No. 49, p. 324*).—A slightly modified Lawrence Smith method is described and recommended.

Contribution to the determination of phosphoric acid volumetrically, W. D. Richardson (*Jour. Amer. Chem. Soc., 29 (1907), No. 9, pp. 1314, 1315*).—In view of the inaccuracy of results obtained by the Pemberton volumetric method in the case of superphosphates, the author undertook some investigations which indicated that the error in this case was due to the presence of sulphuric acid. He therefore proposes a method in which the sulphuric acid is precipitated as barium sulphate before the phosphoric acid is determined.

The determination of citric-acid soluble phosphoric acid in Thomas slag, P. Wagner, R. Kunze, and W. Simmermacher (*Landw. Vers. Stat., 66 (1907), No. 4-5, pp. 257-284; abs. in Chem. Ztg., 31 (1907), No. 58, Repert. No. 53, p. 351; Jour. Chem. Soc. [London], 92 (1907), No. 537, II, p. 577*).—This article describes and discusses 5 methods which are believed to give reliable results when carried out strictly according to the directions given in the article. These are the German official method (separating silica by evaporation with hydrochloric acid), the Darmstadt method (separating silica by heating with magnesium citrate mixture), the Naumann method, the molybdic method, and the Lorenz method.

The results obtained by direct precipitation agree with those obtained by the methods named only when the slag extract gives no, or only slight, reaction by the Kellner test.

Of the 5 methods the molybdic method requires greatest care. Then follows the official method (with separation of silicic acid by means of hydrochloric acid), Naumann's method, Lorenz's method, and the Darmstadt method.

The Lorenz method is not suited to routine laboratory work. The results are accurate, but the method requires much attention to details. The unavoidable nitric acid fumes are disagreeable and the weighing of the hygroscopic precipitate must be done with care.

Although the official method with direct precipitation in extracts giving no reaction by the Kellner test yields reliable results, it is recommended that in all cases silicic acid be precipitated by heating with citrate of magnesia mixture and the phosphoric acid precipitated by addition of ammonia to the filtrate. This method, which is designated the Darmstadt method, is as follows:

To 100 cc. of the citric-acid extract of the slag in a 200 cc. flask add 50 cc. of a citrate of magnesia mixture prepared by dissolving 2 kg. of citric acid and 400 gm. of ammonium chlorid in 2 liters of water, adding 5 liters of 20 per cent ammonia, cooling, adding 550 gm. of magnesia chlorid, and making the volume to 10 liters with water. Heat gently, for about 15 minutes, over a small Bunsen burner flame, until the silicic acid separates out. Swing the flask a few times in order to collect the silicic acid in a mass, and heat over a strong flame to the boiling point. Cool, add 25 cc. of hydrochloric acid of 1.124 sp. gr., and allow to stand for one-half hour. Swing the flask twice during this time. Fill the flask with water, close with a rubber stopper, and shake repeatedly and vigorously until the silicic acid floccules are finely divided. Filter, and to 100 cc. of the filtrate (corresponding to 0.5 gm. substance) add 50 cc. of 10 per cent ammonia and stir for one-half hour in a Stutzer apparatus.

The method is recommended as accurate and well adapted to routine laboratory work.

Determination of nitric acid in the soil, S. Frankfurt and A. Dushechkin (*Vyestnik Sakh. Promuish., 1906, No. 44, pp. 652–660; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 2, p. 250; Chem. Abs., 1 (1907), No. 17, p. 2285*).—The conclusions of the authors are as follows: (1) The hitherto accepted method of determining nitric acid in soils by digesting the soil with water during 48 hours gives results considerably too low; (2) two-hour digestion is sufficient to extract the nitric acid from the soil. Longer contact of water with the soil renders the use of chloroform or other similar agent necessary.—P. FIREMAN.

The obtaining of the soil solution in unaltered condition, V. Ischerekov (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 2, pp. 147–166*).—The method proposed consists in the displacement of the aqueous soil solution by another liquid, such as ethyl or methyl alcohol. The soil is placed in a glass tube covered at the bottom with closely woven linen and the alcohol is poured over it; after some time, the length of which depends on the height of the alcohol column and the degree of saturation of the soil, the aqueous solution begins to flow out through the linen filter. When a layer of half a centimeter of alcohol was poured on a saturated soil drops of liquid began at once to flow through the linen. With a layer of 10 to 15 cm. of alcohol there was a steady flow of drops of the aqueous solution. With a soil containing, for example, 24 cc. of water, about 23 cc. of clear aqueous solution was obtained before the outflowing liquid showed any turbidity indicating admixture of alcohol. The aqueous solution was perfectly transparent, without any traces of turbidity or precipitate, but slightly colored yellow by the humus matter. In case of soils with varying degrees of humidity, and especially with sandy soils, it was found necessary to pack the soil in the tube in order to prevent the flowing of the alcohol through free passages.

In experiments described by the author 100-gram samples of a sandy soil received, respectively, 10 cc. and 20 cc. of water and the aqueous solution was displaced by alcohol. The hygroscopic moisture of the soil was 0.41 per cent; hence there was in one sample 10.41 cc. and in the other 20.41 cc. of water. In the former case 8 cc. and in the latter 16.5 cc. of aqueous solution was obtained. Seven cubic centimeters of the first solution and 10 cc. of the second were evaporated and the residue dried at 105° C. The residue from the 7 cc. was 0.0261 gm., indicating 0.0388 gm. of dissolved substances in the 100 gm. of the soil. The residue from the 10 cc. was 0.0187 gm., indicating 0.0382 gm. of dissolved substances in 100 gm. of soil. Thus the addition of more water did not perceptibly increase the salt content of the solution.

In another experiment 300 gm. of a sandy soil received 53 cc. of water. The outflowing solution was collected in separate portions. Portion 1 contained 15 cc., portion 2, 20 cc., and portion 3, 17 cc., the last portion being quite turbid and mixed with alcohol. The entire first portion and an equal amount of the second were evaporated and dried at 105° C. There were obtained, before ignition, from portion 1, 0.0411 gm., and from portion 2, 0.0425 gm., and after ignition, from portion 1, 0.0086 gm., and from portion 2, 0.008 gm. In the third portion the salt content was greatly reduced by alcohol.—P. FIREMAN.

The interaction between minerals and water solutions with special reference to geologic phenomena, E. C. Sullivan (*U. S. Geol. Survey Bul. 312, pp. 69*).—This bulletin reports work undertaken in the chemical laboratory of the U. S. Geological Survey "in an attempt to apply chemical methods to the investigation of geologic processes and especially of the secondary deposition of ores," accompanied by an outline of earlier work along this line on filtration and diffusion and chemical reaction.

The method of procedure in the experimental work was in general as follows: "The mineral, finely ground in an agate mortar, was left several days at room temperature, with occasional shaking, in a well-stoppered flask with twice its weight of the solution. Whether contact was for a few hours or a few months made little difference. The liquid was filtered through a double layer of filter paper in a Gooch crucible, which, except in the case of pure-water extracts, retained the finest powders and gave perfectly clear filtrates. A measured quantity of the filtrate was subjected to analysis. After addition of acid, silica was removed by evaporation, iron and aluminum were precipitated with ammonia, and calcium was separated with ammonium oxalate. Ammonium salts were then driven off by heating, and magnesium was precipitated and washed with barium hydroxid solution and weighed as the sulphate. The barium hydroxid contained a trace (less than 0.1 per cent) of impurity, chiefly potassium and sodium, for which a correction was applied in the one or two cases in which it was of significance. In the filtrate from magnesium hydroxid barium was precipitated with ammonium carbonate, reprecipitated, and the alkalis in the filtrate were weighed as chlorids and separated in the usual way. Repeated tests of the alkali chlorids for magnesium gave, as a rule, an unweighable trace at most—rarely a few tenths of a milligram."

The determination of numic acid in soils, G. H. Coops (*Chem. Weekbl. 4 (1907), pp. 315–321; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 537, II, p. 590*).—The method employed was as follows: Boil about 10 gm. of the soil repeatedly with absolute alcohol, recovering the bulk of the alcohol by distillation and restoring the original volume by addition of water (Fresenius's method). Filter off the solution containing the soluble humic acids from the waxy and resinous matters and titrate with tenth-normal barium hydroxid.

"The precipitate formed, which may be converted into barium sulphate, represents those humic acids which form insoluble barium compounds. The filtrate on addition of sulphuric acid yields a further quantity of barium sulphate representing soluble barium salts of humic acids. The residue from the alcoholic extraction contains other humic acids. It must be remarked, however, that humic compounds are present, which under the influence of alkalis gradually yield additional humic acids."

Heat the mass with addition of a little water on the water-bath for half an hour, with careful addition of tenth-normal potassium hydroxid until neutral. Filter the solution and wash the residue a few times (this is much assisted by centrifugal action), and then digest with an equivalent amount of tenth-normal sulphuric acid, uniting the two extracts. As a check, mix one-half of the solution with a saturated solution of potassium sulphate, thus precipitating certain humic acids, and titrate the filtrate with tenth-normal potassium hydroxid. Shake the other half well with ether, which removes any colloidal silica as an emulsion. After submitting to centrifugal action siphon off the bottom layer and divide it into three portions. Mix one of these with a saturated solution of potassium sulphate, and titrate the filtrate with tenth-normal potassium hydroxid. Titrate the second portion with tenth-normal barium hydroxid. Convert the soluble and insoluble barium salts formed into sulphate and weigh. Carefully neutralize the last portion with tenth-normal potassium hydroxid and precipitate with ferrous ammonium sulphate, collecting and weighing the precipitate, which, allowing for the iron oxid contained therein, represents gallic acid derivatives. Finally calculate all results on air-dry and ash-free soil.

Extracting with citric acid as a means of determining the fertility of soils, S. Frankfurt and I. Novikov (*Vyestnik Sakh. Promuish., 1906, Nos. 46, pp. 721–726; 47, pp. 758–765; 48, pp. 801–808; 49, pp. 838–846; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 2, pp. 249, 250*).—

The authors describe numerous investigations which lead them to the conclusion that the application of weak acid extractions in general and of citric acid extraction in particular as a means of determining the fertility of soils and of their responsiveness to fertilizers, does not have sufficient basis.—P. FIREMAN.

Determination of carbon dioxid, W. H. WAGGAMAN (*Abs. in Science, n. ser., 26 (1907), No. 660, p. 244*).—This is an abstract of a paper read before the Toronto meeting of the American Chemical Society, giving an account of a modification of an apparatus previously described by Cameron and Breazeale and of results obtained with it on a number of organic compounds and carbonate minerals.

The determination of nitrogen in water by elementary analysis, M. RUBNER (*Arch. Hyg., 62 (1907), No. 1, pp. 83-91*).—As a result of tests of this method the author proposes as a substitute for it a colorimetric modification of the Kjeldahl method.

A rapid method for the determination of calcium in water, and its significance in connection with the analysis of water for boiler purposes, F. E. HALE (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 1078–1085*).—The method proposed is an adaptation of the old and standard method based upon the precipitation of the calcium as oxalate, the decomposition of the calcium oxalate with sulphuric acid, and the titration of the liberated oxalic acid with potassium permanganate. It is claimed that the modified method is very accurate and gives a complete analysis in 30 minutes.

"The method is admirably suited for the routine analysis of large numbers of samples, may be considered accurate to 2 parts per million, is applicable to all quantities of calcium including that of sea water, is equally accurate with large and small quantities of calcium, furnishes, in combination with the soap method, a rapid method of determining the total magnesium, and hence is extremely valuable in the rapid analysis of mineral and boiler waters."

Determination of the hardness of water, P. NAWIASKY and S. KORSCHUN (*Arch. Hyg., 61 (1907), No. 4, pp. 348–354; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 537, II, p. 579*).—The authors recommend and describe Pfeiffer's methods for temporary and total hardness and Monhaupt's method for magnesia.

The determination of manganese in water, R. S. WESTON (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 1074–1078*).—The author describes and recommends a modification of Schneider's method, which is based upon the fact that in the presence of an excess of nitric acid a manganous salt is oxidized to permanganic acid by bismuth tetroxid.

Swiss food book (*Schweizerisches Lebensmittelbuch. Bern, 1906, 2. rev. ed., pt. 3, pp. IX+95; rev. in Hyg. Rundschau, 17 (1907), No. 17, pp. 1053–1055*).—Official methods for the examination of meat and meat products, legumes and products made from them, bread and other flour products, spices, coffee and coffee substitutes, tea, cocoa, and chocolate.

Food inspection methods of analysis (*Jour. Off. Répub. Franc., 39 (1907), No. 193, pp. 5032–5034*).—Official methods are given for the examination of cider, perry, flour, and meal, for the detection of tin in cakes and molasses, and for the detection of preservatives and artificial sweetening substances.

Preserved vegetables containing copper and its estimation, C. BREBECK (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 9, pp. 548–552*).—In the method which the author outlines for determining copper in vegetables, the material is incinerated, evaporated with hydrochloric acid, treated with ammonia, and the copper precipitated in a platinum dish by inserting a strip of pure zinc. He states that metallic copper adheres firmly to the platinum.

The water found in the cans of preserved vegetables, according to the author, contains no copper, even when large amounts are found in the vegetables themselves, and the same is true of the vinegar from pickles containing copper. It is his custom to disregard such liquid in determining copper.

The guaiac reaction for determining the quality of flour, A. Corsini (*Riv. Ig. e Sanit. Pub.* [*Rome*], *16* (*1906*), *No. 19; abs. in Hyg. Zentbl.*, *2* (*1907*), *No. 22, pp. 689, 690*).—The value of the guaiac reaction for judging the quality of flour is insisted upon and data regarding its use are reported.

Some experiments on the oxidation of flour and milk, A. Corsini (*Arch. Farmacol. Sper. e Sci. Aff.*, *6* (*1907*), *No. 6, pp. 357–362*).—This work covers much the same ground as that noted above.

The behavior of wheat and rye flour to methylene blue and to starch paste, with notes on the formation of higher alcohols, F. Schardinger (*Centbl. Bakt.* [*etc.*], *2. Abt.*, *18* (*1907*), *No. 24–25, pp. 748–767, fig. 1*).—Differences in behavior of the two sorts of flour to methylene blue and to starch paste at a given temperature were noted. Notes are included regarding micro-organisms which form higher alcohols from flour.

A source of error in the use of petroleum ether for fat extraction, J. Marshall (*Amer. Jour. Pharm.*, *79* (*1907*), *No. 7, pp. 315–317*).—In a commercial petroleum ether derived from the Pennsylvania oil field the writer found an appreciable quantity of residue after distilling and evaporating, which makes it "evident that a petroleum ether of this sort is not adapted for use in making extractions." Residue was also obtained from commercial "ethyl ether distilled over sodium."

Experiments on the Maumené test and the iodin value of certain oils. E. Richter (*Ztschr. Angew. Chem.*, *20* (*1907*), *No. 37, pp. 1605–1614, figs. 3, dgms. 4*).—Different forms of apparatus for use in carrying on the Maumené test are described and results of studies with rape seed, poppy, peanut, and olive oil and mixed oils are reported.

Report on the work of the agricultural chemical control station of Saxony, 1906, H. C. Müller (*Ber. Agr. Chem. Kontrollstat. Halle, 1906, pp. 47*).—A brief account is given of the personnel of the station and the very extensive control work done during the year, which included the examination of 38,930 samples of various products, including 8,075 samples of fertilizers, 2,214 samples of feeding stuffs, 22,776 samples of milk and dairy products, and 4,877 samples of seed, besides various other miscellaneous materials.

Unification of terms used in reporting analytical results, C. G. Hopkins (*Jour. Amer. Chem. Soc.*, *29* (*1907*), *No. 9, pp. 1312–1314; abs. in Science, n. ser.*, *26* (*1907*), *No. 660, p. 249*).—This is an abstract of a report presented at the Toronto meeting of the American Chemical Society embodying the recommendations which had already been made to the associations of Official Agricultural Chemists and of American Agricultural Colleges and Experiment Stations (E. S. R., 18, p. 415).

A new shaking device for the chemical laboratory, J. M. Camp (*Jour. Amer. Chem. Soc.*, *29* (*1907*), *No. 8, pp. 1210, 1211, pl. 1*).—The apparatus described "consists of a frame supporting a vertical shaft, which is revolved by a six-inch pulley wheel. The upper part of the shaft is bent slightly from the perpendicular. Encircling the bent portion of the shaft is a hub which in turn supports a flat disk on which the flasks to be shaken are attached. The hub and disk are prevented from turning, when the shaft is revolved, by suitable teeth on the under side of the hub meshing into corresponding teeth on the top of the supporting frame." The apparatus gives a pitching and tossing motion which is said to be very effective for the purpose intended.

Apparatus for use in determinations of the fat content in cream, butter, margarin, etc., Wendler (*Milch Ztg., 36 (1907), No. 35, pp. 410, 411, figs 6*).—The author describes a modification of the test flasks used in the Gerber butyrometer, whereby "a quicker and more convenient, and, therefore, more exact reading" of the proportion of fat in the sample is possible.

METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev., 35 (1907), Nos. 7, pp. 303–334, figs. 5, charts 7; 8, pp. 345–388, figs. 2, charts 6*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of July and August, 1907, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 7.—The Fundamental Interval in Meteorological and Climatological Studies, especially in Charts of Isohyetal Lines; A Possible Case of Ball Lightning (illus.), by W. H. Alexander; Studies on the Phenomena of the Evaporation of Water over Lakes and Reservoirs, by F. H. Bigelow; Tornado at Parkersburg, W. Va.; Australian Climatology (illus.); Electric Spark Produced When Ice is Formed; The Jamaican Weather Service (illus.), by D. T. Maring; and Interesting Lunar Corona, by C. M. Hammond.

No. 8.—Influence of Temperature and Moisture upon the Rate of Growth of Tobacco (illus.), by G. N. Coffey; Studies of Frost and Ice Crystals, by W. A. Bentley; Cottier's Resistance of Elastic Fluids; A Summary of the History of the Resistance of Elastic Fluids (illus.), by J. G. C. Cottier; Local Forecasting at Escanaba, by W. P. Stewart; Lightning Phenomena, by I. Langmuir; Salton Sea and Local Climate; Tornado at Maple Plain, Minn.; Hail Shooting in Italy; Influence of the Glass Cover on Actinometric Thermometers, by L. Gorczynski, trans. by R. A. Edwards; Report on the Great Indian Earthquake of 1905, by C. F. Marvin; and The New Public Weather Service of Germany, by P. Polis, trans. by G. E. Rausch.

Meteorological observations, J. E. Ostrander and T. A. Barry (*Massachusetts Sta. Met. Buls. 225, 226, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during September and October, 1907. The data are briefly discussed in general notes on the weather of each month.

The climate and soils of the Panhandle area [of West Virginia], G. P. Grimsley, T. A. Caine, and G. W Tailey, Jr. (*W. Va. Geol. Survey, County Rpts. 1906, pp. 308–366, figs. 10, map 1*).—The chapter on climate summarizes the meteorological observations made at Wheeling since 1876, at Highland Springs near Wellsburg since 1890, and at New Cumberland since 1901.

The chapter on soils is a report of a survey made by the Bureau of Soils of this Department and published elsewhere in this issue (p. 417).

Mt. Rose Weather Observatory, 1905–1907, J. E. Church, Jr. (*Sierra Club Bul., 6 (1907), No. 3, pp. 177–185, pls. 4*).—This is an illustrated account of this observatory, which has already been referred to (E. S. R., 18, p. 529.)

Annual report of the director of the [Philippine] Weather Bureau for the year 1904, J. Algué (*Ann Rpt. Philippine Weather Bur., 1904, pt. 3, pp. 562*).—This third part of the annual report of the director of the Philippine Weather Bureau gives detailed tabular summaries of meteorological observations of the secondary stations in the Philippine Islands during 1904.

Rainfall conditions of South America, E. L. Voss (*Mitt. Justus Perthes' Geogr. Anst., 1907, Engänzungsh. 157, pp. V+59, charts 19, dgm. 1*).—The available data are summarized and charted with reference to amount and daily, monthly, seasonal, yearly, and regional distribution.

Work of the central meteorological bureau in 1906, J. J. A. Bouquet de la Grye (*Bul. Mens. Off. Renseig. Agr.* [*Paris*], *6* (*1907*), *No. 7, pp. 827–832*).—This article summarizes the work of the bureau during the year on climatology and general meteorology throughout France, as well as in Algeria and Tunis, and describes briefly the improvements in equipment of various local observatories, the functions of the meteorological commissions of the different departments of France, and the progress made in France and abroad in the investigation of the cause and possible prevention of hail.

The climate of São Paulo, J. N. Belfort de Mattos (*Bol. Agr.* [*São Paulo*], *8. ser., 1907, No. 6, pp. 260–264*).—This is a brief general description of the main climatic features of the region.

Correlation of the weather and crops, R. H. Hooker (*Jour. Roy. Statis. Soc., 70* (*1907*), *No. 1, pp. 1–51*).—In amplification and extension of the ideas advanced by W. N. Shaw (E. S. R., 18, p. 713), the author calculates the correlation coefficients between rainfall and temperature of various periods and the yield of wheat, barley, oats, peas, beans, potatoes, turnips, ruta-bagas, mangel-wurzels, and hay in a selected area, consisting of the counties of Lincoln, Huntingdon, Cambridge, Norfolk, Suffolk, Essex, Bedford, and Hertford, England. In tracing the relation between rainfall and crop yields he assumes that the maximum coefficient indicates the period of greatest influence, and on this basis discusses in detail the figures obtained for each of the individual crops.

The discussion following the reading of this paper indicated the prevalence of the opinion that the data presented were suggestive rather than conclusive, but that such papers as this and those by Shaw open up a new and very promising field of investigation.

Precipitations, their income and outgo in relation to droughts, M. Neruchev (*Zap. Imp. Obshch. Selsk. Khoz. Yuzh. Ross., 1906, No. 4–6; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8* (*1907*), *No. 1, pp. 119, 120*).—The author attributes the droughts in Southern Russia, not so much to deficiency of precipitation as to excessive loss of the moisture, mainly through evaporation. He quotes different investigators, from which it appears that in Southern Russia the evaporation not only absorbs the entire precipitation, but considerably exceeds it. If this is the case, the question arises, from what source does the plant derive its water supply? To this Professor Klossovski gives the following answer: The losses of water in the form of evaporation are compensated by the power, not only of the soil, but also of the rock species to condense in their pores considerable quantities of water absorbed from the atmosphere. The atmospheric moisture is absorbed by the soil, and compensates the losses by evaporation. This being the case, it would seem that severe droughts in Southern Russia are due to the unproductive expenditure of the soil moisture through excessive surface run-off in case of torrential rains and, in the author's opinion, in part to imperfect absorption by the soil, due to shallow plowing.—P. FIREMAN.

Deficient humidity of the atmosphere, T. A. Starkey and H. T. Barnes (*Proc. and Trans. Roy. Soc. Canada, 2. ser., 12* (*1906*), *Sec. III, pp. 203–211*).—The injurious effects of excessive dryness in the air of houses and means of overcoming such unfavorable conditions are described.

International catalogue of scientific literature. F—Meteorology (*Internat. Cat. Sci. Lit., 5* (*1907*), *pp. VIII + 283*).—This is the fifth annual issue of this catalogue, covering mainly the literature of 1905, but also including some references to the literature of 1901 to 1904 omitted from previous issues.

Surface water supply of [different regions of the United States], 1906 (*U. S. Geol. Survey, Water-Supply and Irrig. Papers Nos. 202, pp. 77, pls. 2,* *figs. 2; 203, pp. IV + 100, pls. 4, figs. 2; 204, pp. V + 110, pls. 5, figs. 2; 205, pp. 123, pls. 3, figs. 2; 206, pp. VI + 98, pls. 3, figs. 2*).—These bulletins contain reports in the usual form on the progress of stream measurements in the Hudson, Passaic, Raritan, and Delaware River drainages, by H. K. Barrows, N. C. Grover, et al.; Middle Atlantic States, by N. C. Grover et al.; Southern Atlantic and Eastern Gulf States, by M. R. Hall et al.; Ohio and Lower Eastern Mississippi River drainages, by M. R. Hall, N. C. Grover, A. H. Horton, et al.; and Great Lakes and St. Lawrence River drainages, by H. K. Barrows, A. H. Horton, et al. The methods employed in making the measurements are briefly explained.

Fresh water, K. KNAUTHE (*Das Süsswasser. Neudamm, 1907, pp. VIII+663, figs. 194*).—In this volume the author has summarized a large amount of data on water analysis, the relation of water to fish culture, flora and fauna of fresh water, the value of different waters as food for marine life, and water bacteria and ferments. The volume as a whole constitutes a handbook on fresh water with special reference to its utilization for fish culture and related topics. Author and subject indexes are provided.

The use of ice on the farm, J. A. RUDDICK (*Canada Dept. Agr., Branch Dairy and Cold Storage Comr. Bul. 20, pp. 8, fig. 1*).—"This bulletin is intended to encourage the practice of providing a supply of ice for the needs of the household and the dairy, and to furnish information to those who may not have had any experience in the storing and handling of ice."

Water—a hydrologic study, E. A. MARTEL (*L'Eau—Étude Hydrologique. Paris, 1906, pp. 87–200, figs. 22*).—This is one part of a general treatise on hygiene, and treats the subject of water mainly from the standpoint of potability. Potable water is defined as that which is clear, fresh, pure chemically and bacteriologically, and may be drunk with pleasure and without danger to health.

The conditions which render it so difficult, if not practically impossible, to secure water supplies measuring up to this high standard, and the best means of insuring the highest possible quality, are quite fully set forth in the various sections of the article dealing with the circulation of subterranean water and the sources and means (sanitary and legal) of prevention of contamination of water. The sanitation and water supply of Paris receives special attention.

In judging of the quality of subterranean waters it is considered of prime importance to know whether they are drawn from smaller interstices or from fissures and other large underground channels. The nature and importance of this distinction is explained at some length with numerous illustrations and examples, and the author's classification of subterranean water is based upon it. A detailed description of the qualities constituting a good water is given.

The principles of water purification, L. M. WACHTER (*Proc. Ann. Conf. Sanit. Off. N. Y., 6 (1906), pp. 105–112*).—The principles of precipitation, sedimentation, and filtration as means of purifying water are briefly explained.

Direct and indirect methods of electrical purification of water, H. LEFFMANN (*Jour. Franklin Inst., 164 (1907), No. 3, pp. 205–216, figs. 5*).—A few of the electrical processes proposed for the removal of mineral impurities or for destroying micro-organisms are described.

The economical purification of sewage in rural districts, T. A. STARKEY (*Brit. Med. Jour., 1907, No. 2437, pp. 671–673*).—This article discusses especially the disposal of sewage by decomposition in a septic tank and oxidation in a filter bed or by irrigation.

The nature of sewage and its proper disposal, J. A. AMYOT (*Proc. Ann. Conf. Sanit. Off. N. Y., 6 (1906), pp. 113–123*).—Various sources of pollution of streams are briefly described, and sewage disposal by means of broad irrigation, intermittent sand filtration, contact beds, sprinkling or continuous filters, with preliminary or auxiliary treatment by sedimentation, septic tanks, and aeration are explained.

SOILS—FERTILIZERS.

The moisture equivalents of soils, L. J. Briggs and J. W. McLane (*U. S. Dept. Agr., Bur. Soils Bul. 45, pp. 23, pl. 1, fig. 1*).—Moisture equivalent is defined as "the percentage of water retained by a soil, when the moisture content is reduced by means of a constant centrifugal force until it is brought into a state of capillary equilibrium with the applied force," i. e., until the water held in the larger capillary spaces is removed.

The centrifugal machine devised for the work is described and the results of preliminary studies of various factors—duration of test, initial water content, speed, etc.—upon the accuracy of the determinations are reported.

The method adopted and used in the determination of the moisture equivalents of over 100 samples of soils is essentially as follows: "The soils under investigation are first thoroughly moistened, and are then placed in the perforated cups of a centrifugal machine, where they are subjected to a constant centrifugal force until they cease to lose moisture. The percentage of water remaining in the soil is then determined."

It is held that by this means it is possible to reduce the moisture content of a soil until it is no greater than the moisture content of the soil under favorable field conditions, and thus to determine the retentive power of different soils for moisture when acted upon by the same definite force, comparable in magnitude with the pulling force to which the soil moisture is subjected in the field. "Furthermore, this method of comparing the relation of soils to moisture avoids to a large extent, if not entirely, the errors due to differences in packing, since the soils are packed by centrifugal force, which acts upon each individual particle. This is further safeguarded by the high speed employed, which is sufficient to remove the moisture from any large capillary spaces that may possibly be formed. . . .

"A series of soils which have thus been brought into equilibrium with the same force will be in capillary equilibrium with one another when brought into contact, and no capillary movement of moisture will take place between them. In other words, the moisture equivalents of a series of soils represent the moisture contents which those soils must have in order to make it equally difficult to remove a very small additional amount of moisture from any of the soils. It is from this point of view that the determination of the moisture equivalent becomes of special importance in the comparison of the moisture contents of different soils under growing crops."

The moisture equivalents of over 100 samples of type soils, using a centrifugal force about 3,000 times the force of gravity, were found to vary from 3.6 per cent in the coarser sandy soils to 46.5 per cent in the case of a heavy clay subsoil.

When "these observations were reduced by the method of least squares to determine the influence of the sand, silt, and clay groups, and of the organic matter, upon the retention of moisture, it was found for the whole series that each per cent of clay or organic matter in the soil corresponded to a retention of 0.62 per cent of moisture when the soil was subjected to a force 3,000 times that of gravity. Each per cent of silt, under similar conditions, corresponded to a retention of 0.13 per cent of moisture, and the coarser grades show practically no retentive action against this force. The 'probable error' for these coefficients was rather high, and better results were obtained for smaller series of related soils, using a different set of coefficients. It is interesting to note that the organic matter, for the force employed, has a retentive power no greater than the clay group.

"In investigating the influence of the speed upon the moisture equivalent it was found, for the series of soils examined, that between certain limits the amount of moisture set free when the pulling force is increased by a definite amount is the same for the different soils. In other words, when this series of moist soils is in equilibrium with a given force, and the force is then increased by a definite amount, the amount of water set free is independent of the initial water content. Within these limits, then, a sandy soil and a heavy soil of this series part with equal amounts of moisture."

Soil fertility, M. WHITNEY (*La Fertilité du Sol. Montpellier, 1907, pp. 52, figs. 2*).—A French translation of Farmers' Bulletin 257 of this Department (E. S. R., 18, p. 119), by H. Fabre, of the National School of Agriculture of Montpellier.

Field operations of the Bureau of Soils, 1905 (seventh report), M. WHITNEY ET AL. (*U. S. Dept. Agr., Field Operations of the Bureau of Soils, 1905, pp. 1089, pls. 2, figs. 45, maps 47*).—This report contains a general review of the work of the Bureau of Soils during 1905, by the Chief of the Bureau, together with detailed accounts of the following surveys:

Tompkins county, N. Y., by J. A. Bonsteel, E. O. Fippin, and W. T. Carter, jr.; the Binghamton area, N. Y., by E. O. Fippin and W. T. Carter, jr.; Montgomery county, Pa., by H. J. Wilder, A. T. Strahorn, and W. J. Geib; Chester county, Pa., by H. J. Wilder, T. A. Caine, W. J. Geib, and W. T. Carter, jr.; Upshur county, W. Va., by A. M. Griffen and O. L. Ayrs; Louisa and Hanover counties, Va., by H. H. Bennett and W. E. McLendon; the Yorktown area, Va., by R. T. A. Burke and A. S. Root; Perquimans and Pasquotank counties, N. C., by J. E. Lapham and W. S. Lyman; Duplin county, N. C., by A. S. Root and L. A. Hurst; York and Cherokee counties, S. C., by J. A. Drake and H. L. Belden; Spalding county, Ga., by J. E. Lapham, W. S. Lyman, and C. W. Ely; Leon county, Fla., by H. J. Wilder, J. A. Drake, G. B. Jones, and W. J. Geib; Lauderdale county, Ala., by F. E. Bonsteel, O. L. Ayrs, T. D. Rice, and E. P. Carr; Blount county, Ala., by W. G. Smith and F. N. Meeker; Montgomery county, Ala., by W. E. McLendon and C. J. Mann; Dallas county, Ala., by E. P. Carr, W. E. Hearn, H. H. Bennett, and R. T. A. Burke; the Crystalsprings area, Miss., by J. L. Burgess and W. E. Tharp; Tangipahoa parish, La., by A. M. Griffen and T. A. Caine; East Baton Rouge parish, La., by C. W. Ely, H. W. Marean, and N. P. Neill; Houston county, Tex., by W. T. Carter, jr., and A. E. Kocher; the Waco area, Tex., by A. W. Mangum and M. E. Carr; Lee county, Tex., by J. L. Burgess and W. S. Lyman; Lavaca county, Tex., by C. N. Mooney, F. Bennett, A. T. Strahorn, and H. L. Belden; Henderson county, Tenn., by M. E. Carr and F. Bennett; Madison county, Ky., by A. M. Griffen and O. L. Ayrs; McCracken county, Ky., by T. D. Rice; the Cleveland and Westerville areas, Ohio, by J. E. Lapham and C. N. Mooney; the Oxford area, Mich., by G. B. Jones and M. E. Carr; Newton and Tippecanoe counties, Ind., by N. P. Neill and W. E. Tharp; the Carlton area, Minn.-Wis., by W. J. Geib and G. B. Jones; Portage county, Wis., by F. N. Meeker and R. T. A. Burke; Crawford and Scotland counties, Mo., by W. E. Hearn and C. J. Mann; Sarpy county, Nebr., and the Carrington area, N. Dak., by A. E. Kocher and L. A. Hurst; Brown county, Kans., by J. L. Burgess, W. E. Tharp, and W. S. Lyman; the Grand Junction area, Colo., by J. G. Holmes and T. D. Rice; the Gallatin valley, Mont., by M. H. Lapham and C. W. Ely; the Stockton area, Cal., by M. H. Lapham and W. W. Mackie; and Island county and the Everett area, Wash., by E. P. Carr and A. W. Mangum.

During the calendar year 1905, 21,289 square miles, or 13,624,960 acres, were surveyed and mapped on a scale of 1 in. to the mile, making the total area surveyed and mapped up to the end of that year 110,087 square miles, or 70,455,680 acres. The average cost of the field work in 1905 was $2.66 per square mile.

A new feature of the soil surveys beginning with the year 1905 "consists of the presentation of the results of tests made to determine the manurial requirements of the more imporant types. In these cases large samples of soils were collected and sent to the Bureau for testing by the wire-basket method. These large samples were subdivided and different kinds of fertilizing materials, including barnyard manure, chemical fertilizers, and green crops, were applied to various quantities and in different combinations. Upon the different samples thus treated wheat plants were grown and their growth compared with that of similar plants grown upon untreated check samples. The soil survey reports give the results of these determinations. This testing of manurial and fertilizer requirements will be continued on all the principal types and classes of soils in the region where the use of fertilizers or manure is common or is being introduced. In this way the soil survey reports will not only deal with the appropriate selection of characteristic soils for the production of different farm crops, but will also indicate the proper procedure whereby increased yields of the staple crops may be secured. These two problems, adaptation of soil to crop and the maintenance and increase of crop yields, constitute the great agricultural problems of the country."

Economic geology of the Independence quadrangle, Kansas, F. C. SCHRADER and E. HAWORTH (*U. S. Geol. Survey Bul. 296, pp. 74+VI, pls. 6, figs. 3*).—This is a report of a study of this area of about 950 square miles in southeastern Kansas, adjacent to Indian Territory, giving the results of observations on the geology and mineral resources, as well as of incidental studies on soils, agricultural conditions, water supply, etc.

Agrogeological studies, P. TREITZ (*Jahresber. K. Ungar. Geol. Anst., 1905, pp. 198–247*).—A series of studies of soils, water, economic deposits, geological relation, and agricultural condition of various areas of Hungary is reported.

An analytical study of the cultivated soils derived from the schists of Pont-de-Larn, Tarn, A. DELAGE, H. LAGATU, and L. SICARD (*Ann. École Nat. Agr. Montpellier, n. ser., 6 (1907), No. 4, pp. 268–326; 7 (1907), No. 5, pp. 47–65; rev. in Bul. Soc. Nat. Agr. France, 67 (1907), No. 3, pp. 248–259*).—This paper forms a part of a series of memoirs on the constitution and composition of arable soils, already referred to (E. S. R., 17, p. 841).

Two broad general conclusions arrived at from this work are stated as follows: (1) No observations have been made which warrant the belief that epigenic processes go on in cultivated soils. All observations tend to show that soils are the simple products of disaggregation of rocks. (2) All chemical transformation (dissociation and recombination) to which soils are subject, follow the solution of the mineral constituents in different solvents, but principally in water, which takes place in very small but constant proportion and without decomposition of the mineral constituents. The authors' results are discussed in the light of similar work by Cameron and Bell (E. S. R., 17, p. 742), and various practical applications of them in their bearing on cultivation, fertilizing, etc., are explained.

A study of the sabak of Upper Egypt, R. ROCHE (*Bul. Assoc. Chim. Sucr. et Distill., 24 (1907), No. 11, pp. 1533–1537*).—Analyses of this material, which is the saline débris obtained from sites of ancient villages, are reported and its origin, value, and methods of use are discussed. The analyses reported show it to contain about 1 per cent of potash, 0.65 per cent of phosphoric acid, and 0.44 per cent of nitrogen (0.18 per cent in form of nitric nitrogen).

On the composition of the ashes and lapilli ejected by Vesuvius during the period of activity in April, 1906, N. PASSERINI (*Atti R. Accad. Econ. Agr. Georg. Firenze; 5. ser., 3 (1906), No. 4, pp. 374–385*).—Analyses of a number of different samples are reported and discussed with reference to similar studies of other investigators.

Report on progress in geological peat and moor investigations during 1905 (*Jahresber. K. Ungar. Geol. Anst., 1905, pp. 248–272, pl. 1*).—The report deals with the occurrence, composition, etc., of Hungarian deposits.

The utilization of peat land on the Continent (*Jour. Bd. Agr.* [*London*], *14 (1907), No. 3, pp. 146–155*).—Information is given in some detail regarding the classification, composition, and utilization for agricultural and industrial purposes of peat lands, compiled largely from articles in various German journals.

Results of chemical investigations on a series of moor soils from northwest Germany, B. TACKE and A. SPIECKER (*Ztschr. Forst u. Jagdw., 39 (1907), No. 4, pp. 213–229*).—The results of a somewhat detailed chemical study of a large number of samples of moor soils are reported.

The mineral constituents of the soil solutions, F. K. CAMERON and J. M. BELL (*Ann. Ecole Nat. Agr. Montpellier, n. ser., 6 (1907), Nos. 3, pp. 182–240, figs. 3; 4, pp. 241–267, fig. 1*).—This is a reprint of Bulletin 30 of the Bureau of Soils of this Department (E. S. R., 17, p. 742).

Studies on humus formation, II, S. SUZUKI (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1907), No. 3, pp. 419–423*).—A continuation of previous investigations (E. S. R., 18, p. 14) is reported in which it was found that protein, starch, and pentosans, but not fat or cellulose, can produce the black matter of humus and that the restriction of air is very essential to humus formation. An examination of 2 samples of humus showed that the nitrogen was in the form of protein.

Organic nitrogen in Hawaiian soils, E. C. SHOREY (*Hawaii Sta. Rpt. 1906, pp. 37–59, pl. 1*).—This article states briefly the present status of the nitrogen problem as related to agriculture, calls attention to the high content of nitrogen in Hawaiian soils, reviews our present knowledge of soil nitrogen, and gives a preliminary report on studies of the nitrogenous compounds in Hawaiian soils, including solubility of the nitrogenous compounds in various solvents, the ammonia produced on distillation with various basic substances, and the character of the decomposition products of the nitrogenous matter of the soil.

By extraction of a soil rich in nitrogen (0.73 per cent) with 5-per cent caustic soda, precipitating with nitric acid, removing the precipitate, neutralizing the filtrate with soda, and again filtering, there was obtained a neutral filtrate which on concentration to small bulk yielded a small amount of dark flocculent, apparently humin, substance. The filtrate from this on precipitation with silver nitrate or lead acetate and decomposition of the precipitate with hydrogen sulphid gave on concentration a small amount of a soluble crystalline substance which was subsequently demonstrated to be picolin carboxylic acid. The occurrence of this substance in Hawaiian soils is taken to indicate the presence of pyridin compounds, which may exert a poisonous effect upon plants grown on the soils.

Nitrifying power of chernozem soils, influence of various factors on it, and quantity of nitrates in the soil at different seasons of the year, V. SAZANOV (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8 (1907), No. 1, pp. 1–38*).—Russian chernozem soils respond readily to application of superphosphate, but have little or no need of nitrogenous fertilizers. In the spring, however, they do not contain enough nitrate to supply the wants of the strongly growing young plants and a nitrate fertilizer is badly needed. Later the nitrification in the soil is enough.

The author studied the variation of the nitrogen content of the soil during the period of vegetation with a good clayey chernozem soil taken from a sugar beet field on which during the experiments no plants were raised but which was cultivated like the adjoining area under beets. The results show that the nitrate nitrogen content of the surface soil in the spring was actually very small (as low as 1.9 mg. per kilogram of dry soil). In the course of the summer it increased, reaching in July and August a maximum of 41 mg.

From the results of this and similar experiments the author draws the following general conclusions: (1) Timely, rational cultivation of the soil so as best to preserve the humidity greatly furthers the accumulation of nitrates, (2) the nitrification process in the chernozem soils is not at all or very slightly influenced by manuring, (3) the plowing under of straw holds back the nitrification process only during the earlier period, (4) plants sowed and then plowed under for green manuring, including leguminous crops, besides making the soil too dry during harvest time, strongly impoverish it in assimilable nitrate nitrogen. Also, later no beneficial influence of green manuring on the nitrification process has been observed.—P. FIREMAN.

Soil bacteriological investigations, Maassen and Behn (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 33–38*).—This is a general statement regarding the character of the work done along this line at the Biological Institute of Berlin.

On the bacteria of the tubercles of various leguminous plants, Maassen and Müller (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 42–44*).—Observations are recorded which show an increase of from 1,248,000 to 8,960,000 root tubercle bacteria of *Trifolium pratense* in 1 gm. of soil in 4 days. Studies of the character of the tubercles produced on roots of leguminous plants are referred to as leading to the conclusion that these tubercles are abnormal growths of purely pathological nature. Contrary to previous conclusions, the authors are of the opinion, in the light of their recent investigations, that the root tubercle bacterium is botanically identical in all cases although modified somewhat in roots of different plants.

As a result of a large number of experiments with different kinds of leguminous plants the authors reach the conclusion that: (1) The organism of *Pisum sativum* will inoculate *Vicia faba*, *V. sativa*, *V. villosa*, *Lens esculenta*, *Lathyrus sativus*, *L. odoratus*, and *L. silvestris*; (2) that of *Trifolium incarnatum* will inoculate *T. pratense*; (3) that of *Medicago sativa* will inoculate *M. lupulina* and *Melilotus officinalis*; and (4) that of *Lupinus luteus* will inoculate *L. angustifolius* and *Ornithopus sativus*. The organisms of *Phaseolus vulgaris*, *Soja hispida*, *and Robinia pseudacacia* will apparently not inoculate any other plants. The same is probably true of the organisms of *Coronilla varia*, *Onobrychis sativa*, *Anthyllis vulneraria*, *Sarothamnus scoparius*, *Amorpha fruticosa*, *Caragana frutescens*, and *Acacia lophanta*, although these have not been so fully studied as the others.

The bacteria of leguminous plants, L. Lauvray (*Jour. Agr. Prat., n. ser., 12 (1906), No. 44, pp. 549, 550*).—A brief note is given reviewing practical tests of pure cultures of these organisms.

The action of carbon bisulphid on the bacteria of soils, Maassen and Behn (*Mitt. K. Biol. Anst. Land u. Forstw., 1907, No. 4, pp. 38–42*).—The results of plat and pot experiments are briefly summarized, showing a great reduction in the total count of bacteria immediately following treatment with carbon bisulphid but later an unusual increase. Streptothrix organisms were decidedly injured by the treatment, but the peptonizing organisms, especially the *Bacillus mycoides* group, were less affected. Especially resistant were all spore forms.

The action of the carbon bisulphid was more marked in the pots than in the field. The spore count was 1.8 to 3.8 per cent of the total count in the case of the field soil after treatment, but 77 per cent in the case of the pot soil. The bacterial flora of the two were very different after treatment.

In a study of the resistance to carbon bisulphid (1.7 parts per 1,000 of water) of various nonspore-forming bacteria in pure cultures, it was found that the different kinds of bacteria showed great variation in resistance. The tubercle bacteria of peas, *Bacillus ruber-purpureus*, *B. stutzeri*, *Vibrio berolinensis*, and *V. phosphorescens* were quickly killed, generally within 2½ hours. On the other hand, the tubercle bacteria of Robinia, *Bacillus præpollens*, *B. prodigiosus*, *B. pyocyaneus*, *Bacterium coli commune*, *Micrococcus ureæ*, and *Proteus vulgaris* survived the treatment for as much as 4 hours. The staphylococci were very resistant, surviving the treatment for as much as 48 hours. *Azotobacter chroococcum* in pure cultures and in soil extracts was killed in 24 hours by 1.7 parts of carbon bisulphid per 1,000 of water at 20° C. In moist soils impregnated with the fumes of carbon bisulphid it survived 48 hours. The results show in general that the vegetable forms of bacteria are, as a rule, destroyed in 24 hours by carbon bisulphid of the strength given.

In similar studies with the mixed bacterial flora of soils the effect of the carbon bisulphid was at its height at the end of 24 hours, little but the spore forms remaining at the end of this period. At the end of 17 days, however, the bacterial count was nearly the same as before treatment, and in from 17 to 30 days there was an increase.

The effect of desiccation on root tubercle bacteria, F. D. Chester (*Delaware Sta. Bul. 78, pp. 15*).—The results of previous investigations bearing upon the effect of desiccation upon different kinds of bacteria are stated to be very variable and confusing. The results of the author's experiments with cultures of *Pseudomonas radicicola* freshly prepared from root tubercles and dried on cotton or in dishes, and with cultures obtained from the Bureau of Plant Industry of this Department lead to the following conclusions:

"(1) *P. radicicola* has little power to withstand drying, and its preservation in the dry state on cotton is inadvisable.

"(2) Fresh cultures, by containing a larger number of active organisms, are better for inoculating cotton than old cultures.

"(3) Cultures dried on cotton and exposed to atmospheric influences die very rapidly, the great majority of the bacteria perishing during and up to the point of complete desiccation, a few more resistant individuals surviving, and these only for a very limited time.

"(4) With the use of fresh, vigorous cultures, dried quickly on cotton, and kept in sealed bottles, *P. radicicola* will survive for a longer time with certain strains and for only a short period with others; but even this method of preparation, which offers the best conditions for preservation, is uncertain.

"(5) *P. radicicola* when dried in thin films on glass perish very rapidly.

"(6) The latter is also true of *P. radicicola* when dried on seed."

On the action of barnyard manure, J. Stoklasa (*Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 4, pp. 440–471; Fühling's Landw. Ztg., 56 (1907), No. 12, pp. 409–438; abs. in Chem. Zentbl., 1907, I, No. 24, p. 1702*).—The author summarizes and discusses the results of his numerous experiments on the importance of manure as a means of increasing the bacteria content of soils, in increasing the activity of the soil bacteria, and on the influence of this bacterial activity on the plant food and properties of soils.

He concludes that the most beneficial effect on the bacterial activity of the soil is brought about in practice by frequent small applications of manure rather than by large applications at longer intervals, the action of the manure being assisted by thorough aeration of the soil by cultivation, drainage, etc.

On the action of barnyard manure, J. STOKLASA (*Illus. Landw. Ztg.*, *27* (*1907*), *No. 47, pp. 425–427; 48, pp. 433–436*).—This is an abstract of a paper presented at the International Congress of Agriculture in Vienna, and presents in a popular way the well-known views of the author regarding the relation of manuring to bacterial activity in the soil. (See p. 421.)

The world's production and consumption of mineral fertilizers, L. GRANDEAU (*L'Agriculture et les Institutions Agricoles du Monde au Commencement du XX^e Siècle. Paris, 1906, Vol. 4, pp. 277–327, figs. 2*).—This comprises chapters 55 to 59 of the fourth volume of the author's report on agriculture and agricultural institutions of the world at the beginning of the twentieth century, based upon the Paris Exposition of 1900. The subjects discussed are the origin of mineral fertilizers and the increased yield due to their use, the production and use of various kinds of phosphatic, potassic, and nitrogenous fertilizers being considered in detail.

History of the fertilizer industry, W. D. RHEA (*Tradesman, 57* (*1907*), *No. 10, pp. 57, 58*).—This is a brief note on the origin and present status of the industry in general, but dealing more particularly with the fertilizer business of Nashville, Tenn.

The total fertilizer production of the United States is placed at 4,000,000 tons annually, valued at over $60,000,000. It is estimated that Nashville has $3,000,000 invested in the fertilizer business.

Phosphate production in 1906 (*U. S. Geol. Survey, Press Bul. 295, folio*).—This is an advance notice of the chapter of Mineral Resources of the United States for 1906, on phosphate production in the United States.

It is stated that "of the 2,080,957 long tons of phosphate marketed in the United States in 1906 (valued at $8,579,437), Florida produced 1,304,505 long tons, valued at $5,585,578; the Tennessee production was 547,677 long tons, valued at $2,147,991; and South Carolina's production amounted to 223,675 long tons, valued at $817,068. Other States, including Arkansas and Idaho, produced 5,100 tons, valued at $28,800."

The demand for phosphate in recent years has grown more rapidly than the output, resulting in a rise of prices. It is suggested that under these conditions of growing demand and higher prices it is not improbable that many low-grade deposits which it has hitherto been impracticable to utilize may be profitably worked. Reference is made to recently discovered deposits in Tennessee, Utah, Wyoming, Idaho, and Arkansas.

The third German potash congress, WEISKOPF (*Ztschr. Angew. Chem.*, *20* (*1907*), *No. 25, pp. 1025–1062, figs. 2*).—This is an account of the proceedings of a meeting of chemists and others interested in the potash industry at Hildesheim May 4–5, 1907. The more important subjects considered were a report on the basis for a scientific development of the North German potash deposits, including investigations on the solubility of salt mixtures and on the formation and transformation of salts, and physical and mineralogical investigations; the drainage water question in the potash industry; and the industrial analysis of potash salts.

Problems of applied chemistry, G. LUNGE (*Chem. News, 95* (*1907*), *Nos. 2470, pp. 151–153; 2471, pp. 159–162; 2472, pp. 172–175*).—Among the most important problems of applied chemistry referred to in this article is the artificial production of fertilizers, more particularly the production of nitrogenous compounds from the free nitrogen of the air. The relative cost and efficiency and the future possibilities of the Frank and Caro and Birkeland and Eyde processes of preparing nitrogenous compounds are discussed. Attention is also called to the progress which has been made by Frank, Caro, and Mond in utilizing peat for the production of power and of ammonia, as well as the application of the Mond and other processes for the recovery of ammonia from the gases of coke ovens, furnaces, etc.

The synthetical production of foods and feeding stuffs and the application of chemistry in the preparation of foods from new sources and increasing the production from old sources are briefly referred to.

The fixation of nitrogen, N. WHITEHOUSE (*Jour. Soc. Chem. Indus., 26 (1907), No. 13, pp. 738, 739*).—A study of various methods with a view to working out a practical commercial process for the fixation of atmospheric nitrogen as ammonia or nitrate, using a metallic nitride as the nitrogen carrier, is briefly reported. The results are mainly of theoretical interest.

On the oxidation of nitrogen by the action of silent discharges on atmospheric air, E. WARBURG and G. LEITHÄUSER (*Sitzber. K. Preuss. Akad. Wiss., 1907, No. 11–13, pp. 229–234, figs. 2*).—The investigations here reported show that the product of the oxidation of dry atmospheric air by silent discharges is mainly N_2O_5.

On the formation of calcium cyanamid and calcium carbid, E. RUDOLFI (*Ztschr. Anorgan. Chem., 54 (1907), No. 2, pp. 170–184, fig. 1; abs. in Chem. Ztg. 31 (1907), No. 58, Repert. No. 53, p. 351*).—Studies of the formation of calcium cyanamid by the action of nitrogen on crude carbid with and without addition of other substances (calcium chlorid, fluorid, iodid) and from the components lime, charcoal, and nitrogen, are reported. Incidentally the equilibrium temperatures of Rothmund for the formation of calcium carbid out of lime and charcoal were investigated and found too low.

The formation of lime nitrogen, F. FOERSTER and H. JACOBY (*Ztschr. Elektrochem., 13 (1907), No. 12, pp. 101–107; abs. in Jour. Soc. Chem. Indus., 26 (1907), No. 8, p. 423*).—Studies of the influence of temperature and of adding calcium chlorid and fluorid are reported.

Contributions to the study of calcium phosphates, H. BASSETT, Jr. (*Ztschr. Anorgan. Chem., 53 (1907), No. 1, pp. 34–62*).—Studies of the hydrates of the calcium hydro-orthophosphates and of the action of ammonia gas on the calcium hydro-orthophosphates are reported.

Phosphates and superphosphates in relation to the sulphur industry, L. TIRELLI (*Rass. Min., 26 (1907), Nos. 7, pp. 101–103; 8, pp. 118–120; abs. in Chem. Abs., 1 (1907), No. 12, p. 1601*).—Laboratory experiments are reported which indicate that it is not practicable to use the sulphur dioxid, formed in the process of extracting sulphur from minerals by partial combustion, in the manufacture of superphosphates.

Fertilizers, A. STUTZER (*Düngerlehre. Leipsic, 1907, 16. rev. ed.; rev. in Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 6, p. 578*).—This is the sixteenth revised edition of this work.

The use of chemical fertilizers, MINANGOIN (*Bul. Soc. Hort. Tunisie, 6 (1907), Nos. 24, pp. 20–26; 25, pp. 81–87*).—This subject is discussed mainly from the standpoint of Tunisian conditions.

Results of field experiments with fertilizers in Belgium, SCHREIBER (*Bul. Agr. [Brussels], 23 (1907), No. 7, pp. 445–485*).—The results of 3 years' experiments with various crops on the typical soils of the different regions of the country are briefly summarized.

Culture experiments and critical studies on the relative efficiency of nitrate of soda and sulphate of ammonia, H. STÜCHTING (*Jour. Landw., 55*

(1907), No. 1, pp. 1–46; abs. in Chem. Abs., 1 (1907), No. 13, p. 1754; Jour. Chem. Soc. [London], 92 (1907), No. 538, II, p. 646).—The author reviews previous investigations upon this subject, discusses the factors affecting the action of the two materials, and reports pot experiments with potatoes, from which he draws the following conclusions: The absolute consumption of water by potatoes was greater in case of ammonium sulphate than in case of nitrate of soda. The absolute water consumption was higher, and the relative consumption considerably lower with potash fertilizers than without them; that is, the water was better utilized with potash fertilizers. Ammonium sulphate gave better yields than nitrate of soda. Only the highest yield of potatoes with nitrate nitrogen equalled the effect of ammonia nitrogen.

The assimilation of nitrogen by potatoes was the same in case of nitrate nitrogen (calcium nitrate) and ammonium sulphate. Probably the sulphuric acid set free by the assimilation processes influenced the utilization of nitrogen unfavorably and the taking up of potash favorably. The sodium residue left in the soil, when present in small amounts, increased the nitrogen assimilation, but when present in larger amounts, reduced nitrogen assimilation. In like manner the soda reduced the assimilation of potash by plants. This action is attributed in part to the alkaline nature of the sodium residue. Unlike other cultivated plants (beets, barley, and carrots) the potato was not favorably influenced by soda directly. The two varieties of potatoes experimented with, July and Silesia, behaved very differently toward this incidental action of the nitrate of soda and sulphate of ammonia.

Experiments with ammonium sulphate, Bachmann (*Fühling's Landw. Ztg., 56 (1907), No. 15, pp. 530–535*).—In continuation of previous experiments (E. S. R., 18, p. 725), the author studied the effect of time of application of ammonium sulphate and the comparative effect of the sulphate and other nitrogenous fertilizers on rye, oats, barley, kohl-rabi, and mangolds on different kinds of soil.

As a rule early application in the spring gave better results than later, and one application than fractional applications. The sulphate gave better results than nitrate of soda or the organic nitrogen of manure.

Field experiments with nitrogen-lime for sugar beets, F. Strohmer (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 35 (1906), pp. 663–675; abs. in Chem. Zentbl., 1907, I, No. 19, p. 1451; Jour. Chem. Soc. [London], 92 (1907), No. 538, II, pp. 646, 647*).—The nitrogen of nitrogen-lime, prepared by the Polzenius process, is in the same form as in lime nitrogen. In the experiments reported, nitrogen-lime gave good results on sugar beets, but the best methods of applying it remain to be worked out and the economy of its use depends upon its cost, which has not yet been fixed commercially.

Previous experiments of this kind have been noted (E. S. R., 18, p. 19).

Comparative fertilizer experiments with lime nitrogen, M. Schmoeger (*Mitt. Deut. Landw. Gesell, 22 (1907), No. 10, pp. 103–105*).—Five years' comparative tests of lime nitrogen, ammonium sulphate, and nitrate of soda on oats and potatoes are reported, showing uniformly best results with nitrate of soda, and slightly poorer and less uniform results with ammonium sulphate. Lime nitrogen was slightly less effective than ammonium sulphate but very similar to it in action.

Experiments with lime nitrogen and nitrogen lime, H. Immendorff (*Mitt. Deut. Landw. Gesell., 22 (1907), No. 9, pp. 93–95; Sächs. Landw. Ztschr., 55 (1907), No. 14, pp. 317–319*).—Experiments with wheat, barley, and oats, show that these fertilizers gave good results as compared with nitrate of soda, and indicate that they may be used with advantage by farmers under suitable conditions.

The question of sulphate of iron, C. Guffroy (*Jour. Agr. Prat., n. ser., 13 (1907), No. 25, pp. 782–786*).—Various experiments with this material as a fertilizer on soils of different character are reviewed.

In experiments with 4 Gramineæ which are reported the sulphate of iron was decidedly beneficial on oats, less beneficial in case of rye, without action on rye grass, and harmful to wheat. The very variable results which have been obtained with sulphate of iron lead to the conclusion that its action is not purely chemical, but that it may influence the biological processes in the soil.

Investigations on the composition and fertilizing value of Posen sewage, Gerlach (*Mitt. Deut. Landw. Gesell., 22 (1907), Nos. 18, pp. 169–174; 19, pp. 177–180*).—The Posen sewage is collected in tanks and is therefore more concentrated than ordinary city sewage, 1 cubic meter of it containing on an average 5 kg. of total nitrogen, 3 kg. of soluble nitrogen, 1.25 kg. of phosphoric acid, and 2.25 kg. of potash. Experiments with rye and potatoes showed that in all cases the sewage was an effective fertilizer, its efficiency, however, depending largely upon the previous crop and the weather.

Experiments on the fertilizing action of olive pomace ashes, D. Vigiani (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 4 (1907), No. 1, pp. 66–70*).—Analyses of this material are reported showing from 11.19 to 25.02 per cent of potash, 10.88 to 19.56 per cent of lime, and 1.74 to 3.85 per cent of phosphoric acid. From the chemical analyses and from experiments with olives, grapes, sweet potatoes, and rape the author concludes that the ashes constitute an excellent fertilizer, rich in potash and phosphoric acid, which can be economically used wherever a supply is available.

The action of the lime waste of sugar factories as a fertilizer, Rupprecht (*Deut. Landw. Presse, 34 (1907), No. 62, p. 503*).—It is stated that this material contains on an average 1.2 per cent of phosphoric acid, 0.2 per cent of potash, and 23 per cent of lime. It is mainly valuable for the lime it contains and gives good results on soils in need of this substance and on plants specially benefited by liming, such as most leguminous plants. The phosphoric acid, though small in amount, is quite effective. The waste is considered most effective when used in connection with manure.

Fertilizer analyses, A. J. Patten (*Michigan Sta. Bul. 248, pp. 16*).—The results of inspection of 145 brands of fertilizers examined during the season of 1907 are reported.

Licensed commercial fertilizers, 1907, F. W. Woll and G. A. Olson (*Wisconsin Sta. Bul. 149, pp. 3–19, 26–28*).—Analyses of 40 samples, representing 22 brands, of fertilizers licensed for sale in Wisconsin in 1907 are reported, with the text of the State fertilizer law; a discussion of the composition and valuation of fertilizers; and suggestions as to the purchase and use of fertilizers.

AGRICULTURAL BOTANY.

The assimilation of atmospheric nitrogen by fungi, Charlotte Ternetz (*Jahrb. Wiss. Bot. [Pringsheim], 44 (1907), No. 3, pp. 353–408, figs. 2*).—While making a study of the turf-inhabiting fungi, the author isolated 8 species living as mycorrhiza on the roots of various common ericads, a preliminary account of which has already been noted (E. S. R., 16, p. 541).

In the present paper technical descriptions are given of 5 new species, *Phoma radicis oxycocci, P. radicis andromedæ, P. radicis vaccinii, P. radicis tetralicis,* and *P. radicis ericæ,* together with a detailed account of their nitrogen assimilating power. All of the species seem to be able to assimilate atmospheric nitrogen in various degrees, the most active being *P. radicis vaccinii, P. radicis oxycocci,* and *P. radicis andromedæ.* These 3 species are doubtless of great economic importance, as for each gram of dextrose consumed they fix 22, 18, and 11 mg. of nitrogen, respectively. *Aspergillus niger* and *Penicillium glaucum* were also found to be able to fix free nitrogen, but in a much less degree. None of the fungi investigated were found to require combined nitrogen for their development.

The rôle of lime in plants, V. GRAFE and L. VON PORTHEIM (*Sitzber. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 115 (1906), No. 6, pp. 1003–1037, pls. 2*).—Two series of experiments were made with bean seedlings in Knop's solution to determine the rôle of lime in the assimilation and metabolism of sugars, starch, etc. The seedlings were placed in cultures with and without lime, and 1 per cent each of levulose, saccharose, and dextrose added to different jars. The cultures were kept under observation in light and darkness and their growth and general behavior noted, comparisons being made with seedlings grown in the normal solution.

The development of hypocotyl and roots was best in the series grown in normal solution to which 1 per cent levulose was added. Where lime was omitted the growth was less in every series, and the roots were distorted, brown, and insignificant.

A second series of experiments was conducted at a somewhat lower temperature, but the results were quite similar to those obtained before.

The authors found formaldehyde present in the green plants whether grown with or without lime, but further experiments are said to be necessary to determine whether the injurious action of formaldehyde is inhibited by the presence of lime.

Plants containing hydrocyanic acid, P. GUÉRIN (*Rev. Sci. [Paris], 5. ser., 8 (1907), Nos. 3, pp. 65–74; 4, pp. 106–110*).—The author presents a review of some of the more important contributions to our knowledge regarding the occurrence and function of hydrocyanic acid in plants.

The latent life of seeds, P. BECQUEREL (*Ann. Sci. Nat. Bot., 9. ser., 5 (1907), No. 4–5, pp. 193–311*).—The results of a prolonged study of a large number of species of seeds are given, a preliminary account of some of the experiments having already been noted (E. S. R., 18, p. 330).

The author found that the integument of some seeds after a certain amount of drying became impermeable, so that the seeds exhibited no swelling even after a lapse of two years. Under the prolonged action of water or water vapor the integument of most seeds becomes permeable, allowing gases to comply with the usual laws of diffusion. Alcohol, ether, chloroform, and acids had no effect on the vitality of seeds so long as the seed coats remained impermeable. When subjected to the extremely low temperatures of liquid air the influence of this medium was proportional to the amount of water in the seeds. Tests of old seeds showed that they did not retain their vitality indefinitely.

The gaseous exchange in seeds kept in the dark for a month or two was reduced to a minimum. On the contrary, it was considerably increased in seeds kept in the light. The permeability of the seed coats and the proportion of dehydration of the seed was also found to influence it. The exchange of gases in latent seeds is said to be due to simple chemical oxidation, and it can be entirely suspended for a time without destroying the germinative power of the seed. The dehydration of the seed was found essential to prolonged vitality.

The author was unable to determine whether anaerobic life in seeds is due to an actual suspension of the power of assimilation on the part of the protoplasm or whether the protoplasm and nucleus of the cell are nourished by the reserve material and the phenomena of life carried on, but in a very greatly reduced degree.

A bibliography of more than 100 references to the literature of the subject is appended.

The variations in the intensity of respiration and of dry substance of flowers during their development, A. Maige (*Bul. Soc. Bot. France, 53 (1906), pp. XLVI-XLVIII*).—The results of experiments with 21 species of plants that bloomed in September at Fontainebleau and in December at Algiers are given. In every case four lots of flowers in different stages of development were weighed and then placed in flasks containing definite amounts of air. From time to time the air was sampled and the amount of carbon dioxid determined. Knowing the dry weight per gram of fresh material and the respiratory quotient of the fresh flowers, the proportion between the respiration and dry weight was readily calculated.

It was found that for the flowers of most plants the ratio between fresh weight and carbon dioxid liberated decreased regularly as the flowers grew and expanded. For a few plants the intensity of respiration was greatest in the expanded flowers. The same conclusions were arrived at where the dry weight was considered. The respiration of the individual flower almost always increased from the youngest stages to the open flower. For the most part the dry weight per gram of fresh material in the flower decreased with the increased development, the rate varying with the different species.

Heredity and Mendel's law, C. B. Davenport (*Proc. Wash. Acad. Sci., 9 (1907), pp. 179-187*).—This is an address delivered by the author under the auspices of the Washington Academy of Sciences in which he discusses those changes in the germ-plasm due to combinations of two dissimilar sorts and the effect of such combinations on the stream of germ-plasm that issues from the union, the illustrations being drawn from the author's experiments with fowls.

Mendelism and other methods of descent, O. F. Cook (*Proc. Wash. Acad. Sci., 9 (1907), pp. 189-240*).—This is a discussion of Mendelism and other methods of descent, the paper being an amplification of an outline presented by the author before the Washington Academy of Sciences on February 26, 1907.

International catalogue of scientific literature. R—Bacteriology (*Internat. Cat. Sci. Lit., 5 (1907), pp. VIII+837*).—The present volume is in continuation of the series previously described (E. S. R., 14, p. 1049) and is intended to cover the bacteriological literature of 1905 with such articles appearing in 1901-1904 as were omitted in previous issues. The arrangement is by authors and subjects, over 6,000 titles being given.

There are a number of titles of papers that would hardly be looked for in this publication, and the inclusion of lists of Agaricaceæ, Ustilaginaceæ, and titles relating to diseases of plants that are due to some of the higher fungi can hardly be justified. The American bacteriological literature is almost wholly neglected. Only about 50 titles are given of papers published in this country, and most of those are from 2 or 3 sources only. The work of this Department and of the State experiment stations appears to have been neglected entirely.

FIELD CROPS.

The breeding of agricultural plants, C. Fruwirth (*Die Züchtung der Landwirtschaftlichen Kulturpflanzen. Berlin, 1907, pp. XV+380, figs. 30*).—Previous volumes of this work have already been noted (E. S. R., 17, p. 1055). This volume, the fourth of the series, treats of the breeding of wheat, rye, barley, oats, and sugar beets. In its preparation E. von Proskowetz, E. von Tschermak, and H. Briem were associated with the author and the work was so divided that the subject of blossoming and pollination in cereals and the sugar beet are discussed by Fruwirth, correlations in the cereals by von Tschermak, correlations in the sugar beet by von Proskowetz, the technic of breeding cereals with the exclusion of hybridization by Fruwirth, the technic in breeding sugar beets by Briem and von Proskowetz, and the hybridization of the cereals and the sugar beet by von Tschermak. The volume contains a number of bibliographies relating to the different subjects treated.

Campbell's soil culture manual, H. W. Campbell (*Lincoln, Nebr., 1907, pp. 320, pl. 1, figs. 52*).—This book, a farmers' guide adapted to semiarid regions, describes the different implements used in dry farming, discusses the value and methods of soil treatment to conserve soil moisture, and gives directions for growing the ordinary farm crops under semiarid conditions without irrigation. Special attention is given to corn, wheat, potatoes, sugar beets, alfalfa, and tree culture.

Proceedings of the trans-Missouri dry farming congress (*Proc. Trans-Missouri Dry Farming Cong., 1907, pp. 248*).—A collection of the different papers presented at this congress held at Denver, January 24–26, 1907, together with the discussions on different phases of farming in the semiarid regions without irrigation.

Report of work at McNeill branch experiment station for 1906, E. B. Ferris (*Mississippi Sta. Bul. 101, pp. 1–4; 11–20, figs. 2*).—General statements with reference to the year's work at the station are given. As in previous years fertilizer tests were made with a number of crops.

In experiments with cotton, in which as a rule cotton-seed meal, acid phosphate, and kainit were applied at the rate of 100 lbs. each per acre in different combinations, the best yield, 1,060 lbs. of seed cotton per acre, was secured from the use of acid phosphate and cotton-seed meal. In another test conducted to determine whether the addition of kainit to cotton-seed meal and acid phosphate would increase the yield, the use of acid phosphate and cotton-seed meal gave 1,540 lbs., while the application containing 100 lbs. of kainit in addition gave only 1,485 lbs. of seed cotton per acre. The effects of manure left by cattle in the winter of 1902–3 was still quite perceptible this year. The yields of different varieties of cotton compared ranged from 975 lbs. to 1,385 lbs. of seed cotton per acre. The leading sorts and their yields were as follows: Cook Improved 1,385 lbs., Culpepper 1,300 lbs., Cleveland Big Boll 1,265 lbs., Hunnicutt Big Boll 1,260 lbs., Toole Improved 1,245 lbs., Rogers 1,220 lbs., and Florodora 1,210 lbs.

The average yields of corn per acre in the fertilizer tests ranged from 14.6 bu. on the plat receiving no fertilizer, to 28.6 bu. on the plat receiving 100 lbs. each of cotton-seed meal, acid phosphate, and kainit. The lowest yield on any fertilized plat, 18.6 bu., was secured where 100 lbs. of kainit was applied alone. The plat given 100 lbs. acid phosphate alone ranked second in yield with 28.3 bu. On parked land receiving 100 lbs. each of acid phosphate and cotton-seed meal 36.5 bu. was secured, and only 33.3 bu. when in addition 100 lbs. of kainit was given. The leading varieties of corn and their yields per acre were as follows: Cocke Prolific 35.3 bu., Eureka 35.1 bu., Mosby Prolific 32.8 bu., and Early Breadfield 32 bu.

Oats and vetch, sown in the proportion of 4 to 1 on land fertilized with a light application of stable manure and 400 lbs. per acre of a mixture of equal parts of acid phosphate and cotton-seed meal, were cut on April 30 and produced 6,090 lbs. of well cured hay per acre. The land then produced a crop of 30 bu. of Mosby Prolific corn and a fair crop of cowpeas for turning under in the fall. Brief cultural notes on different forage crops are given.

The best average yield of plant cane, 30,050 lbs. per acre, was secured where 400 lbs. of cotton-seed meal and 200 lbs. of acid phosphate had been applied. The check plat produced 31,245 lbs. In experiments with stubble cane a mixture containing 210 lbs. each of cotton-seed meal and acid phosphate and 90 lbs. of kainit was taken as a unit application and gave a yield per acre of 33,856 lbs. of cane. Where the acid phosphate was doubled 41,536 lbs. was obtained, and where the unit application was doubled, one-half being applied on May 16 and the other half on July 10, 41,984 lbs. of cane was secured. Applying double the unit application on May 16 gave 40,896 lbs., and when cotton-seed meal and acid phosphate were normal and the kainit omitted the yield was 33,920 lbs. Half the unit application gave 33,856 lbs., and four times the unit application 45,312 lbs., while the land receiving no fertilizer produced 31,744 lbs. Land on which the nitrogen application was doubled and the phosphorus and potassium left normal gave 36,032 lbs.

Land receiving no fertilizer yielded 13,550 lbs. of sweet potatoes per acre, and the best yield on fertilized land, 15,910 lbs., was secured where 150 lbs. each of cotton-seed meal, acid phosphate, and kainit had been given.

Three tests were made to show the effect of fertilizers on cowpeas, and the best yield, consisting of 1,330 lbs. of peas in the hull and 820 lbs. of hay per acre, was secured where a mixture of 200 lbs. each of acid phosphate and kainit was applied. The use of fertilizers apparently affected the yield of peas more than the yield of hay. Some of the leading hay-producing varieties and their yields per acre were as follows: Wonderful 4,200 lbs., Red Ripper 3,504 lbs., Iron 3,329 lbs., and Clay 3,043 lbs.

The results of an experiment in which the rotation of crops and the use of fertilizers were combined showed an increase of 17 per cent in the productive capacity of the soil after 3 years, while land growing cotton continuously showed a reduction in its productive capacity of 16 per cent. It was further found that the use of fertilizers is necessary on this soil for the satisfactory growth of cowpeas in the rotation.

Annual report of the Hawaii Agricultural Experiment Station for 1906 [Field crops], J. G. SMITH (*Hawaii Sta. Rpt. 1906, pp. 10-15*).—Potatoes grown at the station were severely attacked by a form of rot which very much reduced the yield. The crop secured was disposed of as new potatoes at 5 cts. per pound.

The yield of upland varieties of cotton tested at the station was not specially promising, but Peruvian and Sea Island cotton were for the most part good in quality and gave a large yield. The quality of the Peruvian, however, varied widely, and this is considered as indicating an excellent opportunity for improvement by selection.

Experiments have been inaugurated with tobacco at Hamakua. The tobaccos under test are Sumatra, Turkish, Cuban, and various seed-leaf strains from Connecticut, Pennsylvania, and other tobacco-producing States. The experiment was not quite complete when the report was made, but the results are regarded as indicating that tobacco of good burn, texture, flavor, and color can be produced on a commercial scale in certain districts in Hawaii.

Through the cooperation of the Bureau of Plant Industry of this Department 150 varieties of rice were obtained from different parts of the world for comparison with local varieties. This work has been undertaken with a view to assist in the restoration of rice growing to its former important position in the islands.

[Report on field crops], G. H. TRUE (*Nevada Sta. Rpt. 1906, pp. 27-29*).—Plowing up, leveling, and reseeding old alfalfa ground at the station has given good results. Three acres reseeded in 1904, which in previous years had not yielded over 1.5 tons per acre, gave a total yield in 1905 of 7.9 tons.

The results of the flooding method of irrigating wheat and oats proved more economical than those of the furrow method. White Australian wheat was grown in this test. One-half acre of this variety planted in the fall and irrigated but once in the spring yielded at the rate of 2,376 lbs. of grain per acre. A yield of 2,763 lbs. of grain was produced per acre foot of water.

In a culture test with root crops 1 acre of the long red mangel produced 15.8 tons.

Results of cooperative experiments in agriculture, J. Buchanan (*Ann. Rpt. Ontario Agr. and Expt. Union, 28 (1906), pp. 13–27*).—Earlier results of this work have been previously reported (E. S. R., 18, p. 27).

In the cooperative experiments of 1906 the leading varieties of grain crops gave the following average yields per acre: Siberian oats, 104 tests, 51.18 bu.; Mandscheuri Six-rowed barley, 57 tests, 37.95 bu.; Two-rowed Canadian barley, 3 tests, 23.88 bu.; Guy Mayle Hulless barley, 14 tests, 22.19 bu.; Wild Goose spring wheat, 23 tests, 24.19 bu.; Common emmer, 11 tests, 39.46 bu.; Red spelt as compared with emmer, 27.64 bu.; Japanese buckwheat, 3 tests, 27.78 bu.; Early Britain field peas, 55 tests, 23.79 bu.; White Wonder field beans, 17 tests, 20.05 bu.; Early Yellow soy beans, 1 test, 16.33 bu.; Banatka winter wheat, 17 tests, 30.01 bu.; Compton Early corn, 16 tests, 60.16 bu. The best and most popular mixture of grains consisted of 34 lbs. of Daubeney oats and 48 lbs. of Mandscheuri barley per acre, which produced on the average in 12 tests 1,505 lbs. of grain per acre. In all cases except two the varieties here mentioned ranked first in popularity, Mandscheuri barley and Early Britain field peas being the exception.

The leading varieties of field roots and fodder crops gave the following yields per acre: Yellow Leviathan mangels, 7 tests, 42.66 tons; Giant White Feeding sugar beets, 7 tests, 39.13 tons; Sutton Magnum Bonum swedes, 6 tests, 20.83 tons; Mastodon White Intermediate carrots, 5 tests, 18.26 tons; Buckbee New Sugar parsnips as compared with carrots, 14.79 tons; Henderson Eureka fodder corn, 4 tests, 16.75 tons; Japanese Barnyard millet, 5 tests, 12.03 tons; Kafir corn, 1 test, 9.80 tons; Early Minnesota sugar cane as compared with Kafir corn, 9.24 tons; Dwarf Bonanza rape, 1 test, 25.48 tons. In 3 tests hairy vetches, grass peas, and common vetches gave 7.87, 7.31, and 6.75 tons per acre, respectively. Nearly all these varieties were the most popular with the experimenters, excepting Mastodon White Intermediate carrot and Henderson Eureka fodder corn, which were outranked by Bruce Mammoth Intermediate carrot and White Cap Yellow Dent fodder corn, respectively. Grass peas and common vetches were preferred to hairy vetches. Mangel seed sown on the level produced a yield of 33.3 tons of roots per acre as compared with 30.7 tons where the seed was sown in drills.

Ringleader, Golden Bantam, and Mammoth White Cory sweet corn, requiring 70, 73, and 74 days, respectively, to mature for table use, were grown in 20 tests. In comparative value, Ringleader and Mammoth White Cory outranked Golden Bantam, which stood first in table quality.

In the fertilizer experiments conducted in the previous years the greatest average yield of oats for 5 years in 74 tests was secured by the use of the complete fertilizer, while the greatest average yield of mangels for 5 years in 41 tests was obtained where nitrate of soda was applied. The total yield of fodder corn for 8 years in 47 tests was the same from the use of nitrate of soda, the complete fertilizer, and of muriate of potash, but the yield of husked ears was slightly in favor of the complete fertilizer. The highest average yield of swedes for 4 years in 12 tests, 30.1 tons per acre, was secured where 40,000 lbs. of cow manure was applied per acre.

The average yields of 3 late varieties of potatoes, Empire State, Dempsy Seedling, and American Wonder, grown in 86 tests, were, respectively, 174.67, 168.49, and 165.80 bu. per acre. Of 3 medium varieties, grown in 70 tests, Rose of the North ranked first, Burpee Extra Early second, and Seedling No. 230 last. Rose of the North, which produced 164.36 bu. per acre, also ranked first in comparative value. The leading early variety was Early Dawn, which ranked first in yield and comparative value in 144 trials.

[Notes on alfalfa and sugar beets], P. K. BLINN (*Colorado Sta. Bul. 121, pp. 1–6, figs. 4*).—Brief comments on the alfalfa seed nursery established in 1905, and on the work of developing a disease-resistant sugar beet are presented. The characteristics of a number of individual alfalfa plants are noted, and some of the points observed in the sugar-beet work are summarized. These notes are intended as a report of progress.

The work of selecting mother beets for growing seed has pointed out the wide variation of the seed-producing tendency of individuals and has demonstrated that the seed yield can be materially influenced. It was found that a large number of beets would not grow a seed stock and that uniform seed production depends largely upon the proper soil conditions and the manner of setting out the beets. Well-matured beets of good shape and size are selected, the leaves removed without injury to the center or crown buds, layered in dry soil in deep, narrow ventilated pits protected from frost, and set out early in April for seed production.

Alfalfa, P. G. HOLDEN (*Iowa Sta. Circ. 1, pp. 4*).—Popular directions for alfalfa culture are given and the advantages and disadvantages of the crop are pointed out. The points emphasized are "the manuring of the ground before plowing, removing the small grain and preparing just as soon as possible after the small grain has been harvested, thorough preparation of the ground, and sowing not later than August 10 to 20, and beginning on a small scale."

The nitrogen content of barley in its relation to the structure of the meal in the kernel, E. JALOWETZ (*Abs. in Zentbl. Agr. Chem., 36 (1907), No. 4, pp. 229–232*).—The formalin method of treatment was used in testing the relative mealiness and hardness of the kernels.

Barley grains were soaked for 30 minutes in commercial formalin at the boiling point of water. After this treatment they were washed 4 or 5 times with cold well water and dried between filter papers for the purpose of removing the formalin solution. As grains from the upper half of the head are known to be richer in nitrogen than those from the lower half, samples were prepared to determine the effect of this treatment on the grains from the two parts. The dissolution of the lower kernels was effected more readily than that of the grains taken from the upper part. The action of the formalin was best observed in grains containing from 1.6 to 1.8 per cent of nitrogen.

On account of their higher nitrogen content the grains from the upper part of the head differ in structure from those produced in the lower portion of the spike, this difference being manifested by hardness and glassiness. Attention is called to the fact that with all grains mealy, or nearly so, the barley is low in nitrogen, while if the kernels are glassy and hard the barley is high in nitrogen content. If a sample after formalin treatment shows both mealy and glassy grains it is evidence that the barley is composed of some kernels low and others high in nitrogen. An analysis showed that the mealy kernels contained 1.16 per cent nitrogen, half glassy kernels 1.59 per cent, and glassy kernels 1.70 per cent.

On the physiological effects of an excess of magnesia upon barley, S. KUMAKIRA (*Bul. Col. Agr. Tokyo Imp. Univ., 7 (1907), No. 3, pp. 441, 442*).—Six pots holding 8 kg. of loamy humus soil, containing 0.5 per cent CaO and 0.4 per cent MgO soluble in 10 per cent solution of hydrochloric acid, were fertilized with double superphosphate, sodium nitrate, ammonium sulphate, and potassium sulphate. Twenty-five grains of barley were sown in each pot

Nov. 28, and the young plants a month later reduced to 15 of equal size per pot. Two check pots received no further addition, 2 received 10 gm. of crystallized magnesium sulphate in high dilution, and 2 received each 50 gm. of the same salt.

It was found that an excess of magnesia over lime retarded growth and maturity in proportion to the amount of magnesia in excess. A moderate excess of this substance did not diminish the number of shoots, but a large excess reduced the number of stalks developed by the plant. It was also shown that large quantities of magnesia in the soil diminished the strength of the leaf sheath and of the stalks.

Indian corn, A. M. TEN EYCK and V. M. SHOESMITH (*Kansas Sta. Bul. 147, pp. 225–295, figs. 26*).—The experiments reported have as a rule been in progress from 1903 to 1906, inclusive. Of 112 varieties tested during this time, Hildreth, Kansas Sunflower, McAuley, Forsythe Favorite, Golden Row, Hammett, Leaming, U. S. P. B. Selection No. 77, Hogue Yellow Dent, Sanders Improved, White Salamander, Red Cob White Dent, White Injun, Legal Tender, Warner, Mammoth Golden Yellow, Dyche, Meinhardt, and Hiawatha Yellow Dent were superior in productiveness. From 121 to 143 days, with an average of 129 days, were required to mature corn in 1905. Of the better yielding varieties grown for the 4 years, 16 maturing in 126 days or less produced on an average 61.45 bu. per acre, while 19 ripening in 127 days or more yielded 64.94 bu. per acre.

For the 4 years listing early in the spring and splitting the ridges at planting time gave an average increase of 5.02 bu. per acre over giving no early cultivation. Early listing produced better results and also conserved more water in the soil than early disking. Surface-planted corn yielded on an average 6.65 bu. more corn and 469 lbs. more stover per acre than listed corn. The wet seasons favored surface planting and the dry seasons listing. A test of different methods of planting in 1905 resulted in a yield per acre of 53.24 bu. for surface planting with the disk furrow-opener attachment, 51.94 bu. for ordinary surface planting, and 48.33 bu. for listing.

Soil moisture studies in this connection showed without exception that as compared with surface planting listing favored the conservation of soil moisture in the latter part of the season. This is considered as due possibly to the roots lying relatively deeper in the soil and allowing for somewhat deeper cultivation, but also to the fact that the listed corn was laid by with level cultivation while the surface-planted corn was slightly hilled. During 2 seasons the largest average yields were secured by planting May 26, and the results in general apparently favor rather late planting as compared with early planting. The difference in results from various methods of cultivating corn was not sufficient for very definite conclusions. It appeared that the exact method of cultivation, whether deep or shallow, was not of so great importance as the conditions of soil or season as related to the proper time of cultivation. The soil moisture determinations showed no marked variation on the several plats.

In the comparative fertilizer tests in 1906 the largest yield, 56.63 bu. per acre, was secured on land treated with barnyard manure at the rate of 13 tons per acre. The next largest yield, 40 bu. per acre, was obtained on the plat treated with 50 lbs. of nitrate of soda applied broadcast. The average production of the unfertilized land was 33.21 bu. per acre.

The results of rotation tests for 4 years were as follows: Corn after potatoes, 69.98 bu. per acre, after soy beans, 67.55 bu., and after corn, 60.74 bu., while after wheat, barley, oats, and emmer the yields were smaller than where corn was grown after corn, but the lowest yields were produced after Kafir and sorghum. In value of total products in 4 years the rotation of corn with potatoes ranked first with $43.47 per acre; corn after Kafir corn, second, with $34.46 per acre; corn after sorghum, third, with $31.15, and corn continuously, fourth, with $31.07.

A summary of the results of shrinkage experiments carried on for 3 seasons shows a loss in weight of 3.26 per cent for the first 4 months after the corn was placed in the crib, 5.16 per cent for the first 6 months, 6.80 per cent for the first 8 months, 7.44 per cent for the first 10 months, and 8.62 per cent for the first year. The average shrinkage of yellow corn was 11.21 per cent in 12 months, of white corn 8.48 per cent, and of mixed corn or samples of many varieties only 6.18 per cent. It is considered that the average result of the shrinkage trials indicates that corn cribbed fairly dry and in good condition should not shrink over 5 per cent during the winter months. Attention is called to the fact, however, that in these experiments great care was exercised to prevent loss from other causes.

The corn-breeding work of the station is described. It was found that in some tests there was a difference of more than 400 per cent in the yields from different ear rows. In 1906, the Silvermine high-yielding-rows seed plat yielded 32 per cent more corn and 24.8 per cent more first-grade seed ears than the plat planted with first-grade seed. The Hildreth high-yielding-rows seed plat yielded 10.36 per cent more corn and 40 per cent more first-grade seed ears than the plat planted with first-grade seed of this variety. It is pointed out that the results of the breeding work show that the individuality of certain ears can be utilized in the improvement of a particular breed or variety. The breeding stock of Kansas Sunflower corn, after 4 years breeding by the station, traces back to 2 original mother ears.

Germination tests indicated that ears of corn may vary greatly in vitality, regardless of proper selection and preservation, and that it, therefore, is very important that each ear of seed corn be subjected to a germination test in order to remove those of low vitality.

Protein in seed corn, C. L. Penny (*Delaware Sta. Rpt. 1904–1906, pp. 13–33*).—Samples of seed corn were analyzed for the purpose of selective propagation. The percentages relate to the air-dry state after the corn had been kept over winter under the usual conditions.

For 59 crops grown in 4 different years the average of protein was 9.19 per cent, while the average for 50 crops grown from local seed was 9.14 per cent. With the exception of a few samples of shelled corn received from the West, which averaged 12.78 per cent protein, the highest percentage of protein was found in a Delaware crop, this being 11.22 per cent as an average of 36 ears chosen by the grower for physical perfection alone. The range in these ears was from 9.75 to 13 per cent, the best being about one-third better than the poorest. In another crop the range was from 6.25 to 12.69 per cent, the one being twice as rich as the other. The smaller kernels at the end of the ear were found to contain on an average 0.30 per cent less protein than the large and full-formed kernels. The results of the different crops are recorded in tables.

The value of cotton improvement (*Oklahoma Sta. Circ. 7, pp. 4*).—A popular discussion on the subject, mainly devoted to ways and methods of increasing the yield per acre.

Lupines as an intercultural crop for green manuring with potatoes, Hiltner (*Prakt. Bl. Pflanzenbau u. Schutz., n. ser., 5 (1907), No. 6, pp. 63–66, fig. 1*).—This article describes the growing of yellow lupines between the rows of potatoes for the purpose of soil improvement.

Rice culture, J. BOONACKER and A. W. DROST (*Inspectie Landb. West-Indië Bul. 8, pp. 35*).—This bulletin contains a description of rice culture in Surinam. Statistics of the industry are presented, the profits of rice growing given, and the methods of culture discussed.

On the continuous application of manganous chlorid in rice culture, II, K. ASO (*Bul. Col. Agr. Tokyo Imp. Univ., 7 (1907), No. 3, pp. 449–453*).—Earlier results in this line of work have been previously reported (E. S. R., 16, p. 42).

The data secured showed that liming increased the yield by 19 per cent. The manure and fertilizer application, increased by 33 per cent, gave an increase of 24.8 per cent in total yield. On the manganese plats the increase was relatively greatest when manuring conditions were the least favorable, the increase in total yield being 23.5 per cent. On the limed plats the manganese gave an increase of only 4.4 per cent. in total yield. On the heavily manured plat the manganese exerted no influence on the total production, but there was relatively more straw produced on the check plat than on the manganese plat. In the different years the increase in total yield through the action of manganese has varied from zero on the heavily manured plats of 1906 to 41.8 per cent in 1903.

The growth of sugar beet in the midlands, J. GOLDING and H. B. HUTCHINSON (*Abs. in Jour. Soc. Chem. Indus., 26 (1907), No. 10, pp. 512, 513*).—The results of cooperative experiments with sugar beets, which are here tabulated and discussed, indicate that complete commercial fertilizers while they maintain the quality also tend to increase the total yield of sugar per acre. Of the 4 varieties tested, Kleinwanzleben Original gave the highest yield of sugar. Stiff to medium loam soils proved most suitable to the crop, while bog soil was unsuitable. The best distance for planting in the rows was 12 to 16 in.

The progress in the beet-sugar industry during 1906, O. FALLADA (*Österr. Chem. Ztg., 10 (1907), No. 12, pp. 161–164*).—This article summarizes briefly the results of cultural and other agricultural experiments with sugar beets, of chemical studies and analytical methods of investigation, and of improvements in factory practices.

Sugar-cane experiments in the Leeward Islands, F. WATTS ET AL. (*Imp. Dept. Agr. West Indies, Sugar-Cane Expts. Leeward Isl., 1905–6, pt. 1, pp. 73*).—Descriptions of the varieties of sugar cane under test, together with the results secured, are given in tables. The experiments which have been in progress for several years are conducted on 8 estates in Antigua and 8 in St. Kitts. The total area occupied in both islands is 96 acres.

In Antigua the results with plant canes show that B.156, D.109, Sealy Seedling, B.208, B.376, Queensland Creole, and B.393 stand out as especially worthy of attention. Some of these canes have been mentioned in previous reports and B.208 and Sealy Seedling are recommended for fairly extensive planting. D.109, Sealy Seedling, and B.156 have also given best results as rattoons, the first cane possessing the rattooning power in a high degree.

In St. Kitts B.254 heads the list of averages with 8,072 lbs. of sucrose per acre. B.208, Sealy Seedling, D.109, and D.116 are recommended for trial by planters. The best results as rattoons were secured from White Transparent, D.95, and D.74.

Winter wheat varieties, J. H. BARRON (*Pennsylvania Sta. Bul. 82, pp. 19, figs. 8*).—The results of these experiments, which have been in progress for a series of years, indicate that there is no relation between straw yield and grain yield in wheat, that no single variety can be pointed out as the best, and that no specific date for sowing wheat can be given.

In 1906 Rural New Yorker No. 6 produced the smallest yield, an average of 28.91 bu. per acre, and Royal Red Clawson the largest, an average of 38.38 bu. per acre. The average yield of all varieties tested was 33.25 bu. per acre, the average yield of the smooth varieties 33.08 bu., and of the bearded varieties 33.59 bu. per acre. The average weight of all varieties was 60.75 lbs. per bushel, of the smooth varieties 60.43 lbs., and of the bearded 61.37 lbs. The average yield of straw per acre for each variety was 3,024 lbs.

In 1907 Dawson Golden Chaff ranked first with 38.23 bu. per acre and Martin Amber last with 26.26 bu. The average yield for all varieties was 31.35 bu. The smooth varieties gave an average yield of 32.19 bu. per acre and the bearded 29.68 bu. The average weight per bushel of all varieties was 62.65 lbs. The smooth varieties weighed 62.29 lbs., and the bearded 63.37 lbs. to the bushel. The average yield of straw for each variety this year was 4,342 lbs. per acre.

Judging from long year averages, which are considered best for determining variety qualities, Fulcaster, China, Royal Red Clawson, Reliable, and Dawson Golden Chaff have given the best results under conditions existing on the station farm.

The effect of shade during ripening on the proximate constituents of the wheat kernel, R. W. Thatcher and H. R. Watkins (*Jour. Amer. Chem. Soc., 29 (1907), No. 5, pp. 764–767*).—Analyses of wheat from shaded and unshaded plats showed that neither the moisture content nor the ash content was regularly affected. In 5 out of 6 cases the protein content of the shaded grain was higher. The starch content was decreased and the oil or ether extract slightly increased by shading, though this increase was very small.

"From this it appears that significant effects upon the percentage of protein and of starch in the kernels were produced by shutting off the direct rays of sunlight from the plants during the last 10 or 12 days of the ripening period. A careful study of the figures fails to reveal any exact relation between the decreased percentage of starch and the increased proportion of nitrogenous bodies. Hence it appears that the increase in the percentage of crude protein is not due simply to the failure of the plant to build up its normal amount of starch, but to some disturbance of the physiological processes caused by the absence of direct sunlight."

Dodder in relation to farm seeds, F. H. Hillman (*U. S. Dept. Agr., Farmers' Bul. 306, pp. 27, figs. 10*).—This bulletin discusses the importance of dodder as an impurity in seeds, describes the character of dodder plants, the various kinds of dodder and the kinds of seeds infested with it, points out the relation of dodder to the seed trade, and gives advice for buying seed and directions for cleaning the same.

Descriptions of the following dodder seeds are given: Flax dodder (*Cuscuta epilinum*), clover dodder (*C. epithymum*), small-seeded alfalfa dodder (*C. planiflora*), field dodder (*C. arvensis*), large-seeded alfalfa dodder (*C. indecora*), and Chilean dodder (*C. racemosa chilcana*).

HORTICULTURE.

Fruits and vegetables, E. B. Ferris (*Mississippi Sta. Bul. 101, pp. 4–11, fig. 1*).—The work at the McNeill substation with fruits and vegetables was continued along the lines of previous years (E. S. R., 18, p. 1127). Data are given in this report relative to the use of various combinations of fertilizers and marketing experiments with strawberries, asparagus, cabbage, Irish potatoes, and tomatoes.

With strawberries, 200 lbs. of cotton-seed meal, 200 lbs. of acid phosphate, and 100 lbs. of kainit were used as the unit application per acre as in the previous year. With this formula the yield of berries was 2,440 qts. per acre. When the cotton-seed meal and kainit were reduced one-half, the acid phosphate remaining as before, the yield was only 1,950 qts. per acre. Other combinations gave slight variations. The check plat yielded at the rate of 2,205 qts. per acre. The marketing of strawberries, principally at near-by cities, continues to be profitable. There were sold 199.5 24-qt. cases, which brought the shippers net returns of $426.25.

The fertilizer work with peaches was continued, but owing to the late spring freeze no satisfactory results were obtained. Owing to an outbreak of the San José scale all the trees in the variety orchard and in a commercial orchard planted to Greensboro peaches have been dug up and burned.

In the test with asparagus, nitrate of soda was used in the place of cotton seed. A mixture of 250 lbs. of cotton-seed meal, 125 lbs. of nitrate of soda, 405 lbs. of acid phosphate, and 170 lbs. of kainit was taken as the unit application per acre, and this formula gave a calculated yield of 1,396 lbs. of marketable asparagus per acre. When this formula was changed by either cutting down or omitting any of the ingredients, as well as when the unit application was doubled, the yield per acre was reduced. The check plat gave 952 lbs. per acre. It is thought that 1 row of the plat where the unit formula was used was favorably affected by manure applied to neighboring rose bushes. From the entire acreage devoted to this crop, 49½ boxes or 990 bunches were sold, netting $93.35. Chicago proved to be the best market.

The data secured with cabbage are also given, but the yields were unsatisfactory owing to the diseased condition of the plants, and the crop from the fertilized plats proved useless for market purposes. In addition to the plats included in the fertilizer test, an acre of land fertilized with 1,500 lbs. of decomposed cotton seed applied in the drill and listed upon, together with a mixture of 2 parts of acid phosphate and 1 part of cotton-seed meal applied at the rate of 1,000 lbs. per acre on top of the list and harrowed in, was planted with Jersey Wakefield cabbage on February 13. The plants were subsequently given two top dressings of nitrate of soda at the rate of 50 lbs. per acre each, and a fair yield of first-class heads was secured. Sixty-four crates netted $119.80, but the remaining 26 crates netted only $4.05 as they reached the market in poor condition. Some work was done in the fall planting of cabbage. With plants set out September 28, 1905, marketing began January 11, $40 worth of cabbage being sold from 0.22 of an acre. Cabbage set out in the fall of 1906, which survived the unfavorable planting season, made some good heads ready for market at Christmas. When well rooted the plants seemed to stand the lowest winter temperatures without injury, and when planted early in December it is stated that they not only make larger yields but sell for much better prices than when planted in February. The soils are so mellow that young cabbage plants have been successfully covered with dirt and carried through severe cold spells.

In the work with beans a mixture of 225 lbs. of cotton-seed meal, 112 lbs. of nitrate of soda, 456 lbs. of acid phosphate, and 200 lbs. of kainit per acre gave a calculated yield per acre of 130.6 bu. of beans on natural or unparked soil, and of 106.6 bu. on the parked area. When the kainit was omitted the results were 124.8 bu. on the natural soil and 118.7 bu. on the parked soil. With the exception of 1 year, beans have not proven a profitable shipping crop.

In the fertilizer test with Irish potatoes all yields are noted as too poor and irregular to be worth reporting. In a variety test, Triumph gave per acre 39.8 bu. of first grade and 3.5 bu. of second grade, Early Rose 100.8 bu. of first grade and 13 bu. of second grade, Burbank 96.8 bu. of first grade and 14.7 bu. of second grade, Peerless 104.5 bu. of first grade and 14.6 bu. of second grade. Triumph potatoes were dug on May 29 and the three other varieties on June 11. The Irish potato has not proven a profitable crop thus far, since the yield under the best conditions is only from 75 to 100 bu. per acre and unless placed on an early market the margin of profit is small.

Three-quarters of an acre of tomatoes was planted principally with the view of determining whether or not the crop can be raised successfully by spraying regularly to keep down black rot. Considerable rot was developed as the season advanced, but an application of Bordeaux mixture checked it almost entirely. One hundred and seventy 4-basket crates netted the shippers $94.67. It is concluded that tomatoes can be grown successfully in that region when spraying is regularly attended to.

Beets, onions, lettuce, and radishes are also said to do well and might be profitable if marketed properly and at the right time. On October 6, 1905, 0.17 of an acre of Egyptian blood turnip beets was sown, from which 27 bu. were sold during the early spring, netting the shippers $15.15.

Report of the horticulturist, C. P. Close (*Delaware Sta. Rpts. 1904–1906, pp. 40–48, 68*).—The principal lines of work conducted for the year 1906 consisted of experiments in apple breeding, comparative tests of spraying materials, fertilizers and cover crops, dipping nursery stock and strawberry plants in insecticides, and the pruning of Kieffer pears. The results of dust and liquid spraying and strong and weak Bordeaux on apples have been previously published (E. S. R., 18, p. 754).

The work in apple breeding is being carried on with the view of originating earlier varieties than those now existing, especally earlier red varieties. Several crosses were made between the well-known early sorts, between several of the winter sorts, and of some of the winter varieties with the early varieties. The methods of procedure are outlined, and the results are tabulated. Of the total number of crosses, 2,288, only 188 set fruit. Out of 871 blossoms bagged for pure breeding none set fruit. The crosses in which early varieties were used as female parents produced 1,129 good plump seeds. Only 1 fruit was secured out of the crosses where the winter varieties were used as female parents. This fruit contained 5 mature seeds. The seeds secured are to be grown to fruiting.

The work with commerical fertilizers and cover crops on apple orchards was continued (E. S. R., 18, p. 1043), but the author states that practically no results of a reliable nature have been obtained, as the cover crops have been too light. Somewhat similar tests have been conducted in a peach orchard, but owing to uncontrollable conditions and the diseased nature of the orchard, as well as to make room for apple trees in the same orchard, it has been decided to discontinue the test and remove the peach trees.

Dipping experiments with nursery stock and strawberries are noted elsewhere in this issue. A brief note is given on the present condition of the Kieffer pear trees with which pruning experiments were begun in 1903 (E. S. R., 18, p. 1043). Although the trees have not thus far produced as much fruit as trees of the same age unpruned, the author is of the opinion that the pruned trees will soon outyield the others.

Summary of investigations [Horticultural crops], J. G. Smith (*Hawaii Sta. Rpt. 1906, pp. 10–12, 14, 15, 17, pls. 2*).—A summary is given of planting operations and cooperative and marketing experiments with horticultural crops.

A tropical fruit orchard, including the mango, avocado, breadfruit, cherimoyer, sapodilla, wi, custard apple, longan, and others, has been planted, together with a nursery of citrus stock to provide material for budding and grafting, and a few acres of coffee and rubber trees. Two hundred cuttings of vanilla placed in a grove of Keawe have rooted nicely and are expected to bear in a year or more. An extensive cooperative experiment with wine grapes is being conducted on the island of Maui, in which 177 varieties are being tested.

Relative to coffee, it is stated that the chief cause of failure in Hawaii is due to economic conditions, as there are no difficulties about growing the crop. While the best grades have always been in demand the low grades can not be produced in competition with Brazil and similar countries, which tends to force the small producer out of business.

The cooperative experiments with cacao and bananas have been continued on the grounds of the Hilo boarding school. The growth of the cacao during the past year is reported as unfavorable, principally due to an unusual drought in a region which usually has abundant rain. Bananas planted for shade have grown well and some varieties have fruited.

Results of marketing experiments with horticultural crops have been previously noted (E. S. R., 19, p. 338).

Report of the horticulturist, J. E. HIGGINS (*Hawaii Sta. Rpt. 1906, pp. 33–36*).—Brief notes are given on the present status of citrus fruits and mangoes in Hawaii, together with some data on the distribution of Bluefields banana, roselle culture, and a partial list of plant accessions made during the year ending June 30, 1906.

Several varieties of lemons, together with superior limes and seedling pomelos are reported as growing in the gardens of Honolulu and other parts of Hawaii. An orange has recently been noted which has a decided tendency toward the navel type and lacks nothing in flavor. It is believed that by multiplying some of the native seedling oranges the fruit can be produced almost the whole year in most localities. A bulletin dealing with the culture of citrus fruits in Hawaii was published in the early part of the year and previously noted (E. S. R., 17, p. 767).

As has been previously noted in a bulletin on the mango in Hawaii (E. S. R., 17, p. 1155), the presence of the mango weevil (*Cryptorhynchus mangiferæ*) is said to be the one serious hindrance to the progress of the industry. A plea is made for more stringent measures to control and destroy this insect. A collection is being made of the finest varieties of mango trees available, and these will be propagated on seedling stock.

Experiments conducted with the roselle show the plant to be well adapted to local conditions. The yield of fruit per acre under average conditions is given as from 6,000 to 7,000 lbs. The fleshy calyx and the seed pod while young and tender are said to make an excellent jam and jelly. While fairly tolerant of dry weather, it is stated that the plant improves and produces more heavily with irrigation. The seed is sown about March, and the plants set in the field when from 6 to 8 in. high. Planting distances recommended are 4 by 6 ft., where either irrigation is to be employed or rainfall is abundant, and about 4 by 4 ft. in dry localities.

Cantaloupes, P. K. BLINN (*Colorado Sta. Bul. 121, pp. 6–8, figs. 3*).—The author has succeeded in developing a cantaloupe with rust-resisting qualities. Seeds were distributed to various sections in the United States, and brief extracts are given from the reports thus far received.

In the majority of cases this melon has given good satisfaction and the fruit and vines have held up long after other varieties were attacked by the rust. A record is also given of the author's trials with this seed during the past season, from which it appears that the rust-resistant selection remained green until the majority of the fields were dead. Some of the most markedly resistant plants in the plat remained green until frost, in spite of the fact that the seed was grown on soil that for 4 consecutive years had been badly infested with rust.

The apparent lateness of the rust-resistant strain of melon is believed to be due to abnormal ripening of the other strains rather than to any real inherent lateness. In order to develop early maturity in the rust-resistant strain, however, arrangements are being made for a cooperative test in which some of the seed will be grown in Canada and the product then tested at Rocky Ford to indicate the influence of latitude on early maturity.

Tomato culture, W. W. Tracy (*New York, 1907, pp. X+150, pl. 1, figs. 43*).—This is a practical treatise on the tomato, including its botany, history, general characteristics, planting, fertilization, cultivaton in garden and greenhouse, harvesting, packing, storing, and marketing. Consideration is also given to the adaptation of varieties for different purposes, and to seed breeding and growing, together with chapters on insect enemies and their control by F. H. Chittenden, and the diseases of tomatoes and their control by W. A. Orton.

A method of propagating fruit trees with special reference to the olive, Dubouloz (*Bul. Off. Gouvt. Gén. Algérie, 13 (1907), No. 15, p. 232*).—The author calls attention to the successful results secured from propagating the olive by what he terms the graft-cutting ("greffe-bouture") method. This method, which is described, appears to be similar to the long scion root-graft method used chiefly with apples in the western part of the United States, in which the grafted scion is planted up to the top bud and eventually forms roots, being nourished in the meantime by the piece of root to which it is grafted.

The cherry in the valley of the Rhone, A. Cadoret (*Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), Nos. 27, pp. 20–25; 28, pp. 42–52, figs. 10; 29, pp. 86–90; 30, pp. 119–123; 31, pp. 142–148*).—Popular directions are given for the cultivation of the cherry with special reference to the development of the industry in the valley of the Rhone. All of the important phases are considered, including soil and climatic conditions, varieties, soil preparation, and planting operations, pruning, fertilizing, enemies of the cherry and their control, harvesting and marketing. Information is also given with regard to yields, financial returns, market conditions, and the various uses of the cherry.

New hybrid plum, A. M. Ragland (*Farm and Ranch, 26 (1907), No. 26, p. 10, fig. 1*).—A description, with illustration, is given of a new hybrid plum said to have originated in the orchard of H. A. Biles, of Roanoke, Tex. This plum, which has been named Bilona, is believed to have originated accidentally through cross-pollination of the Chabot by a wild plum growing in a neighboring forest. It is said to have the form of the Chabot, blooming at the same time, and bearing an immense crop of fruit, which is covered with a crimson blush on a yellow ground and a heavy bloom, characteristic of the Australis, a native wild plum of that section. The tree is said to have an upright and vigorous growth, and the fruit is believed to be equal in quality to the best plums of Americana or Chickasaw strains.

Coffee culture in Hawaii, W. H. Ukers (*Tea and Coffee Trade Jour., 13 (1907), No. 2, pp. 67–75, figs 15*).—A popular account of the coffee industry in Hawaii, including considerable data with regard to the annual yields, value, acreage, average yield, cost of production, and the estimated yield for the islands. The annual output is given as from 24,000 to 30,000 bags exported to the mainland, together with 1,800 to 2,000 bags consumed in the islands. The annual value for the 5 years 1901–1906 ranges from $270,000 to $336,000. The total acreage under cultivation is given as 4,500, the average yield about 650 lbs. per acre, and the average cost of production in 1906 as 7½ cents per pound. The average selling price is 10½ cts. per pound. The text is well illustrated.

Home grown tea, G. F. MITCHELL (*Tea and Coffee Trade Jour., 13 (1907), No. 2, pp. 76–80, figs. 4*).—This is a reproduction of a Farmers' Bulletin on the same subject recently published by the author and noted (E. S. R., 19, p. 240).

Breeding hardy strawberries, N. E. HANSEN and C. HARALSON (*South Dakota Sta. Bul. 103, pp. 218–265, figs. 20*).—In 1894, an experiment was begun at the Iowa Station by the late J. L. Budd, assisted by N. E. Hansen, in improving the wild strawberry of Manitoba by crossing with standard cultivated varieties. The experiment was subsequently dropped, as it was found (E. S. R., 10 p. 47) that although the resulting hybrids were hardy the fruit was too small to compete with standard market varieties. Owing to the general complaint as to the lack of hardiness of standard varieties in the Northwest prairie regions, however, this experiment has been continued and enlarged at the South Dakota Station, with a view to producing varieties perfectly hardy without winter protection of any kind. An account is given of the work conducted at the station along this line.

Native varieties were brought together from different sections in the Northwest and grown with a large number of cultivated varieties with a view of comparing their relative hardiness. Of the cultivated varieties Princess, Warfield, Clyde, Enhance, Van Deman, Bederwood, Bisel, Seaford, and Glen Mary made the best showing in the order named. None of these varieties, however, were as hardy as the native wild strawberry. An attempt has been made to improve the latter both by hybridization and selection.

Out of several thousand hybrid seedlings 225 were saved for further trial and have since been largely reduced in number. Only 2 have been sent out for preliminary trial, South Dakota No. 1 and South Dakota No. 2. Extracts from the reports on these varieties show that they are of promise only where standard varieties suffer from the cold winters. A large number of derivative hybrids have also been made between the primary hybrids and choice cultivated varieties. About 100 primary hybrids, together with 22 of the more promising secondary hybrids are shown in a series of plates with notes on their parentage.

Breeding experiments with the wild strawberry of Alaska have been started, as a result of which several hundred vigorous hybrid seedlings came into bearing this year. The wild Alaska strawberry is larger than the native Northwestern prairie strawberry.

In addition to the work at the station a list is given of commercial varieties grown in the southeastern part of the State, with notes on their value, representing the experience of leading commercial growers in Vermilion, together with notes on varieties and methods of culture in the Black Hills, by F. L. Cook. Introductory remarks deal with how new strawberries are invented, perfect and imperfect strawberry blossoms, pedigree strawberry plants, historical notes on wild American strawberries, origin of our cultivated strawberries, and winter-killing.

Raspberries, blackberries, and dewberries, N. E. HANSEN and C. HARALSON (*South Dakota Sta. Bul. 104, pp. 266–297, figs. 15*).—In this bulletin a series of 15 plates is given illustrating the work in raspberry breeding at the South Dakota Station, in which are shown over 140 seedling varieties that have proven hardy without protection. The text of an address on breeding hardy raspberries for the Northwest, delivered before the American Breeders' Association (E. S. R., 18, p. 940), is reproduced, the classification of raspberries is briefly discussed, and notes are given on a large number of varieties of raspberries, blackberries, and dewberries tested, including hybrid raspberries produced at the station with special reference to hardiness.

In 1906, 325 seedlings, almost all hybrids, were selected from a large plantation of seedling raspberries produced at the station and have been planted for further trial. Several of these seedlings are said to be very large in size and very productive. Extracts are given from a report on the brambles in the Black Hills made by F. L. Cook to the South Dakota State Horticultural Society, in which it is stated in substance that blackberries, black-cap raspberries, and the hybrid raspberries of the Columbian type produce on the average only half a crop and are unprofitable commercially. Of a large number of varieties of red raspberries tested in the same region, Loudon and Marlboro are strongly recommended for planting, having proven for a number of years more than twice as productive as any others. "Dewberries are productive, but only an expert will be able to make them pay for market."

The authors are of the opinion that it is useless to expect anything of value from cultivated varieties of raspberries, blackberries, and dewberries upon the open prairies of the Northwest, and that an attempt must be made to cultivate and improve native forms of these fruits.

Roselle: Its culture and uses, P. J. Wester (*U. S. Dept. Agr., Farmers' Bul. 307, pp. 16, figs. 6*).—This bulletin deals with the history and geographical distribution of the roselle, together with its botanical characters and relationships, varieties, cultivation and fertilization, yield, harvesting, marketing, composition and uses of the fruit and plant, and notes on breeding, fungus diseases, and insect enemies.

The roselle is an annual from the Old World tropics. Its principal use is for the making of jellies, jams, etc., from the calyces of the fruit, although the young stems are also said to make good jelly, and the plant is said to be grown in India for its fiber, which is used in the manufacture of cordage and coarser textile products. On account of its extreme sensitiveness to frost it is here recommended for cultivation for its fruit only in tropical and subtropical countries.

Fruit growers' associations, W. Paddock (*Colorado Sta. Bul. 122, pp. 18*).—In this bulletin the author describes the workings of the fruit associations in Colorado, including all the important phases of organization methods. A list is given of 33 fruit and produce and cantaloupe associations now doing business in the State.

As an example of successful cooperation a brief history is given of the Grand Junction Fruit Growers' Association, which was started in 1891, and is doing the largest business of any in the State, together with a statement of the business transacted in 1906, the by-laws, and the grading list of this association. In 1906 a total of 1,036 cars were shipped. The gross receipts were $814,278.62, and the amount paid growers $555,813.44

FORESTRY.

Investigations on the comparative value of various substances for the preservation of wood, E. Henry (*Bul. Soc. Sci. Nancy, 3. ser., 8 (1907), No. 1, pp. 42–139, pls. 10*).—The author here reports the results of 3 years' experiments at the forest school at Nancy along the above lines, in which a large number of antiseptics were tried on various species of wood used for construction purposes, the object of the experiments being to obtain reliable data for the use of architects, contractors, etc., both with regard to the most efficient and economical preservatives and their method of application.

The author briefly reviews the work of other investigators, after which his experiments, together with the results secured, are discussed in detail. The treated wood has been tested for the 3 years under various conditions, both in the open air and under cover, in contact with soil, garden compost, stable manure, and on planks infected with fungus diseases. Although the present experiments are not considered complete and are to be continued for several years, the results so far indicate that the carbolineum preparations, as well as microsol, are the best preservatives to use. Gas tar also proved quite efficient, but antinnonine, antigermine, lysol, and hydrofluoric acid were of little value. Microsol is believed to be more adapted for the preservation of wood used for interior work, since it neither stains the wood nor gives off an unpleasant odor.

Descriptions are given of a large number of fungus diseases and insect pests attacking wood, together with suggestions for their control, and a bibliography of important literature on this subject.

The comparative durability of oak and beech railroad ties is discussed. The creosoted beech is said to be more durable even than the heartwood of the creosoted oak. Consideration is also given to the methods of application, the qualities of a good antiseptic and the facility of impregnation of various hardwoods and conifers with carbolineum avenarius, with special attention to the beech both on account of its abundance and importance as a commercial wood, and because of its proneness to decay when untreated.

The text is accompanied by several plates showing the effect of various preservatives on the wood treated.

The article concludes with a contribution by M. Mer on the value of barking or ringing trees some time previous to cutting in order to prevent decay. Experimental work along this line is noted to show that barking the tree renders the sapwood more durable and less subject to fungus attack.

The strength of wood as influenced by moisture, H. D. Tiemann (*U. S. Dept. Agr., Forest Serv. Circ. 108, pp. 42, figs. 6*).—In order to secure data with regard to the physical effects of moisture upon woods, an investigation has been conducted at the Yale Forest School laboratory during the past 3 years in which several thousand mechanical tests were made on specially prepared material. The principal species tested were longleaf pine, red spruce, and chestnut. The main tests were made in compression parallel to the grain, bending, shearing, and compression at right angles to the grain. The methods of conducting the tests, together with the principal results secured, have been previously described (E. S. R., 18, p. 743).

The present circular contains a summarized statement of the results obtained both with the species above named and with subsequent tests upon loblolly pine, red gum, Douglas fir, Norway pine, and tamarack. The results are further explained by numerous tables and graphical diagrams. Among the phases here considered are the fiber-saturation point, a summary of moisture-strength relations, shrinkage, effect of casehardening, effect of the process of drying upon wood, and effect of superheating. The equation for the moisture-density-strength relation for longleaf pine, as well as numerous moisture-strength reduction tables for the various species tested, are also given.

Observations on the influence of frost on the diameter of living trees, J. Friedrich (*Centbl. Gesam. Forstw., 33 (1907), No. 5, pp. 185–192*).—The author has conducted investigations for a great many years concerning the influence of weather and climate on tree growth. The reports on this subject, published in 1897, have been noted (E. S. R., 9, p. 562).

In the present report a brief account is given of the author's investigations on the influence of frost upon the diameter of living trees, and the results are presented in tabular and graphical form. Actual measurements were taken of several trees twice daily from December 15, 1905, to February 17, 1906. The time of observation, temperature, and variation in diameter are indicated.

Investigations on the distribution of native woody plants in the canton of Geneva, Switzerland, A. LENDNER (*Recherches sur la Répartition des Plantes Ligneuses Croissant Spontanément en Suiss. Berne, Dept. Int.* [*1907*], *pp. XVI+63, fig. 1, maps 2*).—This is part 1 of a series of publications to be issued on the native ligneous plants growing in Switzerland and edited under the direction of the federal inspection of forests at Berne and of the botanical museum of the government polytechnic school of Zurich. Some general statements are given on the geology and soil formation in Geneva, together with an enumeration of the occurrence of various species of trees and other woody plants in the canton and methods of culture. The region of the distribution of the more important trees is illustrated by 2 maps.

A new tree juniper for New Mexico (Juniperus megalocarpa), G. B. SUDWORTH (*Forestry and Irrig., 13* (*1907*), *No. 6, pp. 307–310, figs. 2*).—Aside from their economic forest work, the members of the forest survey are making a careful scrutiny of trees wherever found, for the purpose of determining their limits of range.

W. R. Mattoon, of the Forest Service, recently collected notes, photographs, and specimens which enabled the writer to distinguish what is said to be an unique species of juniper. At present this species, which has been named *Juniperus megalocarpa*, is known to occur only in the Gila national forest of New Mexico, where 20 to 30 trees were found grouped together.

Descriptions, with illustrations, are given of the tree, including the trunk, foliage, fruit, and seed.

Forest planting in the North Platte and South Platte valleys, F. G. MILLER (*U. S. Dept. Agr., Forest Serv. Circ. 109, pp. 20*).—In this circular consideration is given to topography, soil, climate, and purposes of forest planting, together with lists of species recommended for planting in both valleys and for experimental purposes, species best adapted to different uses, and notes on planting, cultivation, and subsequent management. The circular concludes with brief descriptive and cultural notes on the various species recommended for planting.

Silvical leaflets (*U. S. Dept. Agr., Forest Serv. Silv. Leaflets, 1, pp. 3; 2, pp. 3; 3, pp. 4; 4, pp. 4; 5, pp. 3; 6, pp. 4; 7, pp. 2; 8, pp. 3; 9, pp. 4; 10, pp. 3; 11, pp. 3; 12, pp. 2; 13, pp. 4; 14, pp. 4*).—A series of leaflets, each one dealing with the range and occurrence, climatic adaptability, habit, associated species, soil and moisture, tolerance, and reproduction of one of the following species of trees, given in order to correspond to the leaflet numbers above: Alpine fir (*Abies lasiocarpa*), Port Orford cedar (*Chamæcyparis lawsoniana*), Engelmann spruce (*Picea engelmanni*), white fir (*A. concolor*), lowland fir (*A. grandis*), Sitka spruce (*P. sitchensis*), noble fir (*A. nobilis*), red fir (*A. magnifica*), incense cedar (*Libocedrus decurrens*), bigcone spruce (*Pseudotsuga macrocarpa*), giant arborvitæ (*Thuja plicata*), yellow cedar (*C. nootkatensis*), western white pine (*Pinus monticola*), and western larch (*Larix occidentalis*).

How and when to collect white pine seed, F. W. RANE (*Boston, 1907, pp. 16, figs. 3*).—In this booklet the author considers in a general manner the life history of white pine seed and gives popular directions on how and when to collect the seed and the method of extracting it from the cones, which should be gathered before they open.

The demand for white pine seed is active and prices in recent years are said to have ranged from $1.50 to $4.50 per pound. The purpose of this pamphlet is to call attention to the importance of gathering the seed each fruiting year, with a view to stimulating forest planting operations and reducing the prevailing price of seed.

Annual report on the forest administration in Ajmer-Merwara for 1905–6, N. Mal (*Ann. Rpt. Forest Admin. Ajmer-Merwara, 1905–6, pp. 39*).—This is the customary report of the forest administration in Ajmer-Merwara for the forest year 1905–6, including the constitution, management, and protection of State forests, silvicultural operations, exploitation, and the financial statement for the year. The important features of the work are tabulated.

Progress report of the forest surveys in India for 1905–6, P. J. Gordon (*Rpt. Forest Surveys India, 1905–6, pp. 19, map 1*).—This report includes tabular statements with notes of the forest survey operations in the various provinces of India for the survey year ending September 30, 1906, and is accompanied by a map illustrating the extent of forest surveys in India.

National arboretum of Barres [France], L. Pardé (*Arboretum National des Barres. Paris, Lib. Sci. Nat., 1906, pp. 397, pls. 94, dgms. 21*).—This work consists of an enumeration of the native and exotic species of trees grown in the forest domain of Barres. The origin, synonyms, and distinguishing characters are all indicated, together with a brief discussion as to the requirements and value of each for forestry purposes in France. The text is well indexed, and a large number of the species described are illustrated. Several plans are also given showing the different sections of the arboretum, together with lists of the authors and publications consulted and cited.

Experiments on rubber tapping, W. Peel (*Agr. Bul. Straits and Fed. Malay States, 6 (1907), No. 4, p. 107*).—The results of a series of rubber-tapping experiments carried on during the past year at the Singapore and Penang botanical gardens are presented in tabular form.

One old Para tree was tapped 14 times between November 19 and December 15, and yielded 4 lbs. 4½ oz. of dry rubber, making a total of 35 lbs. 13½ oz. from this tree since it was first tapped. Four other 12-year old trees, tapped 14 times between July 11 and August 6, yielded a total of 6 lbs. 6 oz. of dry rubber.

Camphor production in Formosa and China, J. H. Arnold and S. L. Gracey (*Daily Consular and Trade Rpts.* [*U. S.*], *1907, No. 2899, pp. 1–5*).—According to Consul J. H. Arnold, of Tamsui, camphor production in Formosa is confined to trees at least 50 years of age, the cutting down of trees of a less age being prohibited by the government. Recent investigations are said to warrant the statement that the supply of old trees will at the present rate of cutting become exhausted in less than 50 years. Owing to poor sanitary conditions, lack of roads, and the presence of head-hunting tribes of savages, much of the material in Formosa may not be harvested for years. During the present year the Formosa camphor bureau, which controls almost a complete monopoly in the production and sale of the world's supply of camphor, expects to produce 6,667,000 lbs. of crude camphor, and about one-half of that amount of camphor oil.

A brief account is given of the work of afforestation being conducted under the initiative of the government, together with the process of camphor manufacture, and some notes on marketing the product.

Consul Gracey, of Fuchau, reports that in China the camphor trees are being ruthlessly cut down as fast as they can be bought from the owners. A special tax is to be imposed on the camphor and camphor oil produced, which will be expended in planting and cultivating new trees. Five young trees are to be planted for every tree cut down.

DISEASES OF PLANTS.

Report of assistant mycologist, H. S. JACKSON (*Delaware Sta. Rpts. 1904–1906, pp. 70–77, pls. 2*).—Considerable attention was paid by the author to a number of diseases of plants, and notes are given on sun scald and bacteriosis of plums, fire blight of apples, blight of cantaloupes, double blossom of blackberries and dewberries, and anthracnose of peppers.

The author's attention was called in the fall of 1905 to a trouble of fruit trees, affecting plums in particular. The disease was indicated by the cracking of the bark on the trunk of the tree, usually near the ground, though in some cases extending to the first branches. Investigations were carried on to ascertain whether any fungus or other organism was associated with this trouble, and the conclusion is drawn that it was not due to any specific organism. It is thought to have been a true sun scald caused by the alternate freezing and thawing in the spring of the year, and suggestions based upon the experience of other investigators are given for the treatment of the wounds.

The fire blight of the apple was investigated, and the disease was recognized as due to the same organism as that causing the fire blight of the pear. The observations made indicated that the infection is very largely through the blossoms and that not infrequently the bacteria spread from one fruit to another in the cluster through the peduncles. In several cases the organisms were isolated from the decaying peduncles, and cultures made of them successfully inoculated both apple and pear twigs.

The blight of cantaloupes described is that due to *Macrosporium cucumerinum*, a full account of which has already been given (E. S. R., 14, p. 260). Attention is called to the efficiency of Bordeaux mixture when properly applied in preventing this disease and recommendations are made for its use.

In 1905 the attention of the mycologist of the station was directed to a disease of plums locally known as bacteriosis. This disease first makes its appearance as dark sunken areas on the younger twigs, which gradually spread, and, as the twig grows, become cracked, enlarging to form a small canker. The disease is not confined to the bark, but extends into the wood, and appears to start only on the first year's growth. Cultures from diseased spots gave abundant colonies of bacteria, and a number of successful inoculations were made from them. It appears from the preliminary study that this disease is of bacterial origin, although the evidence is not yet considered conclusive. It is not known as yet whether this disease is in any way connected with the bacterial spot of the fruit, due to *Pseudomonas pruni*, but it is thought that it is not the same as that reported by Jones as due to the pear blight organism (E. S. R., 14, p. 880).

Attention is called to the occurrence of double blossoms of blackberry and dewberry, in which there is an abnormal increase and change in the form of the flower parts as well as in the number of branches. The stamens and pistils are usually infertile, consequently no fruit is set. The disease may be detected when the buds are opening, and it is suggested that all canes showing the evidence of formation of rosettes or double flowers should be pruned and burned.

An anthracnose of Cayenne peppers was noticed on truck farms. The disease was found to be due to the fungus *Colletotrichum nigrum*, which is known to affect the ordinary varieties of red peppers. Spraying the plants with Bordeaux mixture or ammoniacal copper carbonate as the fruit approaches maturity is recommended.

Report of the section of seed control, Hohenheim, 1906, O. KIRCHNER (*Württemb. Wchnbl. Landw., 1907, No. 17, pp. 347–353*).—The principal investigations during the year have been studies of the susceptibility of varieties of wheat to smut and rust, the diseases and insect enemies of clovers, various garden and orchard crops, forest trees, and ornamentals, and the means for their repression. Studies are also reported upon various weeds, a number of which were successfully destroyed by spraying the fields with 15 to 25 per cent solutions of iron sulphate. This treatment was especially efficient in destroying wild mustard and wild radish.

Sprout infection by smuts, L. HECKE (*Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 6, pp. 572–574*).—As a result of his experiments the author claims that in addition to smut infection through the flowers and seedlings, a third method must be recognized, in which the infection takes place through the young shoots, and probably in the case of cereals through the stooling shoots of the plant. He thinks this method of infection quite common for *Ustilago violacea* and *Urocystis occulta* and possibly other species of smuts.

New species of fungi, C. L. SHEAR (*Bul. Torrey Bot. Club, 34 (1907), No. 6, pp. 305–317*).—Technical descriptions are given of the following new species and varieties of fungi discovered by the author on the leaves and fruits of the cranberry: *Cladosporium oxycocci* n. sp., *Helminthosporium inæquale* n. sp., *Phyllosticta putrefaciens* n. sp., *Sphæronema pomorum* n. sp., *Septoria longispora* n. sp., *Sporonema oxycocci* n. sp., *S. pulvinatum* n. sp., *Plagiorhabdus oxycocci* n. sp., *Leptothyrium oxycocci* n. sp., *Rhabdospora oxycocci* n. sp., *Ceuthospora (?) lunata* n. sp., *Anthostomella destruens* n. sp., *Acanthorhynchus vaccinii* n. sp., *Glomerella rufomaculans vaccinii* n. var., *Glœosporium minus* n. sp., and *Guignardia vaccinii* n. sp. The last species is said to be the cause of the serious cranberry scald, first described, but without name, in Bulletin 64 of the New Jersey Stations (E. S. R., 1, p. 263).

In addition other species of fungi are described, among them *Ozonium omnivorum* n. sp. from cotton roots. This fungus is said to occur from eastern Texas to southern California and is a facultative parasite infesting the soil and attacking the roots of a great variety of plants, causing serious damage to such cultivated crops as cotton, alfalfa, cowpeas, sweet potatoes, beets, and fruit trees. The cotton root rot hitherto attributed to *O. auricomum* is said to be due to *O. omnivorum*, and while the other species occurs in Texas, so far it has been observed only as a pure saprophyte.

New and additional species of fungi, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1907, No. 6, pp. 238–244, pl. 1*).—A list of the species of fungi observed by the author in the Kew Gardens is given. Among the species mentioned are the following parasitic forms: *Pyrenochæta phloxidis* n. sp. occurring on phlox, *Ascochyta cookei* n. sp. on sweet william, and *Ramularia necator* n. sp. on the cotyledons of seedling cacao.

P. phloxidis was quite destructive to a bed of phlox, the foliage first assuming a greenish-yellow color, and afterwards wilting and falling to the ground, followed by a breaking of the stems near the base. The species of Ascochyta resembles *A. dianthi*, but differs in some very important characters. The species of fungus on the cacao was observed on the cotyledons of plants grown from seeds recently obtained in Jamaica. It proved to be truly parasitic and quite destructive, and the author raises the question whether this fungus has been observed as a parasite on cacao seedlings in Jamaica.

Celery root rot, J. M. VAN HOOK (*Ohio Sta. Circ. 72, pp. 6, figs. 3*).—In 1904 a serious root rot of celery was reported from a number of districts in Ohio, the affected plants being characterized by a decay of the main roots, leaving only the crown, usually in the form of an inverted cone, so that the plants are readily lifted from the ground. The remaining portions of the root are black or brown in color, and the disease is found to extend to the bases of the outer leaf stalks, which after infection die. The decay of the roots is usually complete. In some cases, particularly among young plants, new roots appear, but the plants never attain full size or wholly recover from the injury.

So far as the writer knows, this disease, which seems quite distinct from black rot or heart rot, has never been described.

The disease appeared in soils in which celery had been grown for many successive years, and a species of Rhizoctonia was found on many of the roots. A careful study of the fungus led the author to believe that it was not wholly responsible for the trouble, at least not in the beginning, nor could any bacteria or other organisms be found constantly associated with it. The diseased spots in the fields always seemed to be where the ground was slightly lower or not well drained, and it seems clear that soil conditions were responsible for a considerable portion of the trouble. It is believed that poorly drained soils are the primary cause of this root rot and that the Rhizoctonia is associated with it only in the later stages of decay.

Potato spraying experiments in 1906, F. C. Stewart et al. (*New York State Sta. Bul. 290, pp. 239–321, pls. 2*).—This is a report of the fifth year of the 10-year series of potato spraying experiments begun in 1902. The experiments were carried out on the same lines as previously indicated (E. S. R., 18, p. 52), 80 separate experiments being reported in this bulletin.

At Geneva, 5 sprayings increased the yield 63 bu. per acre, while 3 sprayings increased it 31.75 bu. The gain is said to be due chiefly to the prevention of the late blight. At Riverhead the gain due to 5 sprayings was 53.25 bu. per acre and to 3 sprayings 21.5 bu. Here the chief enemies were the flea-beetle and the late blight. No rot was observed at either station.

In the farmers' business experiments, in 15 experiments, including 225.6 acres sprayed 5 or 6 times, the average gain due to spraying was 42.6 bu. per acre. The total cost of spraying was $5.18 and the average net profit $13.89 per acre.

In the volunteer experiments, 62 experimenters sprayed 598 acres and report gains averaging 44.5 bu. per acre, the largest being 132.6 bu., while 2 report no gain whatever.

Five years of potato spraying, F. H. Hall et al. (*New York State Sta. Bul. 290, popular ed., pp. 12*).—A popular edition of the above.

The nature and control of blackleg of potatoes, Kleberger (*Ztschr. Pflanzenkrank., 17 (1907), No. 2, pp. 80–83*).—The blackleg of potatoes is said to spread from the seed tubers to the stems and young tubers, causing their destruction. The direct infection of the stems seems to be also probable. A large amount of humus in the soil or heavy applications of stable manure favor the development of the disease, and early and medium varieties of potatoes are more subject to it than those maturing late in the season. The disease in the field may spread from plant to plant, the rapidity of the spread depending on the distance separating the plants as well as the amount of humus in the soil.

Soaking seed potatoes in fungicides before planting was tested, and as a result a 2 per cent Bordeaux mixture solution is recommended as more efficient than corrosive sublimate in controlling the disease.

A disease of peas and beans, P. Masseron (*Semaine Agr. [Paris], 26 (1907), No. 1370, p. 270; noted in Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), No. 35, p. 267*).—An account is given of a sclerotium disease of peas and beans, which is due to the fungus *Sclerotinia libertiana.*

This disease was especially destructive in certain regions in France during the spring of 1907. Its unusual development is said to be due to the intensive culture of peas, that crop being frequently grown successively upon the same soil, and also to favorable conditions of humidity and temperature. The fungus is said to attack peas, beans, Jerusalem artichokes, ruta-bagas, carrots, beets, maize, and hemp.

In order to prevent its destructive occurrence, it is recommended that rotations should be followed so that for a period of at least 4 years susceptible plants should not occupy the soil. In addition the débris of all diseased plants should be collected and burned and not scattered over the soil, as is the common practice.

A disease of peanuts, A. Zimmerman (*Pflanzer, 3 (1907), No. 9, pp. 129–133*).—An account is given of a disease of peanuts in German East Africa by which about 10 per cent of the plants were destroyed. The cause of the disease is not definitely determined, but it is believed to be similar to those producing the mosaic disease of tobacco, leaf curl of cassava, and infectious chlorosis of a number of mallows.

Preliminary note on a new disease of the cultivated vetch, G. F. Atkinson and C. W. Edgerton (*Science, n. ser., 26 (1907), No. 664, pp. 385, 386*).—In July, 1906, the attention of one of the authors was called to a fungus disease of the cultivated vetch, which does not seem to have been reported. It was first observed on stems and pods in the horticultural grounds of Cornell University and was later brought to the laboratory from fields of vetch growing on the university farm.

The disease appeared quite abundant and was often associated with an Ascochyta, especially on the stems. Here the fungi are often mixed together, so that it is probable that they would be confused. When occurring on the pods the disease is easily distinguished with the unaided eye, as the gross appearance of the spots and spore pods are very striking. The spots are elongated, forming either long narrow or elliptical spots, sometimes with a dull purple border. The spots on the pods are oblique, probably due to the oblique fibrous structure of the pods. The middle line of the spot is white from the numerous spores formed on the basidia, which later ooze out in masses.

In the case of the Ascochyta the spots are nearly always circular, and grayish in color, with a dull purple border.

The fungus appears to be the type of a new genus for which the name *Protocoronospora* is proposed. The species *P. nigricans* n. sp. is provisionally described.

The parasitism of Neocosmospora, E. F. Smith (*Science, n. ser., 26 (1907), No. 663, p. 347–349*).—This is a review and criticism of the experiments and conclusions of H. S. Reed upon the parasitism of this fungus (E. S. R., 18, p. 152).

Apple mildew, E. S. Salmon (*Gard. Chron., 3. ser., 42 (1907), No. 1079, p. 166*).—A note is given on the occurrence of apple mildew (*Podosphæra leucotricha*), which it is stated has attacked the fruit in the orchards connected with the agricultural college at Wye, England. In all cases observed the leaves and fruit of the trees were attacked, but as yet no serious injury has been introduced. In many cases the parasitic fungus *Ampelomyces quisqualis* had attacked the mildew and would no doubt greatly retard its spread.

Attention is called to the fact that the apple mildew is sometimes erroneously called *Spærotheca mali*.

The relation of twig cankers to the Phyllosticta apple blotch, W. M. Scott and J. B. Rorer (*Reprinted from Proc. Benton Co. [Ark.], Hort. Soc. 1907, pp. 6*).—According to the authors, the blotch disease due to Phyllosticta was first reported in a bulletin of the Illinois Station (E. S. R., 13, p. 1089). Since that time the disease has become more widely spread and is now recognized as one of the most destructive of the apple fruit diseases in Arkansas.

During the progress of these investigations there were noticed on the fruiting branches and other shoots, particularly the water sprouts, numerous cankers, which contained spore-bearing pycnidia. An examination of these cankers and inoculation experiments have shown the identity of the fungus, so that it seems certain that the same species produces blotches on the fruit, cankers on the twigs, and spots on the leaves.

In connection with spraying experiments for the control of orchard diseases, the authors have found that apple blotch can be readily prevented by thorough spraying with Bordeaux mixture. As the fungus winters over in the cankers on the twigs, it is believed that by thorough spraying for two or three years, it could be practically eliminated.

The gummosis of the Amygdalaceæ, A. RANT (*Inaug. Diss., Amsterdam, 1906; abs. in Ztschr. Pflanzenkrank., 17 (1907), No. 3, pp. 179, 180*).—The author gives a review of the theories of gum formation, after which he describes the anatomical changes associated with it. He claims that a distinction should be made between the gum that is formed within the cells and that in the intercellular spaces. Only the intercellular formation of gum gives rise to the phenomena associated with the disease known as gummosis.

The formation of gum in the intercellular spaces is said to be due to the development of new tissues, the lignification of tissues, and the activity of wounded cells. The activity of the wounded cells is often caused by attacks of bacteria, fungi, and boring insects. Among the more common fungi are *Clasterosporium carpophilum* and *Coryneum beijerinckii*. *Cytospora leucostoma*, or *Valsa leucostoma*, is less important but causes the peculiar gummosis of cherry trees that is characterized by the accumulation of gum under the bark. Species of Monilia also cause gummosis of various stone-fruit trees, and *Botrytis cinerea* produces the disease on cherry trees. Bacteria are also said to cause this disease.

Concerning the origin of the gum on cherry trees, K. MIKOSCH (*Sitzber. K. Akad. Wiss.* [*Vienna*], *Math. Naturw. Kl., 115 (1906), No. 6, pp. 911-961, pls. 4*).—A discussion is given of the origin of the gum that accompanies the disease of cherries known as gummosis. This gum is considered a pathological product and follows wounds of the cambium, its formation taking place within the inner portions of the cambium layer.

A peach disease (*Gard. Chron., 3. ser., 42 (1907), No. 1078, p. 160, fig. 1*).—A disease of peaches due to *Helminthosporium rhabdiferum* is briefly described. This fungus, which causes a black moldy appearance of the ripened fruit, was first observed and described by Berkeley in 1864, but it appears not to have been recognized since that time. Although the fungus is rare, from the nature of its attack it would probably prove a decided pest if abundant.

The writer recommends the picking and burning of diseased fruits and spraying the trees with dilute Bordeaux mixture where the disease is present.

Diseases of strawberries (*Österr. Gart. Ztg., 2 (1907), No. 9, pp. 317-320*).—A summary is given of fungus and insect injuries to the strawberry. For the prevention of the various root diseases, the author recommends the sterilization of the soil where the plants are to be set with a weak solution of formaldehyde. To combat the attacks of Ramularia, Phyllosticta, and Ascochyta on the leaves the use of a 1 per cent Bordeaux mixture is advised. For the false or downy mildew spraying with Bordeaux mixture or ammoniacal copper carbonate is considered advantageous. For the prevention of powdery mildew, sulphur should be dusted over the plants or they should be sprayed with a fresh solution of potassium sulphid.

Studies on the development of Glœosporium ribis, the means of infection, and the methods for combating it, R. EWERT (*Ztschr. Pflanzenkrank., 17 (1907), No. 3, pp. 158-169, pls. 2*).—A description is given of the development of *G. ribis*, or *Pseudopeziza ribis*, together with the results of experiments on its means of infection and methods for preventing its attack upon currants.

The conidia were found to retain their viability over winter, and, it is believed, probably their power to infect the host plant also. The author thinks it doubtful whether the mycelium is perennial. Artificial inoculations show some natural resistance by the host toward the fungus. The disease is said to be limited by the age of the plants, as even with the most susceptible sorts it was impossible to infect either the leaves or stems until they had attained a certain growth and age. The time of natural infection is during May, and spraying with fungicides containing copper should be made early in that month.

Bordeaux mixture, S. Pickering (*Gard. Chron., 3. ser., 42 (1907), No. 1078, p. 150*).—In an editorial note an account is given of investigations on the chemistry of Bordeaux mixture.

It is stated that the claim that Bordeaux mixture consists principally of copper hydroxid is not based upon fact, since it consists of 5 complex substances formed by the action of lime on copper sulphate, the particular one depending on the proportions used. In making Bordeaux according to the ordinary formula, where the weight of lime used is from 4 to 6 parts to every 6 parts of crystallized copper sulphate, the substance formed is said to be a double basic sulphate of copper and calcium. However, where the lime is reduced to the lowest proportions consistent with the precipitation of the whole of the copper, the substance formed is essentially a basic sulphate of copper. In the former case when the mixture is exposed to the air the basic calcium sulphate present will be attacked by carbon dioxid, and until the calcium sulphate has all been converted into carbonate, the basic copper sulphate will remain practically intact. Where the basic sulphate is present there will be no period in which the fungicidal action is suspended, as there is no basic calcium sulphate present. This is held to be a decided advantage, as with the latter compound for equal weights of copper taken, two and one-half times as much copper sulphate would be liberated as with the double basic compounds.

For the preparation of the basic sulphate of copper, the author recommends the use of limewater in the proportion of 107 pints of limewater to each pound of copper sulphate. Bordeaux mixture made by this method is said to be more efficient and cheaper than that made by the ordinary formula. It is claimed that in all cases Bordeaux mixture should be tested in order to prevent the scorching due to an excess of copper sulphate.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Game commissions and wardens; their appointment, powers, and duties, R. W. Williams, Jr. (*U. S. Dept. Agr., Biol. Survey Bul. 28, pp. 285, pls. 8*).—This bulletin contains a general account of the office and duties of wardens, a condensed summary of the provisions of game laws relating to enforcement and the full text of such laws. The subject-matter is restricted to State laws. The topics are elaborately discussed and the matter is arranged for ready reference.

Game laws for 1907, T. S. Palmer, H. Oldys, and C. E. Brewster (*U. S. Dept. Agr., Farmers' Bul. 308, pp. 52, figs. 4*).—The essential new features of game laws passed in 1907 are given. The close seasons for different kinds of game in the various States are shown in a tabular form. The license system for hunting and shipping game is also discussed.

Our feathered immigrants, J. Drummond (*New Zeal. Dept. Agr., Divs. Biol. and Hort. Bul. 16, pp. VII + 49, pls. 8*).—A circular letter of inquiry was sent to the correspondents of the department regarding the economic relations of introduced birds, a list of which was supplied. Considerable evidence was thus collected as to the injuriousness of English sparrow, skylark, blackbird, song thrush, greenfinch, etc. On the other hand, good reports were received regarding lapwing, hedge sparrow, starling, etc.

It is evident from the New Zealand experience that no bird should be introduced in a country without a previous careful study of its habits. The author presents in a tabular form notes on the relative abundance of various native and introduced birds.

The introduction of top minnows into the Hawaiian Islands, D. L. Van Dine (*Hawaii Sta. Press Bul. 20, pp. 10, figs. 3*).—In 1904, top minnows belonging to the species *Gambusia affinis*, *Fundulus grandis*, and *Mollienesia latipinna* were collected in Texas by A. Seale, taken to Hawaii and liberated in ponds. About 75 of each species were introduced. They have multiplied to hundreds of thousands and have been planted in the waters of 5 islands. They thrive best in shallow water at a temperature of 76 to 82° F. The top minnows effectively rid the waters of mosquito larvæ and promise to be of great help in the problem of eradicating mosquitoes.

Report of the entomologist, D. L. Van Dine (*Hawaii Sta. Rpt. 1906, pp. 18–32*).—Considerable attention has been given to the encouragement of the silk industry in Hawaii. In cooperation with the Bureau of Entomology of this Department eggs of the Oro race of silkworms and other races have been imported and tested. The cocoons obtained in this experiment yielded a satisfactory amount of silk upon reeling, but lost too much in weight upon boiling out.

Neither European nor American foul brood of bees exists in Hawaii, and some attention is therefore being given to the encouragement of beekeeping. For this purpose an attempt is being made to introduce more desirable races and crosses of bees than the Italian bees which are already present in the islands.

A report is given on the successful introduction of fish for the destruction of mosquito larvæ. (See above.) The list of injurious insects of Hawaii is continued, and a list is given of the accessions to the entomological library relating to Hawaiian entomology.

Report of the entomologist, C. O. Houghton (*Delaware Sta. Rpts. 1904–1906, pp. 77–107*).—In controlling the apple-leaf miner fall plowing, spraying in June with a 10 per cent kerosene emulsion, and destruction of the leaves in the fall are recommended. Little benefit was noted from the use of sticky bands in capturing plum curculio.

Experiments in greenhouse fumigation indicate that white flies and plant lice may be readily controlled at very little expense. Fumigation with hydrocyanic-acid gas should be done at intervals of 4 to 6 weeks.

As a remedy for mosquito larvæ, crude petroleum proved better than kerosene, but a proprietary oil preparation was even more efficient. A list of the Coleoptera of Delaware is given together with notes on cabbage plutella, cabbage butterfly, rose leaf beetle, and oyster-shell bark-louse.

Injurious insects and other animals observed in Ireland during the year 1906, G. H. Carpenter (*Econ. Proc. Roy. Dublin Soc., 1 (1907), No. 11, XIX, pp. 421–452, pls. 6, figs. 11*).—Sheep were freed from *Trichodectes sphærocephalus* by dipping twice in arsenic and whale-oil soap. Barley was attacked by *Elachyptera cornuta*. Cabbage was damaged by diamond-back moth, root-gall weevil, and *Psylliodes chrysocephala*.

Notes are also given on *Silpha opaca*, cutworms, winter moth, plum aphis, oyster-shell scale, black-currant mite, pine weevil, *Phyllodecta vulgatissima*, etc.

Work of the zoological and entomological laboratory, J. Vosseler (*Ber. Land u. Forstw. Deutsch-Ostafrika, 3 (1907), No. 3, pp. 108–119*).—Among injurious locusts *Zonocerus elegans* caused most damage. Sisal was attacked by a species of Achræa. Mention is made of the most important insect pests of cotton, cocoanut, rubber plants, coffee, castor oil plant, fruit trees, cinchona, garden vegetables, etc.

Greenhouse pests of Maryland, A. B. Gahan (*Maryland Sta. Bul. 119, pp. 36, figs. 8*).—The author aims to give an account of the appearance, habits, and life history of all the important animal pests of greenhouses in Maryland. These include mealy bugs, various scale insects, plant lice, white fly, red spider, thrips, wireworms, snow bugs, and slugs.

The proposed remedies include syringing with water, fumigation, dusting, spraying, and dipping. Directions are given for the preparation and application of insecticides.

The periodical cicada, C. L. Marlatt (*U. S. Dept. Agr., Bur. Ent. Bul. 71, pp. 181, pls. 6, figs. 68*).—This is a thorough revision of Bulletin 14 of the Division of Entomology (E. S. R., 10, p. 1071). Additional data are given on the habits of the periodical cicada. The broods of the insect have been so renumbered as to indicate their relationship in time and geographical distribution. An extensive bibliography of the subject is presented (pages 154–169).

Locust destruction (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 6, pp. 609–617*).—An intercolonial conference was held by representatives of the British colonies of South Africa. It appears desirable that each colony should seriously attack the locust problem. The best remedy is a sweetened solution of arsenite of soda. Treatment should be applied to the locusts in their nymphal stage.

The spring grain-aphis or so-called "green bug," F. M. Webster (*U. S. Dept. Agr., Bur. Ent. Circ. 93, pp. 18, figs. 7*).—The third serious outbreak of *Toxoptera graminum* in the United States occurred during the last spring. The pest is distributed east of longitude 105° and south of latitude 41°, and breeds from sea level to an altitude of 5,000 ft. During warm weather a generation is passed in 8 days. In ordinary seasons the natural enemies of this pest keep it in check. In addition to cereals the insect has several alternative food plants.

Tobacco dust had no effect on the aphis, but kerosene emulsion gave good results. Parasites, particularly *Lysiphlebus tritici*, overcome the aphis unaided if weather conditions are favorable, but colonization of the parasites is of no avail. Much good may result from plowing and harrowing infested ground, running a surface fire, or from the use of kerosene emulsion. Rotation of crops, better cultural methods, and irrigation have also proved of considerable importance in the control of the aphis.

The chinch bug, F. M. Webster (*U. S. Dept. Agr., Bur. Ent. Bul. 69, pp. 95, figs. 19*).—This is a revised and enlarged edition of Bulletin 15 of the Division of Entomology (E. S. R., 10, p. 1069). Particular attention has been given to a revision of the remedies for controlling the chinch bug and to the study of its origin and distribution.

Cotton insects, L. de la Barreda (*Bol. Com. Par. Agr., 4 (1907), No. 2, pp. 107–215, pls. 24, map 1*).—A series of questions was sent to various planters in Mexico regarding the prevalence, injurious attacks, and means commonly adopted for combating the cotton-boll weevil. The replies received are summarized by the author. Considerable attention is given to the work of the Bureau of Entomology of this Department in the control of the boll weevil.

The sugar-cane leaf-roller, with an account of allied species and natural enemies, O. H. Swezey (*Hawaiian Sugar Planters' Sta., Div. Ent. Bul. 5, pp. 61, pls. 6, figs. 3*).—A technical description is given of *Omiodes accepta* and of various other species of that genus. The life history and food plants of each species are discussed. A table is given for the identification of the species.

Omiodes may be destroyed by spraying young cane plants with arsenicals or by hand picking. The life history and economic importance of various parasites of Omiodes are discussed.

Papers on deciduous fruit insects and insecticides. The pear thrips, D. MOULTON (*U. S. Dept. Agr., Bur. Ent. Bul. 68, pt. 1, pp. 16, pls. 2, figs. 8*).—*Euthrips pyri* has caused serious damage to deciduous fruit trees in the Santa Clara Valley and San Francisco Bay counties for the past 2 or 3 years. It attacks the buds of peach, apricot, pear, prune, cherry, apple, and other trees, causing perhaps most injury to pears. The adult thrips appear in February and March and disappear about the middle of May. From that time until the next spring the insect lives in the soil at a depth of about 4 or 5 in.

The eggs are deposited in the blossoms, stems, leaf petioles, and leaf veins, and as soon as the young hatch they feed upon the tender parts of the leaves. A technical description is given of the insect in its different stages.

In combating this pest contact insecticides have been found effective upon the exposed thrips, but soon after spraying the trees appear to be reinfested from thrips which were not touched by the spray and from other sources. It is believed that a thorough cultivation of the soil will destroy a considerable percentage of the larvæ and nymphs. The thrips are preyed upon by a few predaceous enemies and are also attacked by a parasitic fungus belonging to the genus Cladosporium.

Papers on deciduous fruit insects and insecticides. The spring cankerworm, A. L. QUAINTANCE (*U. S. Dept. Agr., Bur. Ent. Bul. 68, pt. 2, pp. 17–22, pls. 2*).—The spring cankerworm causes the almost total defoliation of orchards in certain localities. For controlling this pest it is recommended on the basis of demonstration experiments that infested orchards be sprayed with Paris green (1 lb. in 100 gal. of water) or arsenate of lead (6 to 10 lbs. in 100 gal. of water). If the Paris green is not used in Bordeaux mixture, 5 or 6 lbs. of lime should be added for each 100 gal. of water. Moreover the soil about the trees should be thoroughly cultivated in summer, and some benefit may be expected from the use of sticky bands on the trunks of the trees.

Papers on deciduous fruit insects and insecticides. The trumpet leaf-miner of the apple, A. L. QUAINTANCE (*U. S. Dept. Agr., Bur. Ent. Bul. 68, pt. 3, pp. 23–30, pl. 1, fig. 1*).—*Tischeria malifoliella* is described in all its stages, and notes are given on its history and distribution. The insect has been reported on apple, haw, crab, raspberry, etc. The author did not observe it on blackberry.

There are two broods annually. The insect is distributed from South Carolina to Canada. A number of parasites attack the pest. Badly infested leaves fall prematurely. The insect may be partly controlled by plowing the ground in spring and by spraying with a 12–15 per cent kerosene emulsion.

Papers on deciduous fruit insects and insecticides. The lesser peach borer, A. A. GIRAULT (*U. S. Dept. Agr., Bur. Ent. Bul. 68, pt. 4, pp. 31–48, pl. 1, fig. 1*).—This insect, although described in 1868, has not been considered an important pest until recent years. It occurs on both wild and cultivated plums and cherries, Juneberry, beach plum, chestnut, and peach, showing a preference for the peach. The insect is distributed from Canada to Florida and to the Pacific Coast, but appears to be most injurious to peaches in New Jersey, New York, Virginia, Ohio, Georgia, and Maryland.

The lesser peach borer passes the winter in the larval condition under the bark. The moths appear in March and April, deposit their eggs soon afterwards, and the young penetrate through the crevices of the bark. There are 2 generations annually. The insect is carefully described in all its stages. Apparently the adults do not live longer than 1 week. The life cycle of the summer generation is about 4½ months and of the winter generation 7½ months.

A number of natural enemies, mostly Hymenoptera, have been observed. The best means of controlling the insect consist in good cultivation and care of the peach orchards and in cutting the larvæ out of their burrows.

The Howard scale, E. P. Taylor (*Colorado Sta. Bul. 120, pp. 19, figs. 4*).—*Aspidiotus howardi* was discovered on the fruit and bark of the prune and wild plum in 1894. It now occurs in many fruit orchards in Colorado, and appears to be a native of the State. It is less destructive than the San José scale, but it attacks pear, plums, and prunes.

A number of natural enemies have been observed which help to keep the pest in check, but the main reliance must be placed on the use of lime-sulphur wash in late spring.

Codling moth, C. Börner (*Mitt. Bl. K. Preuss. Verwalt. Landw., Domänen u. Forsten, 3 (1907), No. 4, Anz. Beilage, pp. 104–107, figs. 6*).—The appearance and life history of the codling moth are briefly outlined. The pest is to be combated by the use of bands about infested trees, destruction of windfall apples, and spraying with Bordeaux mixture containing an arsenical.

Mites and lice on poultry, N. Banks (*U. S. Dept. Agr., Bur. Ent. Circ. 92, pp. 8, figs. 6*).—A description is given of the common chicken mite. This pest may best be controlled by repeated spraying of hen houses with kerosene emulsion. Other remedies, such as lime and sulphur or whitewash and carbolic acid, have given fairly good results. The mite which causes scaly legs may be controlled by the use of warm soap suds and sulphur ointment. Brief notes are also given on *Cnemidocoptes gallinæ*, *Rivoltasia bifurcata*, and *Argas miniatus*.

In controlling chicken lice mixtures of carbolic acid and lime, or kerosene, sulphur, and lime, or kerosene and naphthaline may be used. Notes are also given on *Menopon biseriatum*. If eggs are hatched in incubators and chickens cared for in brooders, poultry may be raised without becoming infested with lice and mites.

Dipping nursery stock in insecticides, C. P. Close (*Delaware Sta. Rpts. 1904–1906, pp. 48–69*).—Nursery stock of apple, pear, plum, and peach trees was dipped in kerosene limoid emulsion, pure kerosene, crude petroleum, lime-sulphur-salt wash, and a number of proprietary insecticides. The stock was dipped and planted from April 25 to May 4. As a result of these tests it appears undesirable to dip the roots of nursery stock. As a dip for the tops kerosene, crude petroleum, and a 25 per cent kerosene limoid emulsion are recommended for apples and pears, and for plums crude petroleum and kerosene limoid 30 to 50 per cent. The results obtained with peaches are not considered satisfactory.

Young strawberry plants of several varieties were dipped in various strengths of kerosene limoid emulsion, whale-oil soap-kerosene emulsion, whale-oil soap alone, and tobacco with or without whale-oil soap. The mixtures containing kerosene injured the plants quite seriously, while those containing tobacco or whale-oil soap were relatively harmless.

Fumigation for the destruction of insects, A. I. Kendall (*Proc. Ann. Conf. Sanit. Off. N. Y., 6 (1906), pp. 191–196*).—Attention is called to the work which has been done in the destruction of mosquitoes and household insects in Cuba, Panama, and elsewhere. In this work sulphur, pyrethrum, camphor and carbolic acid, hydrocyanic-acid gas, etc. have been used.

Lead arsenate and Paris green, J. P. Street and W. E. Britton (*Connecticut State Sta. Bul. 157, pp. 13*).—The content of arsenic oxid in samples of lead arsenic varied from 11.29 to 21.91 per cent, and the lead oxid from 25.59 to

44.05 per cent. The percentage of soluble arsenic was low in all samples. The impurities were partly nitrates but were not determined more accurately. At the usual market prices lead arsenate is cheaper than Paris green.

In samples of Paris green the amount of arsenious oxid ranged from 56.2 to 61.19 per cent, and cupric oxid from 25.56 to 30.27 per cent. Most of the samples contained too much soluble arsenic.

Directions were given for the preparation and use of lead arsenate and Paris green.

Pyrethrum powder, A. L. Herrera (*Com. Par. Agr. [Mexico], Circ. 61, pp. 24, pls. 6*).—A botanical discussion is given on the plants from which pyrethrum powder is made. The uses of this powder in the control of various insect pests are also mentioned. The methods of preparation of pyrethrum powder are described and notes are given on its chemical composition.

Spray materials, C. L. Penny (*Delaware Sta. Rpts. 1904–1906 pp. 34, 35*).—It was observed that carbon dioxid decomposes lime-sulphur-salt wash setting free sulphureted hydrogen and sulphur. It is doubtful, however, whether in case this gas is compressed in a power-spraying apparatus a sufficient length of time will be given for it to act disastrously upon the composition of the insecticide.

Proceedings of the nineteenth annual meeting of the Association of Economic Entomologists (*U. S. Dept. Agr., Bur. Ent. Bul. 67, pp. 145, pl. 1, figs. 7*).—The nineteenth annual meeting of the Association of Economic Entomologists was held at Columbia University, New York City, December 28, 29, 1906. At this meeting a number of papers on entomological topics were presented, together with reports of committees on nomenclature, cooperative testing of insecticides, and National control of introduced insect pests. As at previous meetings of the association, several short papers were presented dealing with the biological and economic aspects of the more important insect pests of the year. Such accounts were presented for Minnesota by F. L. Washburn, for New Jersey by J. B. Smith, for Maryland by A. B. Gahan and G. P. Weldon, for New York by E. P. Felt, for Georgia by R. I. Smith, for the Philippines by C. S. Banks, and for Central Alberta by P. B. Gregson.

The Occurrence of the Gipsy Moth in Connecticut was discussed by W. E. Britton (pp. 22–26). The work of eradication has progressed satisfactorily and it is now difficult to find any indication of the gipsy moth. W. J. Schoene reported the willow borer as very destructive to nursery plantations of poplar and willow (pp. 27, 28). Some benefit was derived from the use of arsenical sprays. Aphis eggs, particularly those of species which occur on apples, are nearly all destroyed by spraying with sulphur wash or crude oil, according to experiments by H. E. Hodgkiss (pp. 29, 30). Accounts were also presented on the manner of birth of the woolly aphis, by W. E. Rumsey (pp. 31–33); of injury by the pear blister mite to apple leaves, by P. J. Parrott (pp. 43–46); and of the natural enemies of the cottony maple scale, by E. L. Dickerson (pp. 48–52).

The different methods used in estimating the benefit of spraying for codling moth were discussed by A. F. Burgess (pp. 53–55). E. D. Ball presented a paper on The Control of the Codling Moth in the Arid Regions (pp. 55–75). The codling moth in Utah has been shown to be definitely two-brooded. It is so abundant as to require 5 to 8 insecticide applications. More than two-thirds of the first brood and nearly two-thirds of the second brood of larvæ enter the calyx and about 98 per cent of these larvæ were destroyed by two early applications.

Suggestions regarding suitable subjects for entomological research under the Adams Act were made by E. D. Sanderson (pp. 77–84). B. H. Walden reported a new sawfly (***Pamphilius persicum***) as injurious to peach leaves (pp. 85, 86).

The practical work done in Colorado in combating the Howard scale was discussed by E. P. Taylor (pp. 87–93). Good results were obtained from the use of lime-sulphur mixture and other insecticides. F. M. Webster discussed the value of parasites in the control of the insect enemies of cereals and forage crops (pp. 94–100). In this paper particular attention was given to wheat midge, Hessian fly, jointworms, and army worm.

A paper on the insect enemies of tobacco in Florida was discussed by W. A. Hooker (pp. 106–111), special mention being made of bud worms, tobacco worms, tobacco flea-beetle, grasshoppers, tobacco leaf-miner, cutworms, and leaf hoppers. E. D. Sanderson presented suggestions regarding the construction of a spray nozzle which will give definite proportions of a mechanical mixture of oil and water (pp. 112–116).

The other papers presented at the meetings included one on *Gastrophilus nasalis* and *Ceratopogon eriophorus* and insects in relation to leprosy, by C. F. Baker (pp. 117–119). On the Eradication of the Black-Currant Gall-Mite, by W. E. Collinge (pp. 119–123; and the destruction of mosquitoes in houses by means of chrysanthemum, by A. L. Herrera (pp. 123, 124).

Report of the meeting of inspectors of apiaries (San Antonio, Tex., November 12,) 1906 (*U. S. Dept. Agr., Bur. Ent. Bul. 70, pp. 79, pl. 1*).—At a meeting of inspectors of apiaries in San Antonio, Texas, November 12, 1906, a number of papers were read, which have been collected in the present bulletin.

The Bacteriology of Bee Diseases was discussed by G. F. White (pp. 10–18). The speaker recognized 3 infectious bee diseases—European foul brood, American foul brood, and pickle brood.

E. F. Phillips referred to The Present Status of the Investigation of Bee Diseases. A historical account of the subject was given and detailed notes were presented on the growth and behavior of *Bacillus alvei*, *B. A.*, and *B. larvæ*.

Apiary inspection in New York was considered by C. Stewart. An inspector must be a practical bee raiser. No bees are strictly immune to disease, but vigorous Italians are nearly so.

F. A. Parker spoke of American Foul Brood on the Pacific Coast. In California the disease behaves somewhat differently than in other parts of the country. Some bee raisers have as many as 4,000 swarms. The disease spreads rapidly in many cases. Much careful attention is required on the part of the inspectors to prevent disaster.

N. E. France outlined the history of bee inspection in Wisconsin, referring particularly to the difficulties met by the inspector in carrying out the State law.

Practical bee keeping, R. Benton (*Montana Sta. Bul. 67, pp. 75, pls. 4, figs. 15*).—A summary is given of information important to the beginner and small apiarist. The bulletin is based on available data and experiments in Montana. The subject-matter includes the structure, habits, and varieties of the honey bee, and a discussion of honey plants, beehives, handling of bees, starting an apiary, wintering bees, queen rearing, control of swarming, production of honey, and diseases of bees.

Bee culture, I. Hopkins (*New Zeal. Dept. Agr., Divs. Biol. and Hort. Bul. 18, pp. 34, figs. 24*).—Practical directions are given regarding the care and management of bees, including the location of the apiary, hives, and other bee apparatus, honey plants, etc. A special section of the bulletin is devoted to a discussion of the relation of bees to flowers and fruit growing.

The cause of American foul brood, G. F. White (*U. S. Dept. Agr., Bur. Ent. Circ. 94, pp. 4*).—The author had previously announced the occurrence of *Bacillus larvæ* in American foul brood. In experiments reported in this circular the disease was transmitted to healthy colonies of bees by material from diseased larvæ and by pure cultures of *B. larvæ*. A new culture medium containing the sterile filtrate of healthy bee larvæ has been prepared for use in the cultivation of *B. larvæ*. It is held that the structures described by A. Maassen as *Spirochæta apis* are nothing but the giant whips of *B. larvæ*.

Influence of high temperatures on the eggs of silkworms, E. QUAJAT (*Agr. Mod., 13* (*1907*), *No. 36, pp. 507–509*).—Temporary exposure of the eggs of various races of silkworms to temperatures up to 45° C. had no apparent effect upon the development of the larva or the quality of the silk produced.

FOODS—HUMAN NUTRITION.

The economic seaweeds of Hawaii and their food value, MINNIE REED (*Hawaii Sta. Rpt. 1906, pp. 61–88, pls. 4*).—Marine algæ are important in the diet of native Hawaiians, as they are in China and Japan. Some varieties are cultivated in addition to the abundant supply found native on the coast. The methods of gathering algæ, which are known in Hawaii as limu, the native methods of preparing and serving them, methods of preservation, native methods of cultivation, and other similar questions are discussed and analyses of 3 species made by R. A. Duncan are reported.

As regards composition, the marine algæ somewhat resemble green vegetables and according to the data summarized are especially useful for supplying bulk to the ration, while the algæ gelatins are also important in counteracting a tendency to constipation. "Mineral matters are needed for the formation of bones, teeth, and other tissues, and to fulfill other physiological functions. The algæ are rich in phosphates, chlorids, bromids, iodids, etc., and it seems probable that the mineral matter which they supply must be of importance to the body."

The native Hawaiians use these edible seaweeds to a great extent as salads and relishes. In the author's opinion, they are more palatable when used in other ways. As shown by culinary tests "many of the seaweeds when cooked in soups, gravies, or with meats, or made into jellies, are entirely free from . . . [any] disagreeable or peculiar flavor. If cooked too long, or too large a quantity is used in the soups or jellies, the flavor is apt to be strong, but if used in smaller quantities it is very delicate and pleasant. The writer has carefully tested a number of species, cooking them in a variety of combinations. They seem to be equally palatable when used either fresh or dried. The bleached seaweeds of course make the best appearing jelly and blancmange, and look best in the soups and stews."

Satisfactory results were obtained when mucilage was made from seaweeds and also with seaweed gelatin used as culture media in laboratory work. "If the tons of algæ wasting on our shores could be utilized for gelatin, glue, farina, etc., it would . . . add to the general wealth and prosperity of these islands and to the United States.

"Further experiments and analyses should be made by the Government to test the nutritive value of our algæ and to find the best methods of securing the greatest amount of gelatin from each variety. Enough has already been done to suggest the future value of our economic algæ if properly utilized."

A list of edible algæ of the Hawaiian Islands is appended to the report.

The chemistry of strength of wheat flour, T. B. WOOD (*Jour. Agr. Sci., 2* (*1907*), *No. 2, pp. 139–160, figs. 2*).—As the chemical composition of the gliadin and glutenin of strong and weak flours was found to be identical in all the samples examined, it seemed probable that the difference between strong and weak flours might lie in the physical rather than the chemical properties of their gluten.

"Since it is well known that the physical properties of proteids are profoundly affected by small quantities of acids, alkalis, and salts, the amounts of these substances in strong and weak flours were determined. In the few cases examined, it was found that the strength was associated with a high ratio of proteid to salts and weakness with a low ratio. It is suggested that the variation of this ratio may be the explanation of the different physical behavior of the gluten of strong and weak flours, and that this is the factor which determines that component of strength which governs the shape of the loaf and its power of retaining gas. This point is receiving further investigation.

"The factor which primarily determines the size of a loaf which a flour can make is quite distinct. The size of the loaf is shown to depend in the first instance on the amount of sugar contained in the flour together with that formed in the dough by diastatic action. It is proposed to measure this by incubating the flour with yeast and water, and collecting the carbon dioxid evolved during 24 hours. Particular attention should be paid to the rate of gas evolution in the later stages of the fermentation, as this is shown to be more directly connected with the size of the loaf. . . .

"The largeness of the loaf depends chiefly on the capacity of the flour to give off gas when fermented with yeast, especially in the later stages of dough fermentation, and the suggestion is made that shapeliness, and probably gas retention, are dependent on the physical properties of the gluten as modified by the presence of varying proportions of salts."

A comparison of various methods of estimating the baking qualities of flour, R. W. THATCHER (*Jour. Amer. Chem. Soc., 29 (1907), No. 6, pp. 910–921*).—From the results of the comparative tests reported, the author concludes that "no single test which was tried is capable of giving conclusive evidence as to the baking quality of flour. Any of the processes which have yet been suggested for testing flour must be supplemented by a baking test if final and accurate conclusions are to be reached.

"The baker's sponge tests appear to afford little evidence of value except in the case of low-gluten flours. Inasmuch as these tests require nearly as much actual work and fully as much care and attention as the complete baking tests, it appears that they may well be abandoned in favor of the latter."

Portuguese studies of flour, F. DA SILVA (*Rev. Chim. Pura e Appl., 1 (1905), pp. 262–265; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 9, p. 582*).—The analyses of flour reported were made to secure data for judging of the quality of Portuguese flour and its agreement with the legal standard.

Zwieback preparations, K. FISCHER and O. GRUENERT (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 11, pp. 692–697*).—A number of compounds recommended by manufacturers as additions to zwieback cakes and other bakers' goods were examined and found to contain small quantities of soap. The authors state that in Holland and some other localities it has been a common practice to add a small amount of soap to such goods with the idea of lessening the amount of egg required to make goods light, etc. The data reported are discussed with reference to the detection of soap in bakers' goods.

Phosphoric acid in barley, W. WINDISCH (*Jahrb. Vers. u. Lehranst. Brauerei Berlin, 9 (1906), p. 36; abs. in Chem. Zentbl., 78 (1907), I, No. 19, p. 1439*).—According to the author's investigations, no phosphorus occurs in barley in inorganic form, although such phosphorus compounds are formed during sprouting and malting. If barley contains any mineral phosphoric acid, it is either unripe or has sprouted or been changed in character in some similar way. The change of phosphoric acid from organic to inorganic form is due to the action of an enzym. The nature of the organic phosphorus compound is not yet known, but the author intends to continue his investigations.

Ripening of oranges, W. D. Bigelow and H. C. Gore (*Jour. Amer. Chem. Soc., 29 (1907), No. 5, pp. 767–775, figs. 2*).—Studies of the proportion of pulp, seeds, and skin in oranges in different stages of growth, and the composition of the pulp, showed that the increase of pulp and skin during growth was much more rapid with the pulp than with the skin. "In regard to the changes in the pulp, the acid of the fruit and the cell-wall tissue, or marc, are formed early in the life history of the fruit and remain nearly unchanged in quantity during the subsequent development. The sugars increase gradually during the growth of the orange, sucrose and reducing sugar existing in approximately equal quantity.

"Storage of the fruit at room temperatures at all stages of its development results in slight loss of acid and of total sugar, a marked increase of reducing sugar, and a corresponding decrease of sucrose. The loss of acid and sugar noted above is to be explained as in the case of apples by the consumption of these substances as a result of the respiration of the fruit. The weight of marc remains practically constant, and the weight of acid appears to decrease slightly on storage during the various stages of the development of the orange."

Some tropical starches, E. Hess (*Ztschr. Allg. Österr. Apoth. Ver., 44 (1906), p. 25; Apoth. Ztg., 21 (1906), p. 57; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 9, p. 586*).—The starches studied microscopically were obtained from *Cariota urens*, dried bread fruit, *Alocasia macrorhiza*, *Inocarpus edulis*, and Conophallus.

Iron in vegetable and animal tissues, A. Mouneyrat (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 19, pp. 1067, 1068*).—The iron content of bread of different sorts, fruit, cows' milk, goats' milk, cereals, vegetables, egg yolk, and table salt is reported, the determinations being made by a method which the author considers very exact.

The amount of lecithin in egg yolk, A. Manasse (*Biochem. Ztschr., 1 (1906), No. 3, pp. 246–252*).—Moist yolk of hens' eggs, as shown by the investigations reported, contains on an average 9.41 per cent lecithin.

Changes in alimentary pastes containing eggs and their effect upon the determination of the egg content, A. Beythien and P. Atenstädt (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 11, pp. 681–692*).—When alimentary pastes containing eggs were stored no change was noted in the total phosphoric acid. Lecithin-phosphoric acid diminished somewhat when the amount present was high. The alcohol-soluble phosphoric acid remained practically unchanged when the egg pastes were kept for 8 to 16 months. The fat content was not found to be dependent upon age, but the iodin number of the fat showed changes.

The edibility of animal spleens, E. T. Williams (*Amer. Med., 11 (1906), No. 6, p. 215*).—On the basis of personal experience, the author considers spleens of domestic animals palatable food. He points out that owing to their soft texture and the great number of blood corpuscles spleens spoil very readily.

Experimental greening of oysters, C. Sauvageau (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 17, pp. 919–921*).—As shown by the author's experiments oysters become green in color after feeding upon a diatom (*Navicula ostrearia*). The coloration is due not simply to the presence of diatoms on the colored portion, but to the fixation in the tissues of coloring matter derived from them.

Beverages, A. L. Girard (*Les Boissons. Paris, 1906, pp. 96, figs. 26*).—The manufacture, characteristics, and quality of beverages are discussed, these including wine, beer, vinegar, distilled liquors and similar alcoholic beverages, fermented milk products, liqueurs, and similar articles.

Further notes on the sodium content of grape wine, O. Krug (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 9, pp. 544–547*).—The reported data regarding the mineral constituents of wine have to do with the ratio of sodium to chlorin under the requirements of the German pure-food law, and particularly the influence of nitrate of soda on abnormal sodium content.

Further investigations on stored raspberry juice, R. Kržižan (*Ztschr. Offentl. Chem., 13 (1907), No. 10, pp. 181–184*).—From the analytical data reported and discussed the author concludes that provided fermentation has ceased there is no noticeable change where raspberry juice is stored for months without added preservative. Sterilizing at 80° is sufficient for preservation provided the bottles are sterile. The amount of acetic acid formed from the citric acid and alcohol present is certainly very small.

From the changes in color and aroma it was found that stored raspberry juice can entirely lose its color without loss of aroma, so that it is evident that these factors are not dependent one upon the other.

Coffee and estimation of its value, L. E. Sayre (*Trans. Kans. Acad. Sci., 20 (1906), pt. 2, pp. 37–43*).—The author calls attention to the fact that the caffein content of coffee varies considerably according to the locality in which it is grown, recent analyses made in his laboratory reporting a range of 0.08 to 1.97 per cent of this constituent. He believes that this fact is not properly appreciated in the selection of coffee. Studies of the volatile aromatic constituents of roasted coffee have been made, but recorded data are not regarded as sufficient for general deductions. Methods of coffee analysis are briefly discussed.

Judging paprika, R. Kržižan (*Ztschr. Offentl. Chem., 13 (1907), No. 9, pp. 161–165*).—Analyses of extracted and unextracted paprika are reported which were undertaken to secure data for judging the quality of this condiment. The author finds that the coloring matter present and the constituent which imparts the sharp taste may be readily extracted with alcohol, but that it is difficult to remove the paprika aroma by this means.

The use of binding material in sausage making, A. Behre (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 9, pp. 525–533*).—A summary and discussion of data on the use of so-called binding material in sausage making, with special reference to the relation of this topic to pure food laws.

The effect of different preservatives on chopped meat, A. Kickton (*Ztschr. Untersuch. Nahr. u. Genussmtl., 13 (1907), No. 9, pp. 534–542*).—The effect of different preservatives on the keeping quality and color of chopped meat was studied. The recorded data showed that adding preservatives to chopped meat which was beginning to spoil removed the odor, which would, of course, facilitate the use of inferior material. The author believes that chopped meat should be made from fresh material and that no preservative should be added without the knowledge of the consumer.

Corn oil: Its possible use as an adulterant in lard and its detection, W. McPherson and W. A. Ruth (*Jour. Amer. Chem. Soc., 29 (1907), No. 6, pp. 921–926*).—Noted from another publication (E. S. R., 18, p. 1147).

German food laws. I, Handbook of food laws; II, Official methods for chemists, G. Lebbin and G. Baum (*Deutsches Nahrungsmittelrecht. Vols. 1, Handbuch des Nahrungsmittelrechts, XI+555; 2, Amtliche Untersuchungsmethoden für Chemischer, pp. 224, figs. 7. Berlin, 1907*).—The first volume, which is by both authors, contains a summary of German legal enactments regarding food adulteration, and the second, which is by Lebbin, the regulations for chemical examination of foods in connection with food adulteration.

Food inspection decisions, H. W. WILEY, F. L. DUNLAP, and G. P. MCCABE (*U. S. Dept. Agr., Food Insp. Decisions 77, pp. 6; 78–79, pp. 4*).—The topics covered by these decisions are certificate and control of dyes permissible for use in coloring foods and foodstuffs, the use of labels after October 1, 1907, and the collection of samples.

A preliminary communication on the toxicity of some anilin dyestuffs, G. M. MEYER (*Jour. Amer. Chem. Soc., 29 (1907), No. 6, pp. 892–909*).—Several commercial organic dyestuffs (curcumin S, tartrazin, naphthol red S, carmoisin B, naphthol yellow S, gold orange and ponceau 2R) were studied as to their general effects on dogs when administered in varying amounts and for fairly long periods (2 weeks).

"None of these dyestuffs under the conditions above indicated exhibited any marked degree of toxicity. There was only one fatal result, which may have been due to influences independent of the action of the colorant.

"The dyestuffs were all excreted, in part unchanged, with the feces and to a slight extent in the urine. Their presence was demonstrated in the bile but they were not secreted in the milk (bitch).

"Peptic digestion experiments have shown that these dyes like many other substances inhibit peptolysis in vitro. The interference noted may have been due to the associated inorganic matter."

A study of metabolism in a healthy vegetarian, W. G. LITTLE and C. E. HARRIS (*Bio-Chem. Jour., 2 (1907), No. 5–6, pp. 230–239*).—The income and outgo of nitrogen and iron, the urea content of the urine, and other factors were recently determined in the case of a man who, the authors state, had been a vegetarian for about 20 years, with favorable results to his health. Some data are also recorded regarding specific gravity and composition of the urine of the same subject at an earlier period on the same kind of diet.

As shown by the menus quoted, milk and eggs were used as well as vegetable foods. For the 14 days covered by the more complete investigation the average protein consumption was about 50 gm. per day. Thirty per cent of the nitrogen eaten was excreted in the feces. The average intake of iron as estimated for 7 days was 8 mg. per day and the output in the feces 3 mg. The subject weighed 127 lbs. and this weight was fairly constant. The exercise taken was apparently moderate.

A comparison of the excretion of inorganic constituents in the urine of the vegetarian and a gouty subject who ate meat was made. "The difference in calcium output is the most interesting fact [observed] . . ., especially when it is remembered that the total amount of urine execreted by the gouty patient was more than double that of the vegetarian. The figures suggest that perverted calcium excretion may be a factor in the pathogeny of gout, and that in gout an excess of calcium is being excreted by the kidneys, which under normal conditions would be removed by intestinal excretion."

The effect of a meat diet on fertility and lactation, B. P. WATSON (*Proc. Roy. Soc. Edinb., 27 (1906–7), No. 1, pp. 6–10, pl. 1*).—From experiments with white rats the author concludes that a meat diet is prejudicial to the occurrence of pregnancy in rats, and that in rats fed on a meat diet the mammary development of nursing mothers is less than in rats fed on bread and milk.

The influence of an excessive meat diet on the osseous system, C. WATSON (*Proc. Roy. Soc. Edinb., 27 (1906–7), No. 1, pp. 2–5, pls. 4*).—The investigations reported, which were made with white rats, led the author to conclude that "the bones of animals fed on an excessive meat diet present an appearance of delayed and imperfect ossification, with increased vascularity, and an increase in the number of red blood corpuscles."

The effect of diet on endurance, I. FISHER (*Trans. Conn. Acad. Arts and Sci., 13 (1907), pp. 1–46*).—The investigations here reported in detail have been noted from a summary previously published (E. S. R., 19, p. 63).

The effect of muscular work on weight, composition, and water content of organs of the animal body, F. ROGOZINSKI (*Biochem. Ztschr., 1 (1906), No. 3, pp. 207–228*).—Dogs were used as the subjects of experiments undertaken to study the effects of muscular work. Work was performed with a dynamometer.

According to the author's summary, neither the physical properties nor the chemical composition of the blood were modified during the work periods. The recorded data indicate that the water content of the organs of the body is diminished by long-continued work. The lowered body weight during the work periods is an indication that this supposition is correct. An increase in the size of working muscles and the heart was not noted, except in one test.

Experiments on the exhalation of water vapor, H. GUILLEMARD and R. MOOG (*Compt. Rend. Soc. Biol.* [*Paris*], *62 (1907), No. 16, pp. 874–876*).—In experiments with small animals (guinea pigs) on the effect of variations in atmospheric pressure and temperature, it was found that conditions approximating those of high altitudes were not favorable to the exhalation of water vapor.

The part played by free nitrogen in animal metabolism, C. OPPENHEIMER (*Biochem. Ztschr., 1 (1906), No. 3, pp. 177–182*).—A preliminary account of investigations from which the conclusion was drawn that free nitrogen is inert as regards body metabolism.

The selective function of the stomach during digestion in the light of recent investigations, A. SCHEUNERT (*Ztschr. Physiol. Chem., 51 (1907), No. 6, pp. 519–544, figs. 3*).—From the data summarized and discussed the author concludes that the stomach does not exert a selective function in digestion. All the materials leave the stomach in the same way. The more rapid disappearance of digestible materials is due to the absorptive power of the stomach.

The point where proteid cleavage begins in the body in fasting and feeding, E. FREUND (*Ztschr. Expt. Path. u. Ther., 4 (1907), No. 1, pp. 1–56*).—The experiments reported led to the conclusion that protein is first changed in the intestine to a condition in which it is readily resorbed, and further, that under usual conditions the greater part of the energy-yielding protein cleavage takes place there which has been supposed to take place in the body cells. The occurrence of putrefaction products, fat bodies, and iron and calcium salts in the intestine and feces during fasting probably indicates that material derived from the blood and cells undergoes cleavage in the intestine.

The behavior of ovomucoid in the body, K. WILLANEN (*Biochem. Ztschr., 1 (1906), No. 1–2, pp. 108–128*).—From a study of ovomucoid, the author concludes that it has the characteristics of a gluco-proteid and that when taken into the stomach it is oxidized and so very probably can be counted as a food proteid. When eggs are eaten this substance is utilized as it occurs preformed in fresh eggs and is not changed by cooking. Experiments showed that the carbohydrate group could be separated from ovomucoid by digestion with pepsin and by putrefaction. On the other hand, neither digestion with trypsin nor autolysis induced cleavage of glucose amin.

Concerning creatinin formation, J. SEEMANN (*Ztschr. Biol., 49 (1907), No. 2, pp. 333–344*).—On the basis of experimental evidence the author believes that creatinin may be formed from protein by cleavage. The work of other investigators is discussed as well as the results of his own experiments.

New reasons for believing that free sugar occurs in the blood, E. PFLÜGER (*Arch. Physiol.* [*Pflüger*], *117 (1907), No. 3–4, pp. 217–222*).—A summary and discussion of recent investigations which have to do with the occurrence of free sugar in the blood. A polemical article.

International catalogue of scientific literature. Q—Physiology (*Internat. Cat. Sci. Lit., 5 (1906), pts. 1, pp. VIII+839; 2, pp. 1095*).—The bibliography of physiology, including experimental psychology, pharmacology, and experimental pathology, is continued in this volume of the international catalogue (E. S. R., 16, p. 689). Part 1 is the author catalogue and part 2 the subject catalogue. The present volume contains material received between May, 1905, and May, 1906.

ANIMAL PRODUCTION.

Some observations and experiments on the natural and artificial incubation of the egg of the common fowl, A. C. Eycleshymer (*Biol. Bul. Mar. Biol. Lab. Woods Holl, 12 (1907), No. 6, pp. 360–374*).—A series of experiments on the developing chick showed that frequently variations in development were so great that the value of the results was materially decreased. The author attempted, therefore, to secure additional data regarding the effect of the position of the egg, turning the egg, cooling, ventilation, and moisture of the air.

Special attempts were made to secure uniformity with respect to size and other conditions in the Plymouth Rock eggs used. The eggs were tested by transmitted sunlight, and those in the same stage of development were selected for experimental purposes.

In tests undertaken to ascertain what position eggs occupy during natural incubation it was found that an oblique position was usual, but that this was a factor of little or no importance. The observations and experiments with artificial incubation on the other hand led to the deduction that when the supply of fresh air (oxygen) is inadequate the oblique position of the egg with the small end up brings the embryo in closer contact with the air chamber and is decidedly advantageous. When there is an abundant supply of fresh air there is little to gain in placing the eggs obliquely.

As shown by observations with nests having felt sides and concave glass bottoms, eggs are turned partially or completely by hens at least five times during any given day, which is much more frequently than has been supposed. "The hen turns the eggs in two ways. If a sitting hen be watched as she returns from feeding to sitting, it will be seen that she moves her body rapidly from side to side. Whether the object be to turn the eggs is uncertain. Probably the first object is to bring the surface of the body in the closest possible contact with the growing embryos. Accidentally or purposely she also turns the eggs. This is not only true of the hen returning from feeding, but also when on the nest, for she is frequently observed moving about and settling down with the same characteristic lateral movements. Sometimes there are so many eggs in the nest or they are so widely scattered that the hen fails to properly cover them. When such conditions occur the hen invariably uses her beak to bring the outlying eggs in contact with her body. Not only does she frequently thus turn the eggs, but also she very often reaches beneath her body and turns the eggs lying near the center of the nest. Why she does this is a question which awaits an answer." The experiments made with incubators indicated that frequent turnings, at least five, gave the best results.

In a study of the temperature of eggs with reference to incubation, a series of observations is reported on the daily temperature of hens. Special self-registering thermometers fastened to blocks with the upper surface egg-shaped, which were placed under the hens in the nests, were used, and also thermometers placed in the groin. By the first method the readings ranged from 101.5 to 106° F., and by the second method, in which the hens were disturbed and the temperature was consequently somewhat higher than normal, from 102 to 107.4°.

The temperature of eggs during incubation was also measured, special precautions being taken to insure the maintenance of constant temperature. The range in temperature noted was from 98 to 103°. "These observations show that the proper incubating temperature of the egg is about 100° for the first week, 101° for the second, and 102–103° for the final week."

From tests of temperature of incubators and eggs, the author is of the opinion that the most favorable temperature within the egg chamber of an incubator is close to 102–103° in the first half of the incubating period and 103–104° for the latter half.

"In any consideration of temperature the fact must be kept in mind that as the chick grows it gives off more and more heat, so that if an incubator of 200-egg capacity were entirely without artificial heating, the temperature would be much higher than that of the surrounding atmosphere; it consequently follows that less artificial heat is necessary during the later stages of incubation. The 102–103° in the earlier stages is largely artificial heat, while the 103–104° in the later stages would be the combined animal heat given off by the egg and the artificial heat supplied by the heat radiator."

In natural incubation the hens leave the nests from time to time for food and in this way the eggs are, of course, cooled. "It may be stated with a fair degree of certainty that the cooling of the eggs is due to the necessity of obtaining food, and in no way fundamentally affects the growth of the chick when there is an abundant supply of fresh air. There is not the least doubt, however, but what it has a beneficial influence in cases of poor ventilation, and since no incubator is supplied with too much, it probably is best to adopt the common practice of cooling the eggs. In so doing it would not seem advisable to cool the eggs for more than 20 to 30 minutes each day for the first 15 or 18 days."

In tests of the effect of ventilation on eggs it was found that in an incubator with special ventilation 85.7 per cent of the fertile eggs hatched and in an incubator without ventilation 44.3 per cent. The amount of ventilation necessarily involves a consideration of the moisture content of the air and daily hygrometer tests were made with a view to ascertaining the amount of moisture which exists in the nests. "It was found on the average that the egg during natural incubation loses about 13 per cent of its original weight. It was also found by experiment that the evaporation could be lessened until the egg lost but 9 per cent of its original weight and still give a healthy chick. It was likewise learned that evaporation could be increased up to about 20 per cent and the eggs give rise to perfect chicks. It would thus appear that the moisture in the incubator should be so controlled that it will allow the evaporation of about 13 per cent of the orginal weight of the egg."

Condimental stock foods, F. W. WOLL (*Wisconsin Sta. Bul. 151, pp. 40*).—Analyses were made of 30 samples of condimental stock feeds. The author calls attention to the fact that in most of the samples the ash content was high, ranging from 5 to nearly 50 per cent, owing to the presence of large quantities of inorganic materials, like common salt, Epsom and Glauber salts, lime carbonate, lime sulphate, iron sulphate, etc., common salt being present in the largest quantities. The protein content ranged from 2.25 to 52.38 per cent.

"Most of the stock foods do not contain more valuable feed materials than oil meal or even wheat bran, and many contain less, as might be expected when we consider the character of the materials entering into the composition of these foods. However, since the manufacturers do not make special claims for nutritive properties in their 'foods,' this fact is not very important, and the value of the condimental stock foods must be decided on the basis of the medicinal properties of the drugs [ginger, gentian, fenugreek, pepper, sulphur, and similar materials] contained therein."

Data regarding the character of the ingredients in condimental stock foods, the results obtained in feeding tests with such materials, and formulas for making such foods at home are summarized. The author's conclusions follow:

Stock foods are of no benefit to healthy animals when fed according to manufacturers' directions "either as to increasing the digestibility of the feed eaten or rendering it more effective for the production of meat, milk, wool, etc.

"They are of no benefit as a cure-all for diseases of the various classes of live stock; neither do they possess any particular merit in case of specific diseases, or for animals out of condition, off feed, etc., since only a small proportion of ingredients having medicinal value is found therein, the bulk of the foods consisting of a filler which possesses no medicinal properties whatever.

"Exorbitant prices are charged for these foods, as is natural, considering the extensive advertising the manufacturers are doing, and the liberal commissions which they pay agents and dealers. The large sales of stock foods are doubtless mainly to be attributed to these facts.

"By adopting a liberal system of feeding farm animals and furnishing a variety of feeds, good results may be obtained without resorting to stock foods of any kind. If a farmer believes it is necessary to feed stock foods at times, he can purchase the ingredients at a drug store and make his own stock foods at a fraction of the cost charged for them by the manufacturers. He will then have the additional satisfaction of knowing just what he is feeding, and of feeding a concentrated 'food' instead of one largely diluted with nonmedicinal ingredients."

Commercial feeding stuffs, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul. 131, pp. 8, figs. 2*).—Of the 112 samples of commercial feeding stuffs examined under the provisions of the State law, 45 represented guaranteed goods (cotton-seed meal, linseed meal, gluten feed, distillers' dried grains, brewers' dried grains, molasses feed, alfalfa feed, hominy feed, cereal breakfast food by-products, and animal meals) and the remainder unguaranteed feeds, namely, wheat offals and home-grown provenders. Of 14 samples of cotton-seed goods 8 were below guaranty, as were also 4 of the 5 samples of distillers' grains, a sample of oat feed and molasses feed, and a sample of alfalfa meal. The mixed feeds, bran, middlings, red dog flour, and the provenders of local manufacture were found to be of good grade.

A large proportion of the samples were also examined as to their weed seed content and germination, and the viability of the seeds and character of the weeds tested in pot experiments. "The by-products of the oil mills, the distilleries and the breweries, of the glucose and hominy works, and of several flour mills passed muster; but a single oat feed, a guaranteed wheat (mixed) feed, and every molasses feed carried more or less weed seeds, and these were viable, able to germinate and flourish . . . save in one case. . . .

"The buyer of a ton of one brand of these molasses feeds purchased therein three weed seeds for every square foot of a hundred-acre farm. . . .

"It is a matter of common knowledge that there are sold yearly hundreds of carloads of wheat screenings (which being interpreted means in the main weed seeds screened from wheat prior to the milling process). Sheep and poultry handle them well; but the digestive system of neither horse nor cow is able to destroy them. To employ materials carrying viable weed seed in the mixture of 'dairy' or 'horse' feeds, even though they are plastered over with molasses, is little short of atrocity."

Kansas law regulating the sale of concentrated feeding stuffs, C. W. Burkett and J. T. Willard (*Kansas Sta. Bul. 146, pp. 217–224*).—The Kansas State feeding stuff law provides for the registration of concentrated feeding stuffs, analysis of samples by station officials, and an inspection tax. Violations of the law are punishable by fines.

The chemical composition of meadow hay from different Austrian farms in 1903, F. Hanusch (*Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 3, pp. 81–85*).—Sixty per cent of the samples analyzed were classed by the author as of medium quality and 40 per cent as inferior.

Poisonous beans, J. Hendrick (*Trans. Highland and Agr. Soc. Scot., 5. ser., 19 (1907, pp. 139–144*).—In recent years many cases of cattle poisoning have been reported which were traced to beans imported from Java. The author has studied the question of such poisoning extensively and summarizes his results in the present paper. As he points out, the beans contain a glucosid which liberates hydrocyanic acid when acted upon by enzym or when treated with acid. Boiling the beans destroys the enzym and renders them harmless. Similar poisonous properties have been attributed to Rangoon or Burma beans, and until definite information is forthcoming the author insists that such beans should not be used.

The use of sugar, sugar beets and their by-products as feeding stuffs in 1906, A. Schift (*Wiener Landw. Ztg., 57 (1907), No. 30, pp. 289, 290*).—A summary and discussion of experimental data on the use of these products in animal feeding, which shows that their importance is appreciated.

The influence of proteolytic enzyms in feeding stuffs, W. Grimmer (*Biochem. Ztschr., 4 (1907), No. 1, pp. 80–98*).—The autodigestion of horse beans, vetch, barley, and oats was studied in neutral, acid, and alkaline mediums. On an average 17.44 per cent of horse bean protein, 22.82 per cent of vetch protein, 8.90 per cent of oat protein, and 5.02 per cent of barley protein were, in experiments in vitro, rendered soluble by the ferments present in the raw material. The character of the protein cleavage products was studied as well as the amount.

The results indicate that proteolytic enzyms in oats and barley are similar and resemble tryptic ferment. Horse beans, the author concludes, contain only one proteolytic enzym, and vetch probably more than one.

The possible importance of the enzyms of uncooked foods in the feeding of man and animals is discussed and, in the author's opinion, the proteolytic ferments normally present may be, under certain conditions, decidedly valuable.

Feeding experiments at the zootechnic laboratory, L. Picollo (*Bol. Agr. [São Paulo], 8. ser., 1907, No. 2, pp. 64–71*).—A brief account is given of the purpose and aims of experiments undertaken to determine the relative digestibility and nutritive value of local-grown and imported feeding stuffs. The data recorded include the kind and amounts of feed eaten, the water drank, and the weight of the feces excreted. The tests were made with a mare, a mule, and a heifer.

Beef production, H. W. Mumford (*Urbana, Ill., 1907, pp. 209, pl. 1, figs. 24*).—In this volume, which is based largely on the author's extensive investigations carried on at the Illinois Station and which is designed as a text-book for class-room work and as a general reference handbook, the author discusses the purchase and characteristics of cattle for feeding purposes, the cost of feeding, rations suitable for different conditions, baby beef, Christmas beef, feeding for the home market, fitting steers for exhibition, cattle in the feed lot, buildings and other equipment for cattle feeding, insect enemies and diseases, breeding beef cattle for market, and related questions.

"The arrangement of matter is designed to suit the demands both of the actual cattle feeder and of the student; to serve both as a ready reference guide—a text adapted to the progressive pedagogic presentation of the subject in the class room and a treatise conveniently arranged in logical order for the general reader interested in the subject."

Economical rations in beef production, H. R. Smith (*Nebraska Sta. Bul. 100, pp. 40, figs. 14*).—Several feeds supplementing a basal ration of shelled corn, snapped corn, and corn stover were tested and the results discussed in comparison with earlier work, of which the present study is a continuation (E. S. R., 18, p. 362).

With wheat bran as a supplement to the basal ration the average daily gain per head was 1.76 lbs., with linseed meal 2.33 lbs., with cotton-seed meal 2.11 lbs., and with alfalfa hay 2.42 lbs. Each of the lots comprised 10 steers, and the tests covered 20 weeks. With these lots the grain ration was increased as the test progressed and during the last 3 months the steers were given all the grain they would eat, which was abut 25 lbs. per head. On a lighter feed of shelled corn (14 lbs. per head per day) with snapped corn, alfalfa hay, and corn stover a similar lot of steers fed 24 weeks made an average daily gain of 2.01 lbs. per head. With all the lots the range in feed eaten per pound of gain was from 13.73 lbs. with the oil meal to 19.25 lbs. with the lot fed wheat bran, and the cost of feed per pound of gain (making no allowance for gains made by pigs following steers) from 6.99 cts. with the lot fed alfalfa hay to 10.49 cts. with the wheat bran ration. In the case of the lot fed wheat bran there was a calculated loss, including pork made by pigs following steers, of $3.94. With the other lots there was a calculated profit ranging from $1.32 with the cotton-seed meal ration to $6.38 with the alfalfa hay ration.

Data are given regarding the profit obtained in feeding a light ration of shelled corn with snapped corn, corn meal, corn fodder, alfalfa hay, and corn stover, but the test is not reported in full.

Some of the general conclusions drawn from this test and earlier work follow:

"Alfalfa hay with corn alone gives large and profitable gains.

"The use of well-cured corn stover with alfalfa and corn, while it may not produce larger gains, will make the gains less costly because of its low market value, thereby increasing the profits over corn and alfalfa alone. . . .

"The results of 2 experiments indicate that linseed meal is a little more valuable than cotton-seed meal and much more valuable than wheat bran for supplementing corn when fed with prairie hay or corn stover.

"When alfalfa is made at least half of the roughness with prairie hay or corn stover, good gains may be made and at less cost than when no alfalfa is fed, the protein being supplied by the use of linseed meal. In other words, it is possible to grow protein on the farm at a price much below what it will cost on the market in the form of some commercial protein food. . . .

"The results of a single experiment in which but little more than half a full feed of corn was supplied two lots of fattening steers suggest the possibility of making a larger use of hay in finishing cattle for market than is ordinarily made and at less cost, especially where hay is relatively low and corn high in price.

"From a commercial point of view the results of this entire series of experiments go to show that cattle feeding can be made profitable when discretion is used in the selection of foods for the ration. . . . Good feeding will make our corn bring more as beef than when sold direct to the elevator companies, even though the selling price of finished cattle is not far in advance of cost price, as was true in many of these experiments. The importance of manure and the growing of alfalfa and clover as agencies contributing to the maintenance and increase of land fertility argue further for this mode of selling a larger part of our annual corn crop. The cattle industry deserves much greater attention in this State than has been given it in the past."

The bulletin also contains some illustrations showing prize winners exhibited at the International Live Stock Show, 1906, by the department of animal husbandry of the University of Nebraska.

Dried beet pulp for fattening steers, R. S. Shaw, and H. W. Norton, Jr. (*Michigan Sta. Bul. 247, pp. 157-165*).—In one of the 3 tests with steers or younger animals which are reported, corn meal and oil cake and dried beet pulp and oil cake 5: 1 were fed. In the other two tests the ratio of the two feeds to oil cake was 5:2. A ration of corn meal, dried beet pulp and oil cake 5:5:4 was also included in 2 of the tests. The coarse fodder consisted of clover hay or timothy hay with corn silage in 2 tests.

The 3 tests covered respectively 84, 112, and 120 days. On an average the daily gain per head on the corn meal ration was 1.466 lbs., on the beet pulp ration 1.441 lbs., and on the ration containing both corn meal and beet pulp 1.561 lbs. The cost of a pound of grain in the 3 cases was 8.87, 7.17, and 7.23 cts.

"The absolute gains produced by feeding beet pulp were practically the same as from feeding corn meal.

"The gains of the pulp-fed steers were in the nature of growth and development, the corn meal produced fat and finish. As a result, at the end of the feeding period, the corn meal steers were in better condition for market than the others.

"For growing animals, beet pulp produced the greatest gains. For animals in a condition for finishing, corn meal gave the most rapid gains.

"From this it would be safe to conclude that in the earlier part of the feeding period beet pulp could be fed in a larger quantity to advantage, because of its cheapness and at the same time ability to produce gain rapidly. During the finishing period it should, however, be replaced at least in a large measure by corn meal, which possesses more value for finishing purposes. The corn meal is a much more concentrated feed, hence its especial value for forcing at the close of the feeding period when beet pulp could not be used on account of the bulky character rendering it impossible to feed sufficient quantity for the best results. These trials show that a 1,000-lb. steer will not consume over 10 lbs. of dried beet pulp in a day."

Feeding calves with starch and skim milk, A. Gouin and P. Andouard (*Bul. Sta. Agron. Loire-Inf., 1905-6, pp. 48-51*).—According to the authors' extended observations much larger quantities of starch may be fed than the 50 gm. per liter of skim milk recommended by some other investigators.

Milk emulsion for calf feeding, G. Hangel (*Wiener Landw. Ztg., 57 (1907), No. 36, p. 347*).—When an emulsion of palm fat and skim milk was substituted for whole milk in calf feeding very satisfactory results were obtained, according to experimental evidence, which is briefly reported.

Experiments on calf feeding, A. Gouin and P. Andouard (*Bul. Sta. Agron. Loire-Inf., 1905-6, pp. 52-82*).—In the studies reported a number of different rations were fed, the feed being regulated in accordance with the weight of the animal at different stages of growth. Requirements for growth and maintenance and related questions are discussed. In the authors' opinion, powdered green bone of good quality, such as is used as a fertilizer, is a very valuable constituent of the ration for calves.

Tankage for hogs in cattle feed lots, B. E. CARMICHAEL (*Ohio Sta. Circ. 73, pp. 4*).—Definite information gathered from 45 Ohio cattle feeders showed that only 10 supplied other feeds than corn to pigs following steers. The remaining 35 feeders either supplied no feed in addition to what the pigs could gather or else fed them corn. As the steers are very largely fattened on corn it follows that the pigs are fattened almost exclusively on this grain. Tests were therefore undertaken to determine whether the prevailing practice can be improved.

Two lots of 7 steers each were fed a ration of shelled corn, cotton-seed meal, corn stover, corn silage, and mixed hay, while 2 similar lots were fed a dry ration made up of the same materials, with the silage omitted. For 63 days 3 pigs followed each lot of cattle. They were then replaced by 4 thinner pigs and the test continued for 56 days. In addition to what they could gather, 1 lot of pigs following the silage-fed steers and 1 lot following the steers receiving no silage, were fed ⅓ lb. per head daily of digester tankage.

Considering the test as a whole, the pigs fed the tankage gained 1,230 lbs. and those fed no tankage 808 lbs., a gain of 52.22 per cent in favor of feeding tankage.

"The tankage was fed in the form of a thin slop, once daily. It may be very conveniently fed in this manner and was greatly relished by the hogs, in fact, they exhibited an almost ravenous appetite for it. . . .

"It is possible that the tankage-fed hogs consumed somewhat more corn than did those which received no tankage. Definite data are not at hand in regard to this matter, since in each of the lots a small amount of the grain was left in the manure by the hogs. It seems certain, however, that the gains made by the tankage-fed hogs are cheaper as well as larger.

"While, on account of its cheapness as a carrier of protein and ash convenience for feeding, digester tankage was used in the work reported herein, it is believed that other feeds, such as linseed-oil meal, soy beans, skim milk, buttermilk, or middlings, would greatly increase the efficiency of the 'cattle hog' in making economical gains. Feeders need, however, to exercise keen discrimination in the purchase of feed stuffs, for there is a likelihood of a heavy demand for certain feeds making it possible for the manufacturers to raise prices beyond the amount justified by the feeding value.

"Further work is needed along this line to determine what feeds are best suited for this purpose, and in what amounts they should be fed."

This line of experimenting will be continued at the station.

Animal husbandry in Denmark, 1906, A. APPEL (*Tidsskr. Landökonom., 1907, No. 6, pp. 329–344*).—A general survey.—F. W. WOLL.

Cattle raising, VICOMTE DE VILLEBRESME (*Bul. Soc. Agr. France, n. ser., 39 (1907), May 1, Sup., pp. 377–388*).—The French cattle-raising industry is discussed with special reference to breeds, feeding, profits, and related questions.

Sheep on arable farms, J. WYLLIE (*Trans. Highland and Agr. Soc. Scot., 5 ser., 19 (1907), pp. 147–161*).—The data summarized have to do with the feeding, care, and management of sheep under local conditions.

Ostrich raising in Africa, D. KURCHOFF (*Tropenpflanzer, 11 (1907), No. 5, pp. 302–314*).—A summary and discussion of data regarding ostrich raising in Africa.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Investigations on the proteid requirement of milch cows, O. KELLNER (*Fühling's Landw. Ztg., 56 (1907), No. 17, pp. 589–593; Milch Ztg., 36 (1907), No. 40, pp. 469, 470*).—The author considers briefly some of the results obtained in metabolism experiments with cows, the object of which was to determine the minimum amount of food proteid requisite for the production of a definite quantity of milk. With a ration rich in carbohydrates and a supply of nitrogenous materials only equal to the total amount in the excretory products and in the milk, the cows continued for a long time to give a considerable quantity of milk of good composition, almost the whole quantity of digestible protein in excess of their maintenance requirements appearing in the milk. The author believes that though the results obtained indicate that milk-giving animals may be made to be especially economical of the protein in the ration, they do not warrant the use of such small quantities of protein in feeding.

Some attention is also paid to results obtained in experiments on the substitution of ammonium acetate for part of the digestible protein in the rations. With an abundance of carbohydrates in the ration the ammonium salt seemed to be able to take the place of some of the food proteid in milk production. The author suggests that it was "apparently converted into proteid in the chyme," perhaps through the influence of bacteria.

The effect of rations rich and poor in fat on milch cows (*Landw. Jahrb., 36 (1907), No. 4, pp. 724–738*).—In 3 corresponding feeding periods the rations contained 2.77 kg. of digestible protein and 12.20 kg. of digestible nitrogen-free substances per 1,000 lbs. of live weight, but in the first and third periods the quantity of fat was only 0.64 kg., whereas in the second it was 1.17 kg. The quantities of milk and fat produced daily by each of the 15 cows on these rations are given. From the results obtained, the conclusion is drawn that the effect of the one ration is the same as that of the other.

The effect of emulsified and nonemulsified food fat upon milk production, C. BEGER (*Landw. Vers. Stat., 67 (1907), No. 1–2, pp. 1–25*).—In continuation of previous work (E. S. R., 18, p. 171), the author fed 3 goats with whole milk as a typical emulsified fat, and with skim milk and melted butter fat as a source of nonemulsified fat. From the results of the experiments the conclusion was drawn that the fat as an emulsion in the form of whole milk had the greater influence upon the milk secretion. The effect upon the body weight of the animals was so small and so variable that no conclusion regarding it could be drawn.

Should concentrated feeds be fed wet or dry? LEITHIGER (*Sächs. Landw. Ztschr., 55 (1907), No. 25, pp. 693–695*).—From the better milk production and gain in body weight obtained in experiments with 8 cows fed their concentrates for one period wet and for another dry, the author concludes that it is more desirable to feed concentrates dry.

On the histology of the milk glands of the cow, P. LENFERS (*Ztschr. Fleisch u. Milchhyg., 17 (1907), Nos. 10, pp. 340–350; 11, pp. 383–390; 12, pp. 424–449*).—In these investigations, the author used tissues from the milk glands of cows of different ages, at different periods during pregnancy, at different stages in the lactation period, and of cows dry for different lengths of time. He describes his method of preparing the tissues for microscopical examination, and discusses his data with special regard to the condition of the milk glands before the birth of the first calf, during lactation, and during involution, comparing his own conclusions with the opinions of previous investigators. A bibliography is appended to the article.

Contribution to the knowledge of the composition of the fat of cow's milk, W. FLEISCHMANN and H. WARMBOLD (*Ztschr. Biol., 50 (1907), No. 3, pp. 375–392*).—As reckoned from the quantities of glycerin and volatile and nonvolatile fatty acids determined in 4 samples of milk fat, the elementary composition of the fat averaged 75.25 per cent carbon, 11.86 per cent hydrogen, and 12.89 per cent oxygen. In the average of 26 analyses of 9 samples of lactic acid-free pure milk fat separated by melting, the elementary composition was 74.78 per cent carbon and 11.46 per cent hydrogen.

On the spontaneous separation of a casein compound from milk, L. Preti (*Ztschr. Physiol. Chem., 53 (1907), No. 3–5, pp. 419–426*).—In milk preserved a year by the addition of chloroform, a rich white precipitate formed in the bottom of the flask without changing the reaction of the milk. Upon investigation this precipitate was considered to be a mixture of calcium phosphate and calcium caseinate. The author could not determine the nature of the casein, whether acid casein or rennet casein, and therefore could not decide whether the gradual separation of the precipitate occurred as a purely physical phenomena or under the action of a ferment.

The action of dilute acids upon casein, L. L. and D. D. Van Slyke (*Amer. Chem. Jour., 38 (1907), No. 4, pp. 383–456, figs. 14*).—This has already been abstracted from another source (E. S. R., 19, p. 173).

The hydrolysis of the sodium salts of casein, L. L. and D. D. Van Slyke (*Amer. Chem. Jour., 38 (1907), No. 5, pp. 619–626, figs. 2*).—This has already been abstracted from another source (E. S. R., 19, p. 174).

A contribution to knowledge regarding goat's milk and butter, H. Sprinkmeyer and A. Fürstenberg (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 6, pp. 388–391*).—The milk of each of 10 goats at the beginning of the lactation period was tested separately. The goats were milked at morning, noon, and evening. In the average of the data for 1 day the quantity of milk for the different milkings was respectively 969, 522, and 668 gm., the lactodensimeter reading at 15° C. was 30.7, 29.0, and 31.1, and the fat content was 3.91, 4.95, and 4.38 per cent. In the butter made from the milk the refractive index at 40° C. ranged for the different animals from 41.1 to 44.3, the Reichert-Meissl number from 20.3 to 29.1, the saponification number from 226.1 to 242.4, and the iodin absorption number from 26.9 to 38.9.

Dictionary of dairying in all countries, B. Martiny (*Wörterbuch der Milchwirtschaft aller Länder. Leipsic, 1907, pp. XI+142*).—A collection of popular expressions and technical terms pertaining to dairying and also to cattle breeding in use in different countries, with explanations of their meanings.

Review of the work of the 1906–7 season, D. Cuddie (*New Zeal. Dept. Agr., Dairy Div. Bul. 10, pp. 52, pls. 13; Ann. Rpt. 1907, pp. 5–22*).—The purpose of this publication is merely to "furnish a general outline of what has been done by the division, with some observations on matters affecting the dairy industry."

Handbook of information regarding milk, H. Rievel (*Handbuch der Milchkunde. Hannover, 1907, pp. X+376, figs. 35*).—In this volume, which is virtually a text-book on milk, the author presents a considerable amount of data and other information of value to those interested in the production and distribution of milk. The book is divided into several sections, which discuss, respectively, the properties of normal milk as affected by differences in breed of cattle or in individuality, by age, feeding, disease, etc.; the dangerous qualities of milk owing to diseases of the cows; measures for the prevention of the dangers in the use of milk, such as sterilization and pasteurization; the use of milk as a food for infants and children, with special consideration of the various methods of preparing the milk; and various topics concerned in milk control. An appendix gives a number of examples of police ordinances for the regulation of the milk industry in several cities in Germany.

American milk and milk standards, W. Frear (*Proc. Conv. Nat. Assoc. State Dairy and Food Depts., 10 (1906), pp. 172–194*).—"The purpose of this paper is to present a few facts concerning the composition of American milk in its relation to the chemical limits fixed in American legal standards, and especially those of the United States standard."

After discussing data obtained from a great many sources, the author concludes, that "from all these facts it appears that in the United States the general supply of milk for household use has an average fat content of from 3.8 to 4 per cent; that when the herds are turned to pasture a reduction to the average extent of 0.2 or 0.3 per cent occurs in the fat, and that the daily variations of herd's milk below the average do not usually exceed 0.15 to 0.20 per cent. It furthermore appears that, while the lowland breeds are being more largely used in certain communities, thus reducing the average richness of the milk there produced, with proper care in the feeding and in the selection of the family strain of these breeds, the tendency toward such reduction can be kept from going to an extreme. Finally, a widespread movement toward higher fat standards is apparent in communities where the 3 per cent standard now appears.

"With respect to the solids, on the other hand, the tendency is to swing back from the higher standards of 13 per cent to a position of 12 or 12.5 per cent."

Third International Dairy Congress, held at The Hague, September, 1907 (*Hyg. Viande et Lait, 1 (1907), No. 9, pp. 428-432; Indus. Latt. e Zootec., 5 (1907), No. 18, p. 137; Indus. Lait. [Paris], 32 (1907), No. 38, pp. 693-698*).—The rules and regualtions of the congress, the programme for the different sections, and the resolutions finally adopted by the several sections of the congress on laws and regulations, industry, and hygiene, pertaining to dairying and dairy products are given.

A statute regarding the care of milk and various milk products in Brunswick (*Veröffentl. K. Gsndhtsamt., 31 (1907), No. 38, pp. 968-971*).—The ordinance of the city of Brunswick governing the inspection of milk and milk products, the designation and quality of different kinds, the care and handling of milk, the requirements to be observed during the sickness of milk producers' families or helpers, the care of milk vessels, and the punishment for violation of the statute are given.

City milk inspection, J. Q. EMERY (*Proc. Conv. Nat. Assoc. State Dairy and Food Depts., 10 (1906), pp. 89-95, figs. 3*).—The author discusses the results obtained in the examination of milk in a number of cities in Wisconsin, and calls attention particularly to the use made of the Wisconsin curd test which he designates as "the simplest, quickest, most practicable and effective method known, whereby the imperfections present in milk can be readily and accurately ascertained, not only by the butter maker and cheese maker, but by the city milk inspector and the housewives as well."

Perhydrase milk according to Much and Römer, H. STRELINGER (*Ztschr. Fleisch u. Milchhyg., 18 (1907), No. 1, pp. 15-21*).—The author gives the details of his application of the method of Much and Römer for the commercial production and distribution of perhydrase milk. He states that milk thus produced will keep for months, and that it can then be freed of its hydrogen peroxid and will be so little changed that it tastes like fresh raw milk. The article includes reports by different investigators on bacteriological and hygienic tests of the product and on the results of experiments in feeding the milk to infants.

The conservation of milk by hydrogen peroxid, C. PORCHER and E. NICOLAS (*Rev. Gén. Méd. Vét., 10 (1907), No. 115-116, pp. 345-358*).—The authors review the deductions from the research of different investigators regarding the use of this antiseptic for the preservation of milk, and conclude that there is still need for investigation before absolutely certain decisions can be made with reference to the desirability of its use, and that, as is true of any method of preserving milk, it should not be used in any case except when the milk is produced under strictly hygienic conditions.

The detection of formaldehyde in milk, C. L. PENNY (*Delaware Sta. Rpts. 1904–1906, pp. 38, 39*).—The presence of formaldehyde in milk when added in solutions as dilute as 1 part of pure formaldehyde to 100,000 parts of milk was detected by means of the hydrochloric acid and ferric chlorid test immediately after addition and up to 19 days after. The conclusion from the tests was that "any amount of formaldehyde capable of preserving milk from curdling can be certainly detected so long as it preserves the milk, and, as a practical question, this is all that could be desired."

The cost of food in the production of milk, J. SPEIR (*Jour. Bd. Agr.* [*London*], *14* (*1907*), *No. 6, pp. 321–334; abs. in Canad. Dairyman, 3* (*1907*), *No. 41, p. 672*).—The author discusses the data regarding food consumed and milk and butter fat produced that have been obtained by milk record associations in southwestern Scotland. According to the data obtained during the winter and spring months up to May, 1907, the average cost of milk per gallon (10 lbs.) was 8.72 cts.

Butter and milk tests at the Derby Show, 1906, E. MATHEWS (*Jour. Roy. Agr. Soc. England, 67* (*1906*), *pp. 189–201*).—Data obtained in tests of the quantity and quality of milk and butter yielded by several different breeds of cattle are reported. The results of 2 experiments in the dairy are also given, in one of which the author believes he ascertained that the public generally do not know the taste of genuine unadulterated butter, and in the other he demonstrated that the method of ceasing to churn when the butter is in a granular condition was preferable to that of churning the butter into a lump.

Butter, 1906–7, T. MACFARLANE (*Lab. Inland Rev. Dept.* [*Canada*], *Buls. 131, pp. 15; 133, pp. 4*).—Bulletin 131 is a report of the results of analyses of 101 samples of butter collected in 1906. Of these, 90 samples were found to be genuine, 4 doubtful, and 7 adulterated. Bulletin 133 gives the results of an examination of 881 samples collected in 1907. From the butyro-refractometer test, 868 were judged to be genuine butter, 5 were doubtful, and 8 contained foreign fat. The results of more complete tests of these 8 samples and 2 of the doubtful ones are given.

A comparison of anilin and anatto butter colors in butter making, E. H. FARRINGTON and M. MEYERS (*Wisconsin Sta. Bul. 152, pp. 19, fig. 1*).—Three brands of each class of colors were compared as regards the imparting of an objectionable flavor to the butter and the holding of the color when the butter is kept in cold storage. The conclusions drawn are as follows:

"First, some of the brands of vegetable butter color now on the market are weaker than the analin butter colors. Nearly twice as much vegetable color was needed in some cases to produce the same shade of color in butter as was given by the anilin color.

"Second, when the change was made from vegetable to anilin butter color, some 15 years ago, butter makers were so accustomed to the weaker anatto color that they added too much of the stronger anilin color. This had a tendency to gradually accustom the consumer to a more highly colored butter than formerly had been made.

"The natural color of June butter is a sufficiently high color, and when only enough vegetable color is added to produce this shade there will be no danger of using so much as to impart a butter color flavor to the butter.

"Third, the vegetable colors now on the market impart a rather greenish-yellow shade to the butter. This is quite different from the bright or reddish-yellow given to the butter by the anilin colors.

"Fourth, some brands of vegetable color contain a decided flavor, imparted to them by the oil used in making the color. This flavor may be distinctly noticed in the butter when large quantities of such brands of color are used.

"Fifth, a great improvement in the strength and flavor of certain brands of vegetable butter color was noticed during the year these experiments were conducted, which suggests that the vegetable butter colors may eventually be improved so as to compare favorably with the anilin butter colors.

"Sixth, when butter was held in cold storage at 5° below zero, no difference was noticed in the uniformity or the depth of color in the lots of butter to which anilin and vegetable coloring was added. Over 50 tubs of butter were held in storage for different lengths of time, some of them being taken out when the butter was nearly a year old. Neither the vegetable nor the anilin colored butter showed any indication of fading or changing color while in storage.

"Seventh, butter can be satisfactorily colored with a vegetable color."

The distribution of lactic-acid bacteria in curd and cheese of the Cheddar type, F. C. HARRISON (*Proc. and Trans. Roy. Soc. Canada, 2. ser., 12 (1906), Sec. IV, pp. 83-87, pls. 5*).—The author briefly describes his investigations on the distribution of bacteria in Canadian Cheddar cheese and discusses, with illustrations, his microscopic examination of curd and cheese (1) at cutting time, (2) when cooking temperature was reached, (3) at dipping (running off the whey), (4) at milling, (5) at salting, and (6) in cheese 2 days old. The results confirm the conclusion from previous examinations, that "there is not an even distribution of bacteria throughout the substance of a cheese, and it would therefore seem necessary to modify somewhat our methods of analysis."

Regarding "short" cheese, F. W. J. BOEKHOUT and J. J. O. DE VRIES (*Rev. Gén. Lait, 6 (1907), Nos. 14, pp. 313-323; 15, pp. 345-351, pl. 1; Verslag. Ver. Exploit. Proefzuivelboerderij Hoorn, 1906, pp. 83-98, pl. 1*).—In the manufacture of Edam cheese the ripening process under some conditions yields a hard, chalky, crumbly product, known commonly as "short" cheese.

According to the investigations of the authors this results from an excess of free lactic acid in the curd during ripening. This may be due to faulty manipulation of the curd in the preparation for ripening, leaving in too much lactose from which the lactic acid may be produced, or to the action of certain specially active lactic-acid bacteria. The authors report data of several experiments in which cheese was ripened under the influence of 2 species of lactic-acid bacteria, one of rapid action and one of slow action. In each case the cheese ripened under the influence of the bacteria producing lactic acid in a relatively short time was faulty. The analyses of several of the faulty cheeses compared with a similar number of ordinary cheeses obtained from their experiments showed a much larger quantity of lactic acid in the "short" cheese than in the good cheese.

"Bitto" cheese, G. MELAZZINI (*Indus. Latt. e Zootec., 5 (1907), No. 18, pp. 138, 139*).—A brief article describing this kind of cheese, the importance of its production in different Alpine provinces, some factors of significance in making it, and remarks concerning its sale.

Milk and dairy products, G. MARPMANN (*Nahr. u. Genussmtl., 1 (1907), Abt. 1, pp. 297+VIII, figs. 232*).—This volume, which forms one part of a division, entitled Food Materials from the Whole Animal Kingdom, of a proposed handbook on food materials, discusses the nature and uses of milk and dairy products, and the processes and equipment used in their production.

Annual report on the investigations and progress of the manufacture of sugar, J. BOCK (*Jahresber. Zuckerfabrik [Stammer], 46 (1906), pp. XI+351, figs. 32*).—In this review of the literature of sugar making for 1906, chapter 1 is devoted to the agriculture and chapter 2 to the technology of sugar production. Chapter 3 deals with scientific and technical chemical investigations, the fourth chapter gives some account of patents relating to the sugar industry, and the final chapter contains various statistics, and laws of different countries, pertaining to the production, distribution, and consumption of sugar.

VETERINARY MEDICINE.

Action of various amins on bacteria, particularly the glanders bacillus, M. Nicolle and A. Frouin (*Ann. Inst. Pasteur, 21 (1907), No. 6, pp. 443–447*).—Various amins including piperidin have been shown to exercise a considerable power of destruction upon living proteid substances, particularly in bacteria. This matter was studied in the case of the glanders bacillus. It appears that when the glanders bacillus has been subjected to the influence of piperidin it retains its toxicity only toward animals which have been previously rendered abnormally sensitive to this organism.

Tetanus antitoxin, H. Vincent (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 23, pp. 1193–1195*).—In experiments with small laboratory animals it was found that tetanus antitoxin does not protect the animal against the development of an artificial infection even if administered within 1 hour after the animal has been removed from an autoclave maintained at a temperature sufficiently high to elevate the body temperature of the experimental animal. In cases where the antitoxin was administered immediately after the animal was taken from the autoclave the disease appeared in a chronic rather than in an acute form. These experiments present additional evidence of the influence of heat in rendering animals more susceptible to tetanus.

Accidents following upon vaccination against anthrax, A. Ascoli (*Rev. Gén. Méd. Vét., 10 (1907), No. 110, pp. 49–58*).—While signal success has attended vaccination against anthrax in the hands of expert veterinarians a number of accidents have occurred showing that the virus used for vaccination may vary in virulence at different times and under different conditions.

An investigation of the subject by the author indicated that the attenuated type of virus used in the Pasteur system of vaccination shows marked differential characters with regard to its virulence. On the basis of these observed differences it is possible to distinguish several qualities of virus. The virulence of the vaccine is not increased by passage through laboratory animals and the biological characters of anthrax virus in laboratory animals differ considerably from those of virus obtained from cattle dead of anthrax.

The author believes that anti-anthrax serum has the power of warding off serious troubles as the result of vaccination provided it is used before septicemia has appeared.

An experimental inquiry into the nature of the substance in serum which influences phagocytosis, G. Dean (*Proc. Roy. Soc. [London], Ser. B, 79 (1907), No. B 533, pp. 399–412*).—The results obtained in previous experiments by the author indicate that the sensitizing action of the serum may be due to the combined action of a thermo-stable and a thermo-labile substance, the former being comparable with the sensitizing substance of French authors, and the other resembling an alexin. The dilution of fresh unheated serum does not cause a diminution in the sensitizing power, at least for staphylococcus and tubercle bacilli until the concentration has been reduced to one-fourth. It appears that phagocytosis in dilutions ranging from $\frac{1}{4}$ to $\frac{1}{32}$ is proportional to the square root of the concentration of the serum. The phagocytic index shown by mixtures of heated immune serum and normal fresh serum is greater than either of these sera used separately.

Mammitis produced by acid-resistant bacteria, L. Nattan-Larrier and P. Bovéri (*Compt. Rend. Soc. Biol. [Paris], 63 (1907), No. 24, pp. 15, 16*).—In experiments reported in this paper 12 species of acid-resistant bacteria were used in inoculating laboratory animals for the purpose of comparing the lesions thus produced in the udder with those which occur in tuberculous infection.

When laboratory animals were inoculated in the udder with human tubercle bacilli a mammitis appeared on the fifth or sixth day and became most pronounced on the eighth to the tenth day. The acid-resistant bacteria on the other hand produced a mammitis much more quickly, but the disease while more intense persisted not longer than 9 days. Moreover, the tubercle bacillus produced a suppurative and ulcerative mammitis accompanied with swelling of the glands while these symptoms were absent in the apparently benign form of mammitis produced by acid-resistant bacteria.

Recent work on tuberculosis, T. Kitt (*Monatsh. Prakt. Tierheilk., 18 (1907), Nos. 8–9, pp. 385–411; 10, pp. 445–454*).—A general summary is presented of the more important recent literature relating to the problem of tuberculosis in animals and man, with particular reference to the types of tubercle bacilli observed in different animals, the possibilities of intertransmission, and recent work in vaccination.

Experimental tuberculosis in the guinea pig, A. Calmette, C. Guérin, and M. Bréton (*Ann. Inst. Pasteur, 21 (1907), No. 6, pp. 401–416*).—When either young or adult guinea pigs are fed virulent tubercle bacilli in a fine emulsion, infection invariably takes place. The lesions which develop after such a method of infection are ordinarily in the ganglions or lungs and seldom affect the abdominal organs. Occasionally lesions develop along the trachea. Tubercle bacilli killed by heat or by maceration in alcohol, and bacilli deprived of their waxy membrane, are still toxic for guinea pigs when taken into the alimentary tract.

If tubercle bacilli are killed by chemical substances or by heat and absorbed by the alimentary tract in minute doses and at sufficiently long intervals they confer a remarkable power of resistance toward infection with virulent tubercle bacilli. These effects were produced by using tubercle bacilli macerated for 10 days in an autoclave at a temperature of 37° C. in water containing 10 per cent of salt, or bacilli similarly treated with Gram's fluid, or bacilli subjected to a temperature of 100° C. for 10 minutes.

Transmission of tuberculosis in cases where the udder is affected, Witt (*Berlin. Tierärztl. Wchnschr., 1907, No. 25, p. 491*).—A cow, which upon examination after slaughtering showed evidence of general infection with tuberculosis with a pronounced lesion in the udder, had been used in furnishing milk for a family. In an examination of the family by a physician it was found that one of the children was affected with tuberculous lymphatic glands, believed by the author to be the direct result of drinking tuberculous milk.

A new method of experimental diagnosis of tuberculosis, H. Vallée (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No. 24, pp. 1383–1385*).—The author reports that if tuberculin be rubbed into scarifications of the skin a circular swelling appears around the spot within 36 hours. If the reaction is intense the swelling resembles the verrucose lesions of tuberculosis on the human skin. In drying, the swellings produce epidermal scales.

The penetration of the tubercle bacillus through the skin, J. Courmont and Lesieur (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 22, pp. 1143–1145*).—In experiments with guinea pigs, rabbits, and calves, the author found that the tubercle bacillus could penetrate the apparently intact skin and in almost all instances did so after the skin had been shaved over the area upon which the tubercle bacilli were rubbed. Infection produced in this way led to local skin lesions in some cases and in other cases produced the generalized form of the disease without showing any effect upon the skin. The cutaneous lesions appeared like lupus or scrofula. In rabbits the disease assumed the pulmonary form in a large number of cases.

Cutaneous reaction to tuberculosis, F. Arloing (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 22, pp. 1171–1173*).—Brief reference is made to other recent experiments in making a tuberculin test by rubbing the tuberculin in scarifications of the skin. The author comes to the conclusion that the cutaneous reaction to tuberculin is not constant.

Cutaneous reaction caused by different tuberculins and by human tuberculous serum, F. Arloing (*Compt. Rend. Soc. Biol. [Paris], 62 (1907), No. 23, pp. 1215–1217*).—A claim has been made by a number of authors that specific reactions may be obtained by rubbing tuberculin into scarifications of the skin of animals or human beings. The author tested this matter, using 4 tuberculins obtained from different sources. No specific reaction was obtained in the case of any of the tuberculins, and serum obtained from a tuberculous human being also failed to produce any reaction when rubbed into a skin wound in a tuberculous guinea pig.

Cutaneous reaction to tuberculin, H. Vallée (*Compt. Rend. Soc. Biol. [Paris], 63 (1907), No. 24, pp. 8, 9*).—The results obtained by different authors in rubbing tuberculin into scarifications of the skin have varied considerably. In explaining these differences the author believes that consideration should be had for the fact that some investigators have experimented with animals artificially inoculated with tuberculosis while others have worked upon spontaneous cases of the disease. The results obtained from tuberculin tests by the cutaneous method are more reliable in natural cases of tuberculosis.

Destruction of tubercle bacilli in milk, and vaccination against tuberculosis, E. von Behring (*Behringwerk Mitt., 1907, No. 2, pp. 100, charts 3*).—A general statement is given regarding the effectiveness of a mixture of 1 part formaldehyde and 12½ parts peroxid of hydrogen in destroying tubercle bacilli and other micro-organisms in milk, water, and other fluids. It is claimed for this disinfectant that in the proportions necessary for the disinfection of milk and water it is practically nonpoisonous.

With regard to the addition of formaldehyde alone to milk as a means of freeing the milk from tubercle bacilli the author declares himself in favor of the method with certain qualifications. It is recommended that the maximum amount of formaldehyde be properly made known and that the use of formaldehyde in the disinfection of milk be under strict sanitary supervision.

The greater portion of the pamphlet is occupied with a consideration of the results obtained from the use of bovovaccine, taurovaccine, and other products of the tubercle bacillus prepared and sold under the author's supervision.

The disposition to be made of the meat of animals showing tuberculous infection in the muscular lymphatic glands or bones, L. Marschner (*Ztschr. Fleisch u. Milchhyg., 17 (1907), No. 10, pp. 336–338*).—In the author's opinion if only one tuberculous focus is found in the spinal column by examination of the split surfaces, it is desirable to make a further examination of the tubular bones and of the structure of the vertebræ in order to determine the real extent of the disease. In cases where a few of the lymphatic glands of the muscles in one quarter are found to be affected, it is best to make a thorough examination of that quarter. In fact, the author disapproves of passing the quarter as unqualifiedly fit for human food.

Cattle trypanosomiasis in the Kongo Free State, J. E. Dutton, J. L. Todd, and A. Kinghorn (*Ann. Trop. Med. and Par., 1 (1907), No. 2, pp. 233–271, figs. 4*).—A trypanosomiasis of cattle, due to infection with *Trypanosoma dimorphon*, apparently exists everywhere in the Kongo Free State. In controlling this disease the author recommends that the transportation of cattle from place to place be forbidden as far as is possible and that special care be exercised in the choice of locations for cattle raising in areas where trypanosomiasis is known to occur. Native African cattle and various other domestic animals as well as wild game may acquire considerable immunity to the disease as the result of recovery from an infection.

Concerning the treatment of experimental trypanosomiasis, B. Moore, M. Nierenstein, and J. L. Todd (*Ann. Trop. Med. and Par., 1 (1907), No. 2, pp. 275–284*).—The use of strychnin in cases of infection with *Trypanosoma brucei* has no apparent effect upon the trypanosomes. Atoxyl followed by bichlorid of mercury gives quite satisfactory results, the combination being more effective than atoxyl alone. The experiments reported by the author were made on rats, but it is recommended that the treatment be tested in the case of animals and man infected with trypanosome diseases. Apparently the treatment must begin during the early stages of infection.

Trypanosome transmission experiments, J. E. Dutton, J. L. Todd, and J. W. B. Hanington (*Ann. Trop. Med. and Par., 1 (1907), No. 2, pp. 201–229*).—Experiments were made in the transmission of trypanosomes by tsetse flies. It was found that mammalian trypanosomes may be mechanically transmitted by the bites of various insects. During the development of trypanosomes spherical forms are produced by throwing off the undulating membrane and flagellum. These forms are found both in mammals and insects. The literature of the subject is discussed in connection with a short bibliography.

The transmission of Trypanosoma dimorphon by Glossina palpalis, E. Roubaud (*Ann. Inst. Pasteur, 21 (1907), No. 6, pp. 466, 467*).—Much circumstantial evidence has been accumulated to show that *T. dimorphon* has been transmitted by the agency of tsetse flies. The exact proof of this proposition, however, is not very extensive. The author obtained positive evidence of the agency of *G. palpalis* in transmitting the blood parasite in two instances.

The function of the spleen in trypanosomiasis, A. Laveran and Thiroux (*Compt. Rend. Acad. Sci. [Paris], 145 (1907), No. 1, pp. 14–17*).—It has long been contended that the spleen exercises a beneficial effect in the control of diseases caused by infection with trypanosomes. Experiments undertaken by the authors show that trypanosomes as found in the spleen have exactly the same appearance as those obtained from the general blood circulation. The extract obtained from the spleen exercised no effect upon trypanosomes and the progress of the disease did not appear to be affected by the removal of the spleen. It is possible that the spleen assists in removing the débris caused by the destruction of the red blood corpuscles, but its function so far as trypanasome disease is concerned appears to extend no farther.

The normal temperature of cattle, Kettner (*Ztschr. Veterinärk., 19 (1907), No. 7, pp. 328–331*).—Temperature records were kept as taken at noon and in the evening on 200 adult nonreacting cattle, 91 yearling nonreactors, 30 yearling reacting animals, and 503 adult reacting animals. In adult nonreacting cattle the temperature at midday ranged from 38 to 40° C. The temperature of adult reacting cattle had the same range. The variation in temperature of yearling nonreacting cattle was from 38.5 to 40.6° C. and of yearling reacting cattle from 38.5 to 40.1° C.

The author concludes from these observations that the basal temperature of reacting and nonreacting cattle is the same. As a rule the temperatures of both reactors and nonreactors become slightly higher toward evening. It is believed to be safe, however, to look upon a temperature of 40.1° C. as physiological, provided no recognizable symptoms of disease appear.

A prophylactic method of vaccination against foot-and-mouth disease, J. Oay (*Bul. Soc. Cent. Méd. Vét., 84 (1907), No. 12, pp. 302–308*).—Attention is called to the similarity in the nature and location of the lesions in foot-and-mouth disease and cowpox. As is well known, both of these diseases are transmitted by filterable virus and the micro-organism is not known in either case. The author suggests the possibility that cowpox is a benign form of foot-and-mouth disease. A number of experiments were made during which a vaccine obtained from horses affected with horse pox was used in vaccinating cattle to protect them against foot-and-mouth disease. An immunity of considerable strength was thus produced and the author hopes that this method may prove of some economic importance.

Regulations for government veterinarians in lower Austria (*Tierärztl. Zentbl., 30* (*1907*), *No. 18, pp. 293–298*).—In a discussion of the matter of orders for government veterinarians, together with copies of such regulations in force in lower Austria, it appears that Austria is at present free from foot-and-mouth disease. This fact is learned from a compilation of the reports of various veterinarians, and the condition is believed to be due to the strict regulation of cattle traffic which has been enforced during recent years.

The licking disease of cattle, R. OSTERTAG and N. ZUNTZ (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 2* (*1907*), *No. 6, pp. 409–424*).—The present article is a preliminary report of an investigation undertaken for the Royal Prussian Ministry of Agriculture to determine the cause of the so-called licking disease of cattle.

The results obtained during this investigation indicate that the use of swale hay from native meadows may produce the disease in cattle. The effect seems to be more pronounced after feeding hay from native meadows which have been somewhat improved by cultural methods. The poisonous effect of hay is not equally strong in all years. Apparently the poisonous principle of the swale hay produces a metabolic disturbance particularly in the formation of blood and bones, and, secondarily, a tendency to gnaw and lick all sorts of objects is observed in affected cattle. The nature of the poisonous principle has not been determined. Horses may be safely fed hay which is injurious to cattle. The harmful character of the hay may be entirely removed by steaming.

The development of Piroplasma bigeminum, D. KORSAK (*Arch. Vet. Nauk* [*St. Petersb.*], *37* (*1907*), *No. 4, pp. 315–320, figs. 62*).—It is by no means certain that all of the developmental stages which occur during a complete life cycle of the blood parasite of Texas fever have been made known and arranged in their true sequence. The author has followed the development of this parasite and presents the various stages by means of drawings with explanations in the order in which the different forms occur.

Notes from practice, KIRCHER (*Wchnschr. Tierheilk. u. Viehzucht, 51* (*1907*), *No. 26, pp. 501–504*).—Observations were made on the effect of a 2 per cent creolin dip in treating sheep for scab. It was found that while less dip was required after shearing, the results of dipping were not so satisfactory as when done while the sheep were in full fleece. In several cases a second application of the dip failed to cure the sheep of scab.

Brief notes are also given on irregularities of parturition in domestic animals.

Bare-lot v. grass-lot in relation to stomachal and intestinal parasitism of lambs, W. H. DALRYMPLE (*Louisiana Stas. Bul. 95, pp. 23, pls. 5, figs. 2*).—In previous experiments at the station the bare-lot method greatly reduced the prevalence of nodule disease in lambs, but stomach worms still occurred. The experiment was repeated with treatment added for stomach worms. Four of the experiment ewes received each 4 oz. of a 1 per cent solution of coal-tar creosote and the other 4 received each a mixture of 1 dram carbon bisulphid and 1 dram absolute alcohol in 4 oz. of milk. These treatments were repeated

3 days later, substituting carron oil for the alcohol and milk. The lambs on the grass-lots had similar treatment. The experiment began on March 15, and on August 10 the lambs were slaughtered.

All lambs on the bare-lot were in marketable condition, while only half of the lambs on the grass-lot were in condition. The former were in every way more satisfactory. The bare-lot did not prevent infestation of the lambs with stomach worms, but greatly reduced the number of nodule worms. Rotation of pastures is probably the best method of dealing with stomach worms. Carbon bisulphid gives rather better results as a vermifuge than coal-tar creosote.

The etiology of hog cholera and swine plague, F. Hutyra (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 2 (1907), No. 4–5, pp. 281–309*).—Reference is made to the recent work of American and German investigators who have shown that hog cholera may be caused by filterable virus supposed to contain an ultramicroscopic organism. On account of the close connection which seems to prevail in most outbreaks of hog diseases between hog cholera and swine plague, the author undertook a series of experiments for the purpose of determining whether swine plague might also be due to a filterable virus. The results of these experiments, together with theoretical considerations based on other investigations and the known facts in connection with hog cholera and swine plague, indicate that swine plague is primarily due to the action of a filterable virus.

The author concludes that after primary hog cholera infection has been established in a hog, it may be possible for the characteristic anatomical symptoms of hog cholera or swine plague, or both, to develop secondarily as a result of the action of *Bacillus suipestifer* or *B. suisepticus*. It is believed, therefore, that the anatomical hog cholera and swine plague, whether occurring simultaneously in the same animal or not, are both due to an ultramicroscopic micro-organism found in the filterable virus of hog cholera. These results indicate that hog cholera and swine plague are different manifestations of the same disease, the variation of symptoms being due to the micro-organisms which secondarily infect the hogs.

The horse; its treatment in health and disease, J. W. Axe (*London, 1907, vol. 7, pp. X+188, pls. 14, figs. 92*).—In this part of the author's treatise on the horse, veterinary medicines are discussed and formulas are given for the preparation and administration of medicines in the treatment of animal diseases. The other subjects included in the volume are care of diseased animals, veterinary hygiene, examination of the air of stables, mineral and plant poisoning, and some of the more frequent operations of a surgical nature.

Fatal effects produced in horses by spoiled fodder, W. Zwick (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 2 (1907), No. 4–5, pp. 310–340, pls. 2*).—Opportunity was had to observe a number of cases of the toxic effects of spoiled fodder upon horses, the symptoms in these cases resembling those of enzootic spinal paralysis. The water which the horses received was in satisfactory condition and stables were kept in a sanitary state.

Feeding experiments were made with hay which was apparently in good condition and which there was little reason to suspect. Those experiments indicated that the hay carried a pathogenic coccus which was tested in pure cultures in inoculating mice, rabbits, and horses. It was soon found that the hay in a fresh condition was not injurious, but that the pathogenic cocci became associated with it later partly perhaps as the result of decomposition.

Report of the commission for studying the amount of ergot to be permitted in oats, Bastide et al. (*Bul. Off. Gouvt. Gén. Algérie, 1907, No. 13, Sup., pp. 176–258, charts 19*).—It appears that ergot is so commonly found in oats as offered upon the market in Algeria that a commission was established to determine the percentage of ergot which could be present in oats considered merchantable according to the law. The committee organized and carried out two sets of experiments in feeding known quantities of ergot to 10 healthy horses.

In the first set of experiments 2.5 gm. of ergot were added daily to 5 kg. of healthy oats and fed to the horses. The effect of feeding this amount of ergot daily for 6 weeks was not marked in any of the horses in respect to weight, temperature, heart beat, or respiratory action. The committee were unanimously agreed on the fact that no effects were observed that could be definitely attributed to ergot.

Another set of experiments was carried out during which the horses received from 2.5 to 5 gm. of ergot daily. The results in this case were likewise of a negative character, and it appears that the quantity of ergot normally found in oats can scarcely be considered a serious matter.

Means of protecting veterinarians in the examination of glanderous horses, A. I. Spasski (*Arch. Vet. Nauk [St. Petersb.], 37 (1907), No. 4, pp. 324, 325*).—A brief description is given of a mask to be worn over the face and of other apparatus to be worn on the hands in order to protect the observer from possible infection with glanders during the examination of horses.

Septicemia hemorrhagica in mules, E. C. Webb (*Jour. Compar. Path. and Ther., 20 (1907), No. 2, pp. 97–100*).—Occasion was had to study a number of serious cases of disease in mules in India. The post-mortem lesions were those of acute septicemia and cultures almost pure were obtained of the organism of hemorrhagic septicemia from diseased horses and mules. It is believed, therefore, that these cases were instances of true hemorrhagic septicemia. This disease has heretofore been considered rare in both horses and mules.

Biliary fever in dogs, D. Hutcheon (*Agr. Jour. Cape Good Hope, 30 (1907), No. 6, pp. 764–774*).—A general historical account is presented of the investigation of this disease in South Africa. It has been shown conclusively that it is carried by *Hæmophysalis leachi* and that the blood parasite which causes it is *Piroplasma canis*. The symptoms and post-mortem findings are briefly discussed. A preventive vaccine has not been devised. Some benefit is derived from the administration of calomel and quinin to diseased dogs, and infestation by ticks may be to some extent prevented by treating the dogs' legs with oily substances which may repel the ticks.

Leucocytozon canis, S. R. Christophers (*Sci. Mem. Med. and San. Depts. India, n. ser., 1906, No. 26, pp. 16, pl. 1; 1907, No. 28, pp. 12, pl. 1*).—*Leucocytozoon canis* belongs to the hemogregarines and reproduces itself by the formation of true cysts containing each about 30 sporozoits. Encystment takes place in the cells of the bone marrow. After escaping from the cysts the sporozoits invade the mononuclear cells in the marrow. The parasite is essentially one of the bone marrow. It is probably carried by the dog tick, flea, mosquito, or some species of Hippobosca. In fact the development of the parasite has been followed by the author in the body of *Rhipicephalus sanguineus*.

A parasite found in the white corpuscles of the blood of palm squirrels, W. S. Patton (*Sci. Mem. Med. and Sanit. Depts, India, n. ser., 1906, No. 24, pp. 13, pl. 1*).—Hemogregarines of the type studied by the author were previously known only as parasites of cold-blooded animals. The species studied by the author is described as new under the name *Leucocytozoon funambuli* and is parasitic in the blood of *Funambulus pennantii*. The parasite is found in the body of a louse belonging to the genus Hematopinus commonly observed on the squirrel.

Note on the occurrence of flagellated organisms in the liver of the pigeon, W. Jowett (*Jour. Compar. Path. and Ther., 20 (1907), No. 2, pp. 122–125, figs.*

2.)—The liver in badly diseased pigeons exhibited swellings over its surface which contained peculiar nucleated bodies furnished with 1 or 2 flagella. Occasionally these organisms showed the presence of vacuoles. The author refers the organism to the genus Cercomonas.

Live stock and complete stock doctor. A cyclopedia, J. Periam and A. H. Baker (*St. Louis, 1907, pp. 1298, pls. 30, figs. 946, charts 2*).—The present volume includes a general popular account of the history, management, breeds, feeding, and diseases of horses, cattle, sheep, swine, goats, and poultry, together with a brief chapter on bee raising. A considerable number of the illustrations used in the volume were taken from prize animals at the Louisiana Purchase Exposition.

The modern abattoir; construction, installation, and administration, A. Moreau (*L'Abattoir Moderne; Construction, Installation, Administration. Paris, 1906, pp. XVI+477, figs. 90*).—In this volume particular attention is given to an account of the construction, installation, and management of abattoirs in France. It is maintained that too little attention has been given to the technique of construction in these abattoirs, a majority being modeled upon that at the Villette market. By way of comparison the structural details of abattoirs in other European countries are also considered.

Attention is also given to arrangements for slaughtering various animals, cold storage, accessory industries connected with abattoirs, sanitary management of abattoirs, and veterinary inspection of premises and animals.

Farm hygiene, P. Regnard and P. Portier (*Hygiène de la Ferme. Paris, 1906, pp. XII+477, figs. 171*).—The practical matters relating to hygiene of farm buildings, barnyards, water supply, feeding stuffs, and premises are discussed in considerable detail. The larger part of the volume is occupied with an account of infectious diseases of farm animals and practical methods by which these diseases may be held in check or prevented from occurring.

RURAL ENGINEERING.

Irrigation in northern Italy, II, E. Mead (*U. S. Dept. Agr., Office Expt. Stas. Bul. 190, pp. 86, pls. 4, figs. 2*).—This bulletin is the second part of the report of the observations on irrigation in Italy made by Doctor Mead in the summer of 1903, and deals with the section watered by the Adda and Adige rivers, taking up especially the legal and institutional phases of irrigation and describing the operation of canals controlled by the Government and those controlled by cooperative associations of water users.

The history and present status of the irrigation laws of Italy are given, with some comparisons with American conditions. The development of irrigation laws from the early Roman law to the present time is sketched and a statement of the present law, enacted in 1884, is given. The unification of Italy as a kingdom made the National Government the successor to all the water rights which had hitherto belonged to the separate provinces, and one of its first acts was the declaration of the public ownership of all unappropriated public waters. This was followed by the enactment of a law providing for the determination of what are public waters and the compiling of a list of all rights to these waters, and making provision for the acquiring of rights in the future by grant only.

Concessions are now granted either by a law of the Kingdom or by an administrative decree, and are always made subject to existing rights. As a rule they are limited to thirty years, but perpetual rights may be granted by a law of the Kingdom. While the law makes the nation supreme in matters relating to the granting of rights for irrigation, it entrusts the exercise of this authority to local officials in the granting of rights of only local interest. This division of power has not, however, been satisfactory, at least to the officials of the General Government, and a commission was appointed in 1898 to recommend changes in the existing law. This report shows that the reason assigned for the appointment of the commission was the claim that the provincial officials were not exercising the proper care in the granting of rights, especially for the development of power, but were allowing power rights to get into the hands of foreign capitalists, who were establishing a monopoly for the exploitation of the real users of water. The proposed cure for this threatened monopoly of natural resources was to give exclusive authority to grant such rights to the General Government. This commission recommended the creation by law of a permanent board to which all such applications should be referred. No such law has been enacted, but a commission formed on the lines recommended has been created by royal decree, which, however, acts in an advisory capacity only.

The Kingdom of Italy charges for water diverted from public streams, the amount of the charges being fixed by law. The charges for water for drinking and for irrigation without the obligation to return the waste water to the stream is $2.83 per cubic foot per second per year, while the charge for the same quantity with the obligation to return the waste water is but one-half as great. Where it is impracticable to measure the water diverted the charge is 40 cts. per acre irrigated. The place of use of the water is not limited, the lessee having the right to use the water or to sublet without limit on the prices.

In addition to controlling the streams the Government owns certain canals which are leased as a whole, and other canals which are operated by the Government with leases to associations of water users or to individuals.

Further aid to irrigation is given by the Government contributing to the cost of construction of works built by associations or individuals. This aid is conditioned upon contributions by the provinces and communes where the works are situated, these local contributions being not less than one-tenth of the sum granted by the Government. The aid given by the kingdom is a part payment of the interest on money borrowed to carry out the work. The total contribution is usually 3 per cent of the estimated cost of the work annually for the first ten years, 2 per cent per year for a second period of ten years, and 1 per cent per year for a third period of ten years. This aid may be given to enlarge or complete works as well as for new works.

The Government further aids irrigation by granting loans from State banks. The procedure for making these loans, the amount of interest to be charged, and the security to be demanded are all fixed by the minister of finance. The maximum period of loans is ten years, except where a sinking fund is provided, when the maximum period is 25 years.

Associations for the construction of irrigation works through government aid are provided for by law. The associations may be either voluntary or obligatory. Obligatory associations are organized by the courts on the application of a majority of those interested and are in fact similar to irrigation districts or drainage districts in this country.

The report describes the operation of a typical government canal and of two association canals, illustrating the operation of these laws.

Irrigation and drainage laws of Italy, R. P. Teele (*U. S. Dept. Agr., Office Expt. Stas. Bul. 192, pp. 100*).—This bulletin gives the texts of laws which govern the securing of rights to divert public water, the organization of the associations for irrigation similar to our own irrigation districts, and government aid to irrigation. It includes all the drainage laws except special acts relating to individual projects. The regulations for the carrying out of these laws are also given.

Excavating machinery used for digging ditches and building levees, J. O. Wright (*U. S. Dept. Agr. Office Expt. Stas. Bul. 191, pp. 89, pls. 20, figs. 13.*—various types of excavating machinery used for digging ditches and building levees are described, and the conditions to which each is adapted are discussed, together with some general observations on ditching operations.

The only feasible way in which large areas of swamp land can be drained is stated to be by the use of a dredge. The cost ranges from 3 cts. per cubic yard up, according to the kind of dredge, the character of the work, and the efficiency of the management.

"Where there is much water on the surface or many trees and stumps to be removed, a floating dipper dredge is the best for work," while "for small ditches on firm ground some kind of traction machine is preferable. . . . A 1-yd. or 1½-yd. dredge seems to be best suited for ordinary drainage work.

"A floating dredge should commence at the upper end of the ditch and work down stream, and a traction dredge at the lower end and work up stream. When constructing large ditches having water flowing in them the greater part of the year, the slope of the bank is not of much importance, as nature will soon make the slope best suited to the soil. In small ditches, with water flowing only a part of the time, smooth, sloping banks and a true grade are very essential. . . .

"If a dredge is properly designed, well built, and suited to the work to be done, it is an efficient and cheap appliance for digging ditches or building levees." A clam-shell dredge with a long boom is well suited for the latter purpose.

"A machine can now be had which will dig from 70 to 100 rods of tile ditch 30 to 36 in. deep in a day of 10 hours at a cost of operation not exceeding $10 per day."

Tests of internal-combustion engines on alcohol fuel, C. E. Lucke and S. M. Woodward (*U. S. Dept. Agr., Office Expt. Stas. Bul. 191, pp. 89, pls. 20, figs. 13*).—This is a technical report giving the results of tests carried out for the Office of Experiment Stations in the mechanical engineering laboratories of Columbia University.

Eight different kinds of gasoline and kerosene engines of American manufacture were run on alcohol fuel as well as upon the fuels for which they were originally constructed, and careful observations were made of fuel consumption, power developed, and general behavior of the engines under different conditions of operation. Of these five were different slow-speed engines varying from 6 to 15 horsepower, and three high-speed engines, of which two were automobile engines and one a 2-cycle marine engine. The results of 192 consumption tests are given in detail, as well as many observations of a qualitative nature, and full discussions of the results are included.

The following general conclusions are drawn:

"(1) Any gasoline engine of the ordinary type can be run on alcohol fuel without any material change in the construction of the engine. The only difficulties likely to be encountered are in starting and in supplying a sufficient quantity of fuel, a quantity which must be considerably greater than the quantity of gasoline required.

"(2) When an engine is run on alcohol its operation is more noiseless than when run on gasoline, its maximum power is usually materially higher than it is on gasoline, and there is no danger of any injurious hammering with alcohol such as may occur with gasoline.

"(3) For automobile air-cooled engines alcohol seems to be especially adapted as a fuel, since the temperature of the engine cylinder may rise much higher before auto-ignition takes place than is possible with gasoline fuel; and if auto-ignition of the alcohol fuel does occur no injurious hammering can result.

"(4) The consumption of fuel in pounds per brake horsepower, whether the fuel is gasoline or alcohol, depends chiefly upon the horsepower at which the engine is being run and upon the setting of the fuel supply valve. It is easily possible for the fuel consumption per horsepower hour to be increased to double the best value, either by running the engine on a load below its full power or by a poor setting of the fuel supply valve.

"(5) These investigations also showed that the fuel consumption was affected by the time of ignition, by the speed, and by the initial compression of the fuel charge. No tests were made to determine the maximum possible change in fuel consumption that could be produced by changing the time of ignition, but when near the best fuel consumption it was shown to be important to have an early ignition. So far as tested the alcohol fuel consumption was better at low than at high speeds. So far as investigated, increasing the initial compression from 70 to 125 lbs. produced only a very slight improvement in the consumption of alcohol.

"(6) It is probable that for any given engine the fuel consumption is also affected by the quantity and temperature of cooling water used and the nature of the cooling system, by the type of ignition apparatus, by the quantity and quality of lubricating oil, by the temperature and humidity of the atmosphere, and by the initial temperature of the fuel.

"(7) It seems probable that all well-constructed engines of the same size will have approximately the same fuel consumption when working under the most advantageous conditions.

"(8) With any good small stationary engine as small a fuel consumption as 0.70 lb. of gasoline, or 1.16 lb. of alcohol per brake horsepower hour may reasonably be expected under favorable conditions. These values correspond to 0.118 and 0.170 gal. respectively, or 0.95 pint of gasoline and 1.36 pints of alcohol. Based on the high calorific values of 21,120 British thermal units per pound of gasoline and 11,880 per pound of alcohol, these consumptions represent thermal efficiencies of 17.2 per cent for gasoline and 18.5 per cent for alcohol.

"But calculated on the basis of the low calorific values of 19,660 British thermal units per pound for gasoline and 10,620 for alcohol, the thermal efficiencies become 18.5 for the former fuel and 20.7 for alcohol. The ratio of the high calorific values used above is, gasoline to alcohol, 1.78. The corresponding ratio of the low calorific values is 1.85. The ratio of the consumptions mentioned above is, alcohol to gasoline, 1.66 by weight, or 1.44 by volume."

Comparative values of alcohol and gasoline for light and power, J. B. DAVIDSON and M. L. KING (*Iowa Sta. Bul. 93, pp. 24, figs. 12*).—The investigations of which those here reported form a part were undertaken "for the purpose of making a comparison between (1) the heat value of the fuels, (2) their economy in the production of light, (3) their economy in the production of power, and (4) the relative safety of alcohol and gasoline for general use."

Studies of illuminating power were made with 3 forms of gravity lamps, a wick gasoline lamp, a pressure over-head generator lamp, and an ordinary kerosene lamp. The tests of power production were made with 3 different makes of gasoline engines having ordinary compression pressures. It was found impossible to secure an engine especially designed for alcohol, "and it was further found practically impossible to properly alter the design of any of the larger gasoline engines found in the laboratory for the most advantageous use of alcohol."

The results obtained are summarized as follows:

"(1) The higher heat value of 94 per cent alcohol is but 68 to 71 per cent that of gasoline.

"(2) The lower heat value (the value more nearly attained in practice) of 94 per cent alcohol is but 66 per cent to 69 per cent that of gasoline.

"(3) When used for the production of light, 94 per cent alcohol will produce from 53 per cent to 85 per cent as much light as an equal volume of gasoline

"(4) Alcohol of 94 per cent purity must be sold for from 11 to 17 cts. per gallon to compete with gasoline for lighting purposes at 20 cts. per gallon (the present retail price of gasoline in Ames).

"(5) Alcohol, when used in a generator lamp, will produce from two to four times as many candle power hours as kerosene in a wick lamp.

"(6) It was found impossible to soot the mantels of any of the lamps with alcohol.

"(7) Alcohol of 94 per cent purity, when used in engines designed for gasoline, has but 68 per cent to 85 per cent the value of gasoline in the production of power.

"(8) To compete with gasoline at 20 cts. per gallon for use in gasoline engines, 94 per cent alcohol must be sold for from 13 to 17 cts. per gallon and 90 per cent alcohol from 11 to 15 cts. per gallon.

"(9) None of the engines could be started readily with alcohol, although a few could be started with less difficulty than others.

"(10) After having once been started with gasoline and warmed up, the carburetors as designed for gasoline vaporized the alcohol successfully, except in once instance.

"(11) No doubt the gasoline carburetor can be readily changed to permit the use of alcohol as well as gasoline in the same engine.

"(12) Experimental work does not include tests of the special designed alcohol engine which should show better economy in the use of alcohol.

"(13) Gasoline can not be used readily in a special designed alcohol engine using high compression on account of pre-ignition.

"(14) The odor of the exhaust of an engine when using alcohol is not as unpleasant as when using gasoline.

"(15) Alcohol is much more pleasant to handle.

"(16) There is much less danger from fire when using alcohol than when using gasoline, owing to the fact that alcohol does not vaporize as readily as gasoline and its flame may be extinguished with water.'"

Public-road mileage, revenues, and expenditures in the United States in 1904, M. O. ELDREDGE (*U. S. Dept. Agr., Office Pub. Roads, Bul. 32, pp. 100, figs. 2*).—This bulletin consists largely of data already reported for each State in Circulars 39–46 and 48–87 of the Office of Public Roads, but the results of the whole investigation are assembled for a more convenient study and discussion, "in order that such comparisons and deductions may be made as will aid the public in locating defects in our present systems of road management."

"In 1904 there were 2,151,570 miles of public road in the United States. Of this mileage, 108,232.9 miles were surfaced with gravel, 38,621.7 miles with stone, and 6,809.7 miles with special materials, such as shells, sand-clay, oil, and brick, making in all 153,664.3 miles of improved road. From this it follows that 7.14 per cent of all the roads in this country have been improved."

The total expenditures during 1904 amounted to $79,771,417.87. This is $37.07 per mile of public road, or $1.05 per capita.

RURAL ECONOMICS.

The present status of the international cooperative movement in agriculture, Paisant (*Rev. Gén. Agron., n. ser., 2 (1907), Nos. 4, pp. 183, 184; 5, pp. 235–237*).—Brief accounts are given of the International Agricultural Association for establishing the price of cereals, the International Institute of Agriculture, and the International League of Agricultural Cooperative Societies, a new society organized in January, 1907.

The organization, constitution, and aims of these different bodies are briefly discussed. Their purpose in general is to secure and disseminate information regarding the specific branches of agriculture in which each international body is interested and to secure greater returns to the producers of agricultural forms of wealth.

[Report on the mutual agricultural insurance societies in France] (*Bul. Mens. Off. Renseig. Agr. [Paris], 6 (1907), Nos. 6, pp. 676–689; 7, pp. 787–794*).—This is the report of the minister of agriculture for 1906, and gives data to May 1, 1907.

The total number of mutual insurance societies in France on that date was 7,824. Of this number 6,730 were societies for insuring against loss of live stock, with 355,600 members carrying insurance on stock valued at 384,895,435 francs; 1,008 insured against loss from fire with 34,457 members carrying insurance on property valued at 291,334,850 francs, and 28 insured against loss from hail with 42,550 members carrying insurance on growing crops valued at 27,749,815 francs. Statistics are also presented of 58 other mutual insurance societies.

Agricultural warrants, R. Worms (*Bul. Soc. Nat. Agr. France, 67 (1907), No. 5, pp. 438–449*).—The author discusses the operation of the law of July 18, 1898, legalizing the issuance of warrants for the securing of credit on agricultural products, implements, etc., and points out the beneficial features of the new law of April 30, 1906. Statistics show that from July 1, 1901, to December 31, 1903, there were issued 4,658 warrants securing loans of 15,293,036 francs, largely on crops. It is believed that, under the more favorable provisions of the new law, the farmers of France will continue in increasing numbers to use this form of obtaining credit.

The agricultural warrant according to the French law of April 30, 1906, H. L. Rudloff (*Fühling's Landw. Ztg., 56 (1907), No. 15, pp. 519–528*).—The author discusses the present law, compares its provisions with those of the law of 1898, and points out where improvement can still be instituted. While granting that the law of 1906 indicates a positive advance in behalf of the tenant farmer, the author believes it is not the final word on agricultural warrants, which are capable of further development along social, economic, and legal lines, particularly as regards the rights of lessors of farms.

Concerning credit for agricultural improvements, E. Cinquini (*Bol. Quind. Soc. Agr. Ital., 12 (1907), No. 16, pp. 743–747*).—The author discusses sections of the law of December 22, 1905, relating to the agricultural credit fund, shows how the operation of the provisions of the law relating to repayment is liable to embarrass rather than to aid the farmer who borrows to improve his property or to increase the production of crops, and makes suggestions as to wherein the law can be improved.

The improvement suggested consists in providing easier financial facilities and methods of procedure in the formation of societies relating to agriculture, and that the government itself supervise such funds in order to diminish the risk of loss and increase the likelihood of gain on the part of those who adopt this means of securing credit.

The real condition of cooperation in Germany, H. Crueger (*Rev. Econ. Internat., 3 (1907), No. 2, pp. 272–303*).—The author discusses the progress of the cooperative movement in Germany, with statistical data regarding the number and kind of societies, membership, value of products, extent of credit, etc., to the close of 1905. Agriculture is said to hold the most important place in the development of cooperation, to have overcome the greatest economic difficulties, and to have brought about great improvement in the condition of production.

The significance of agricultural cooperative societies in Germany, Grabein (*Ztschr. Agrarpolitik, 5 (1907), No. 6, pp. 234–246*).—The author shows that on May 1, 1907, there were 20,845 agricultural cooperative organizations in Germany and discusses the advantages of this movement in promoting the economic welfare of small farmers.

The progress of agricultural cooperation in Tunis (*Quinz. Colon., 11 (1907), No. 14, pp. 585–587*).—Two years ago mutual credit and agricultural cooperative societies were unknown in Tunis, but in 1907 there were 19 credit societies which had advanced to members on personal credit sums amounting to about 800,000 francs. Cooperative societies for the purchase of agricultural supplies and the sale of agricultural products were not instituted until 1906, but their progress is said to have been as remarkable as that of the credit societies.

[Yearbook of world economics, 1905 and 1906], R. Calwer (*Das Wirtschaftsjahr. Jena, 1906, pp. XXVI+347; 1907, pp. VII+341*).—These volumes for the years 1905 and 1906 give statistical data with discussions relating to labor, agriculture, mining, iron and textile manufactures, finance, etc., in comparison with similar data for preceding years.

The statistics on agriculture relate principally to the acreage, yields, prices, and exports and imports of wheat, rye, barley, oats, corn, and potatoes. In comparison with 1905, the data show in general an increase in 1906.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 9 (1907), No. 11, pp. 81–88*).—The usual statistical data on the condition, production, value, and prices of agricultural products in the United States and foreign countries are summarized and discussed.

Census of manufactures, 1905. Agricultural implements (*Bur. of the Census [U. S.] Bul. 75, pp. 31, dgms. 2, maps 2*).—This bulletin gives detailed statistics with discussion of the manufacture of agricultural machinery for more than half a century, and includes data on the number and value of implements used for tilling the soil, sowing or planting the seed, harvesting, and preparing crops for the market.

The value of farm implements and machinery in use on the farms of the United States in 1904 was $844,989,863, a gain of nearly $100,000,000 since 1900. In addition a large proportion of the labor-saving agricultural implements and machinery in use on farms in all parts of the world was of American manufacture. The value of agricultural implements manufactured in 1905 was $112,007,344, of which $20,721,741 worth was exported as compared with $22,749,635 worth exported in 1904.

[Agricultural statistics of Nebraska], J. J. Ryder (*Nebr. Bur. Labor and Indus. Statis. Bul. 11, pp. 26*).—Detailed statistical data on the acreage under crops and in orchards in 1907, and on the shipment of surplus agricultural commodities in 1906, including live stock, cereals, hay, and dairy, poultry, and miscellaneous products. The total value of shipments in 1906 was $186,303,454, a gain of $35,750,104 over the preceding year.

Agricultural statistics, 1906, R. H. Rew (*Bd. Agr. and Fisheries [London], Agr. Statis., 41 (1906), Nos. 3, pp. 167–333, dgms. 9; 4, pp. 335–443*).—Part 3 gives detailed statistics on the prices of agricultural products, supplies of live stock at markets, and the imports and exports of agricultural commodities for the year 1906. The imports of staple food products showed a slight gain per capita over preceding years.

The quantities of principal food products imported in 1906 were per head of population: Wheat 239 lbs., flour 36 lbs., potatoes 10 lbs., meat 47.3 lbs., butter and margarine 13.9 lbs., cheese 6.8 lbs., and eggs 52. The total number of eggs imported in 1906 was 2,264,887,000. It is claimed that the statistics show a growing dependence of the population upon supplies from abroad, but that the British colonies are in general gradually displacing foreign competition.

Part 4 gives detailed statistics of the acreage and yields of crops and number of live stock in the British Empire and foreign countries for 1906 in comparison with similar data for the two preceding years. The prices of agricultural produce in the chief colonial and foreign markets are included.

Report on agriculture for the Province of New Brunswick for the year 1906, L. P. FARRIS (*Rpt. Agr. New Brunswick, 1906, pp. 312+IV*).—The acreage and yields of crops and the output of dairy products for the year 1906 are reported and discussed. The papers and addresses on agricultural topics delivered at the sixth annual maritime winter fair, together with reports of the proceedings of the agricultural societies of the province, are included.

The economic relations of agriculture in North Schleswig, H. BACHMANN (*Landw. Jahrb., 36 (1907), No. 3, pp. 425–471*).—The author gives data derived from 16 farms ranging from 28 to 101 hectares (69.2 to 249.5 acres) in size and from 1 farm of 230 hectares (568.1 acres) as to the quantity of land under cultivation, the percentages of different crops grown, and the amount of capital invested which is differentiated and discussed under the titles of land, buildings, live stock, implements, and circulating capital, the percentage relations of the value of each form of capital to the others being pointed out. He also presents statistics on the cost of production and returns on investment and labor. In the latter case comparisons between the wages of hired labor and the members of the family, individually and collectively, are made.

Natal agricultural statistics [for 1906] (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 7, pp. 772–777*).—Tabulated data on the results of European farming in the colony including the acreage and yields of crops, the number of agricultural implements, machinery, accessories, and live stock owned by Europeans, the nature, quantity, and value of animal products, and the number, kind, and wages of farm laborers are reported.

AGRICULTURAL EDUCATION.

Report of committee on extension work, 1906–7 (*U. S. Dept. Agr., Office Expt. Stas. Circ. 75, pp. 16*).—This is the second report of the committee on extension work of the Association of American Agricultural Colleges and Experiment Stations. It embodies a compilation of information secured from 46 of the land-grant institutions concerning the extension work already undertaken by them, and recommendations by the committee that each of the colleges represented in the association organize as soon as practicable a department of extension teaching in agriculture, or, in case this is at present impracticable, that they appoint in each case a faculty committee to carry on this work.

The farmer's debt to science, F. W. BICKNELL (*Amer. Mo. Rev. of Reviews, 36 (1907), No. 2, pp. 186–194, figs. 10*).—This is a discussion of the short courses, extension work, county experiment stations, animal husbandry work, and domestic science teaching of the Iowa State College of Agriculture and Mechanic Arts.

Agricultural and industrial schools in Iowa, W. LOUDEN (*1907, pp. 23*).—This is an address before the Iowa manufacturers' meeting at Council Bluffs, June 7, 1907, in which the importance of the agricultural college to the farmer is dwelt upon.

Educating boys to be farmers, W. J. SPILLMAN (*Farm and Ranch, 26 (1907), No. 37, pp. 4, 5*).—An epitome of an address delivered at the Texas Farmers' Congress in July, 1907, in which the speaker notes examples of success in farming which he attributes to education and good management, and brings the American public school system to task for affording very little training which encourages boys to live in the country. He cites the agricultural colleges and the few agricultural schools as exceptions, but shows that in Texas, for example, if the State agricultural college were to attempt to provide a graduate for each of the 352,000 farms in the State once in 25 years, it would have to graduate 14,000 men from its agricultural course every year. This being manifestly impossible, he advocates the establishment of agricultural high schools with a little more practical work than is provided in the curricula of the agricultural high schools in Georgia. He would have four commercial establishments connected with each high school—a dairy farm of about 60 acres, an orchard and truck farm, a large poultry plant, and a general farm, all run as commercial enterprises, the work to be done entirely by the students in the high school during the first two years of their course, under the immediate supervision of trained instructors.

"At the end of these two years a boy should know how to milk a cow better than any farmer in Texas knows to-day; he should know how to prune a tree, and how to pack a box of fruit for shipment. During the third year the practical work of the high school student is that of the instructor of the first and second year students. During this year the student learns how to manage others—one of the most important things that a young man has to learn. During the fourth year the student should make working plans for every one of these four industries, and for a part of the year he should be the actual superintendent of each of them in turn."

The Macdonald movement for rural education. Evidence of J. W. Robertson before the select standing committee on agriculture and colonization, 1906–7 (*Ottawa, 1907, pp. 183–206, pls. 4, maps 2*).—Information concerning the Macdonald movement for rural education which was brought out in hearings before a select standing committee on agriculture and colonization, including statements concerning benefits to agriculture resulting from agricultural education and the educational institutions developed as a part of this movement, among which are manual training centers, school gardens, consolidated rural schools, the Macdonald Institute at Guelph, and Macdonald College at Ste. Anne de Bellevue.

Agricultural education, W. C. PALMER (*Ind. Farmer, 62 (1907), No. 32, p. 1, fig. 1*).—An appeal for the teaching of agriculture in the public schools and for the establishment of practical agricultural schools.

Agriculture in the common schools, J. G. HERRON (*Ann. Rpt. Ohio Bd. Agr., 61 (1907), pp. 180–184*).—This is a farmers' institute address in which some of the reasons for the movement of country people to the city are set forth, among these the influence of schools. The teaching of agriculture in the common schools is mentioned as one of the possible remedies for this condition, but it is pointed out that before this can be successfully accomplished the schools need to be improved in other ways.

Agriculture in the country schools, W. G. MILLER (*Ann. Rpt. Ohio Bd. Agr., 61 (1907), pp. 177–180*).—This is an address before a farmers' institute in which it is argued that country boys should receive some instruction in agriculture, which is regarded as the most important branch of industry. The purpose of such instruction is said to be twofold—to help meet the wants of the times by giving the boy an agricultural education and to keep him on the farm; but whether the boy stays on the farm or not, agriculture should be taught in order that he may be brought into touch with nature in all of her phases and may know something of this great industry upon which all trades and professions depend.

The Swiss horticultural school for women, L. HENRY (*Rev. Hort. [Paris], 79 (1907), No. 13, pp. 305–308, figs. 2*).—This is a description of the first Swiss horticultural school for women, which is located at Niederlenz, near Lenzbourg, in the canton of Argovie. The buildings and grounds are described and some account is given of the work of the institution.

Teaching of cookery to public elementary school children in England and Wales; special report by the chief woman inspector of the Board of Education, M. A. LAWRENCE (*London Bd. Ed., 1907, pp. 36*).—This is the first special report issued by the Board of Education upon the work of the various training schools for teachers of cookery and upon instruction in cookery actually given to children in the public elementary schools. In a prefatory memorandum a summary is given showing the regulations governing instruction in this subject and describing the work of training schools in domestic subjects. The report proper deals with the work actually being done in the different centers.

Nature study teaching, P. H. ARCH (*Agr. Econ., 40 (1907), No. 453, pp. 260, 261, figs. 2*).—A description of the exhibition of rural school work in nature study, gardening, agriculture, rural handicrafts, and literature at the royal agricultural show at Lincoln.

Suggestions for grain-growing contests, score cards, and rules for judging wheat, oats, and corn, C. P. BULL (*Univ. Minn., Dept. Agr., Rural School Agr. Bul. 2, rev., pp. 116, figs. 38*).—This is a revision of Rural School Agriculture Bulletin No. 2 (E. S. R., 17, p. 715) with the addition of data concerning barley, sewing, cooking, and vegetable and fruit growing.

Report of curator of school gardens, LOUISE K. MILLER (*Ann. Rpt. Bd. Ed. Cleveland Pub. Schools, 70 (1906), pp. 65–69, pls. 3*).—A report on the supervision of school gardens, improvement of school grounds, the propagating center at Rosedale School, exchange gardens, and lectures on gardening in the Cleveland public schools.

Syllabus of illustrated lecture on roads and road building (*U. S. Dept. Agr., Office Expt. Stas. Farmers' Inst. Lecture 7, pp. 16*).—The topics considered in this lecture, prepared by the Office of Public Roads of this Department, are methods of construction, location, drainage, earth roads, sand-clay roads, burnt-clay roads, dust preventives, hard roads, and road administration. An appendix includes a list of 41 lantern slides, designed to illustrate the lecture, a list of references to publications bearing on the subject, and a table showing the mileage and expenditures for public roads by States during 1904.

MISCELLANEOUS.

Sixteenth, Seventeenth, and Eighteenth Annual Reports of Delaware Station, 1904–1906 (*Delaware Sta. Rpts. 1904–1906, pp. 115*).—This contains a financial statement for the years ended June 30, 1904, 1905, and 1906, the organization list and reports of the chemist, horticulturist, assistant mycologist, and bacteriologist. The report of the chemist includes analyses of pigeon manure, cowpeas, corn, millet, clover hay, and marl. The remaining portions of these reports noting experimental work other than that previously reported in bulletin form, are abstracted elsewhere in this issue.

Annual Report of Hawaii Station, 1906 (*Hawaii Sta. Rpt. 1906, pp. 88*).—This consists of a general review of the work of the station during the year, reports of the entomologist and horticulturist, and papers on organic nitrogen in Hawaiian soils, and the economic seaweeds of Hawaii and their food value. These papers and most of the experimental data included in the reports are abstracted elsewhere in this issue.

Annual Report of Nevada Station, 1906 (*Nevada Sta. Rpt. 1906, pp. 31*).—This contains reports of the board of control, the director, and heads of departments. The director discusses the Adams Act and the work undertaken under it, and gives a list of the publications of the year, and a financial statement for the fiscal year ended June 30, 1906. The departmental reports contain notes on the work in chemistry, botany, horticulture and forestry, zoology and bacteriology, agriculture and animal husbandry, and entomology. The experimental work in agronomy is abstracted elsewhere in this issue.

Contents of and index to bulletins of the Bureau of Plant Industry Nos. 1–100, inclusive, J. E. Rockwell (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 101, pp. 102*).—This contains a brief introductory statement as to the various publications of the Bureau and the form of distribution, a list with tables of contents of Bulletins 1–100, inclusive, and an index to these bulletins.

Index to Farmers' Bulletins 1–250, C. H. Greathouse (*U. S. Dept. Agr., Div. Pubs. Bul. 8, pp. 148*).

[Report on agriculture in Fiji, 1906] (*Leg. Council Fiji Paper No. 13, pp. 16*).—A brief account is given of work carried on during the year at two experiment stations in Fiji, including trials of various crops and studies of insect pests and plant diseases, and of fertilizer experiments conducted on a number of estates, with analyses of the soils of one of the stations and meteorological records kept at Suva.

NOTES.

Alabama College and Station.—The resignation of A. J. Norman, assistant in horticulture, to engage in commercial orchard work in Nebraska, has been followed by the appointment of Percy F. Williams, a graduate of the Massachusetts College, to fill the vacancy.

Colorado College and Station.—George P. Weldon, assistant entomologist at the Maryland Station, has been appointed field assistant of the fruit investigations at Delta, vice E. P. Taylor, resigned to accept a position as entomologist with the Missouri Fruit Station. The college is to erect a two-story brick building 60 by 120 ft. for civil and irrigation engineering. The cooperative work in horse breeding has been reorganized under a new arrangement whereby both the station and this Department will devote an increased amount of funds to the project.

Connecticut State Station.—H. R. Stevens, a graduate of the University of Vermont, and K. G. Mackenzie, a graduate of Yale University, have recently joined the station staff as chemists.

Georgia College.—A cotton school for farmers was held January 6–17, which is believed to be the first of its kind. Lectures were given on the soil, fertilizers, the cotton plant, seed selection, cotton diseases and insect pests, feeding cotton by-products, and cotton machinery, together with practical instruction in cotton grading, cotton warehousing, and the handling of cotton seed. About 120 farmers were in attendance.

Substantial progress is being made in the erection of the new agricultural building. A dairy barn has been recently completed, and a barn is now under construction for the department of field experiments.

Hawaii College.—J. E. Roadhouse, of this Office, whose appointment as dean was recently noted, died November 28, 1907. W. T. Pope, a graduate of the Kansas College and head of the science department of the Honolulu Normal School since 1902, has been appointed acting dean, and will proceed with the inauguration of the institution and the organization of its work. It is now hoped to begin actual instruction February 1.

Idaho University and Station.—R. E. Hyslop, late of the Wyoming University and Station, has been appointed agronomist.

Purdue University.—The third State corn show and the first State fruit show were held on the university grounds in connection with the farmers' short course, January 13–18, through the cooperation of the respective State organizations with the university.

Iowa College and Station.—Recent appointments include C. A. Scott, of the Forest Service of this Department, to succeed H. P. Baker; J. F. Barker, a recent graduate of the Ohio University, vice E. B. Watson, who has accepted a position with the Bureau of Soils; and S. S. Fay, of the Ohio Station, who has been elected to the position of experimentalist in the division of soils.

Kansas College and Station.—*Industrialist* announces the appointment of J. C. Kendall, recently State dairy commissioner, as head of the department of dairy husbandry, and of D. M. Wilson, assistant in dairy husbandry, as dairy commissioner. December 14 was observed in the State as alfalfa day, over 250 meetings being held for the discussion of this topic. The annual farmers' institute at the college was held December 26 to January 4, with courses in judging corn, live stock and poultry, dairy testing, cooking, and sewing. The various State breeders' associations held meetings in connection with the institute. A novel feature was the boys' corn judging contest, participated in by about 400 boys who were the winners of local contests and were receiving the trip to the college as a prize.

Louisiana Stations.—B. W. Edgerton, of Cornell University, has been appointed plant pathologist to begin work February 1. H. P. Agee has been given leave of absence and will spend the sugar season in Porto Rico.

Maine Station.—G. M. Gowell has resigned from the station work, his resignation becoming effective January 1. The work in poultry breeding is to be continued by the station biologists.

Massachusetts Station.—E. Thorndike Ladd, first assistant chemist in the fertilizer division, has resigned to engage in commercial work, and has been succeeded by Philip V. Goldsmith, a graduate of the Michigan College. James C. Reed, a graduate of the University of Vermont, has been appointed second assistant chemist.

Michigan College and Station.—Plans have been completed for the new agricultural building to be erected on the former site of the barns, at a cost of approximately $125,000. The insectary has been completed and will be used for investigations in entomology, soil chemistry, and botany. An investigation of the so-called Grand Traverse disease of cattle, which was widely prevalent in the northwestern part of the Lower Peninsula, has resulted in the discovery that the continued anæmia usually resulting in starvation was due to a chronic impaction of the third stomach. The remedies worked out by the station have proved efficient in every case where applied before the animal was unable to stand, and the investigation has been concluded for the present.

Missouri University.—Dr. Albert Ross Hill, formerly dean of the College for Teachers of the University, and at present dean of the College of Arts and Sciences at Cornell University, has accepted the presidency to succeed R. H. Jesse, who is to retire under the Carnegie retirement fund.

Nebraska University and Station.—Press reports state that Chancellor Andrews has resigned from the university. C. B. Anderson and George Coupland have been elected to the board of regents, and E. M. Little has been appointed assistant in dairying. A heating plant costing $30,000 has been added to the equipment, and a home economics building, costing $70,000, and a judging laboratory for the school of agriculture, costing $30,000, are approaching completion. The judging laboratory contains two class rooms for stock judging on the first floor, a class room and laboratory for agronomy on the second floor, and a seed room on the third floor. The attendance in the regular course of the school of agriculture for the current year is approximately 300. A course in home economics is now being offered with 25 students in attendance.

North Carolina College and Station.—According to *Breeders' Gazette*, C. M. Conner, agronomist, has accepted a position as assistant commissioner of agriculture for the Philippine Islands.

Ohio University.—V. M. Shoesmith, agronomist of the Maryland Station, has been appointed assistant professor of agronomy.

Oklahoma College and Station.—Under the new State constitution the State Board of Agriculture is made the board of regents of the college and station. The personnel of the board, as recently appointed, is as follows: J. P. Conners (president), Canadian; J. P. Roetzel (vice-president), Watonga; R. F.

Wilson, Valliant; D. M. Robb, Atoka; G. F. Bryan, Perry; Ewers White (treasurer), McLoud; Dan Diehl, Hobart; R. S. Burns, Fountain; R. P. Lindsey, Choteau; J. C. Elloott, Pauls Valley; and S. D. Dennis, Wellston.

Oregon College and Station.—A. L. Knisely, chemist, has resigned to enter the service of the Bureau of Chemistry of this Department. He will be connected with the food inspection work of the Bureau, and ultimately will be located at the branch laboratory soon to be opened at Portland, Oreg.

Porto Rico Station.—One of the largest sugar companies in the Island is actively cooperating with the station in cane breeding, furnishing two men for this work. Canes of promise will be distributed among the planters for trial.

Rhode Island College and Station.—In the college Warren B. Madison has been appointed professor of animal husbandry, and Daniel J. Lambert instructor in poultry husbandry. Wilhelm B. Quantz, Ph. D., has been appointed assistant chemist in the station in succession to H. S. Hammond, whose resignation was recently noted.

South Carolina College and Station.—A substation has been established in Summerville, where 300 acres of land has been donated for the purpose by the Southern Railway Co., adjoining its lines. The expense of equipment and maintenance is to be defrayed chiefly from college funds derived from State sources. About $5,000 is now being expended in installing a drainage system. Special attention will be given to problems involved in the reclamation of swamp areas and their adaptation to farm homes.

The enrollment of the college is rapidly increasing, especially in agricultural courses, where 248 students are now pursuing the four-year course. A new dormitory has been recently completed at a cost of $50,000, to accommodate 100 additional students.

Vermont University and Station.—The dedication of Morrill Hall, the new agricultural building, took place December 11. The State Grange actively cooperated in the exercises, and N. J. Bachelder, master of the National Grange, made the dedicatory address. In this he recounted the varied interests making for rural progress, and emphasized the necessity of individual initiative on the part of the farmers for the fullest realization of their purpose. Governor F. D. Proctor made the presentation address, and President Buckham the speech of acceptance. Director Hills, Mayor Bigelow of Burlington, Dean Bailey of Cornell University, and State Superintendent of Education Mason S. Stone were also among the speakers.

Morrill Hall is a substantial two-story and basement structure erected at a cost of about $60,000. The basement is to be fitted up for the dairy school, a farm creamery, a milk testing laboratory, and a market milk room. The main floor will contain the offices of the dean and director, and of the animal husbandman, a library and horticultural laboratories, offices, and class rooms, and the second floor the chemical laboratories of the station, a number of class and lecture rooms, and a soil physics laboratory.

In connection with the dedicatory exercises a federation of New England agricultural college clubs was organized on lines similar to the American Federation of Agricultural Students, by delegates from Maine, Vermont, New Hampshire, Massachusetts, and Rhode Island. Among other activities it is planned to issue a monthly circular letter on the work done at each institution, and an effort will be made to develop this into a quarterly publication. The next meeting is to be held in the fall of 1908 at the dedication of the agricultural building of the University of Maine.

Virginia College and Station.—S. W. Fletcher, Ph. D., of the Michigan College and Station, has been elected director of the station and professor of experimental agriculture, and entered upon his duties early in January.

Washington Station.—W. H. Lawrence, assistant botanist, has been appointed superintendent of the Puyallup Substation, and J. S. Friedley assistant superintendent.

West Virginia University.—C. P. Hartley, assistant bacteriologist, has resigned to accept a position with the department of botany of the University of Minnesota.

Wyoming Station.—In cooperation with the Bureau of Animal Industry of this Department, a somewhat extensive experiment in sheep breeding is in progress with a flock of 247 high grade and pure bred Rambouillet breeding ewes, and 6 pure bred Rambouillet rams. The experiment is to be conducted so far as possible under actual range conditions, the sheep being kept on the range during the entire year.

Office of Experiment Stations.—R. D. Milner, previously connected with the nutrition investigations of the Office, has been assigned to the departments of agricultural chemistry, dairying, dairy farming, and agrotechny in *Experiment Station Record* formerly covered by Dr. H. W. Lawson.

Poultry Investigations of the Bureau of Animal Industry.—The Bureau has completed the equipment of the poultry plant at its experimental station at Bethesda, Md., and the investigations are under way. The plant has a capacity of 325 laying hens, with sufficient range for the rearing of young stock. Records are being kept of the egg production by means of trap nests. The work also includes a comparison of dry and moist mash and the hopper methods of feeding, a comparison of the growth of capons and cockerels, and as to the possibility of replacing linseed meal in the ration by a small amount of cotton-seed meal.

M. M. Hastings, a graduate of the Kansas College, has been appointed an assistant in the poultry investigations and will make a study of problems relating to methods of production, transportation, and marketing of eggs and poultry.

Graduate School of Agriculture.—A preliminary announcement has been issued for the Graduate School of Agriculture to be held July 6–31, at Cornell University and the New York State Station. Courses will be offered in biochemistry, agronomy, horticulture, dairy husbandry and dairying, poultry farming, veterinary medicine, and entomology, with numerous conferences on various phases of agricultural work, and excursions to typical horticultural and dairy farms.

Agriculture and the National Education Association.—It is announced that at the meeting of the department of superintendence of the National Education Association in Washington, D. C., February 25–27, considerable attention is to be given to agricultural education. A round-table conference will be held at which the topics will include cooperation between the State agricultural college and the State normal school in training teachers for elementary agriculture, and cooperation by the United States Department of Agriculture and State school authorities in promoting agriculture in the public schools.

It is also planned to organize at this meeting a department of rural and agricultural education in the association coordinate with the existing departments. This action was authorized by the board of directors of the association at the July meeting in Los Angeles.

International Live Stock Exposition.—The eighth exposition of the International Live Stock Association, held in Chicago November 30 to December 7, continued the successes of previous years. In spite of the financial stringency and extremely disagreeable weather during the opening days the attendance was remarkably good, especially from the city and near-by points. This may be attributed in part to the attitude of the daily press of Chicago, which accorded the exposition much more adequate recognition than formerly. One prominent journal issued a special eight-page edition devoted to the exposition and its objects, magnitude, and special interest to city people.

The number of exhibits exceeded by 28 per cent the record of the year before, including 1,263 cattle, 665 horses, 375 hogs, and 1,146 sheep, or a total of 3,499 animals, and in most of the classes there was continued improvement in the quality of the entries as well. Seventeen States were represented, and the international scope of the exposition was once more demonstrated by entries from Canada, England, Scotland, and Germany, and the presence of visitors from these and many other foreign countries.

The influence of the agricultural colleges and experiment stations was again strongly in evidence. The list of judges included 13 members of their staffs, the students were, as in former years, a prominent and distinctive feature, and the exhibits of 11 institutions were distributed through nearly every class of entry.

In the fat stock division their predominance was especially marked. In the award of prizes in the open competitions, Ohio University again furnished both the champion Berkshire barrow and the grade champion pen of 3 of all breeds, besides many class prizes. The Iowa College had the champion pen of Poland Chinas, and won several prizes with other breeds, as did also Wisconsin, which received second on dressed carcasses from 100 to 200 lbs. in weight. A new feature was the exhibition by Cornell of a pen of Cheshires.

The exhibit of sheep from the Wisconsin University attracted much attention, especially several pens of lambs entered by the station in a comparison of different breeds and rations. At the close of the test the lambs were slaughtered and the carcasses graded. First place in the breed test was awarded to the Southdowns, closely followed by the grade Shropshires. In the feeding test, cracked peas, cracked barley, and cracked corn were compared as supplements to whole oats and bran, and with a ration of whole oats and cracked barley 1:1, the highest rating being given to the pen receiving cracked peas. Wisconsin was awarded first in a special competition for American bred Shropshires, with South Dakota second, and several other prizes went to these institutions and to the Missouri University. In the slaughter tests Wisconsin won first and second for one to two-year-old wethers with Iowa third, and was first for lambs with Iowa third.

For cattle, Ohio University won first for calves and the breed championship on Shorthorns, and other prizes went to Kansas, Nebraska, and Iowa. Minnesota won first for two-year-olds with the Aberdeen-Angus, third for yearlings, second and fourth for calves, and the breed championships both for single steers and herds. The Kansas College won a first for calves, a fourth for two-year-olds, and seconds for yearlings and herds; Nebraska a first for yearlings and thirds for two-year-olds and herds; Missouri a third, and Purdue a fifth for calves, and Iowa a fifth for herd.

For Herefords, the Minnesota, Nebraska, Purdue, and Missouri universities were among the prize winners. Iowa won third on yearlings with Peerless Wilton 39th's Defender, last year awarded as a calf the grand championship of the show. The Galloway winners were exclusively from the colleges and stations, Missouri receiving first on two-year-olds and calves, and the championships on single steers and herds, and Ohio first on yearlings, the remaining prizes going to these institutions, Iowa and Nebraska. Ohio also won first in the two-year-old class and the championship for single steers with the Red Polls.

In the grades and crossbreds the first place for two-year-olds went to the Colorado College, and Purdue received first for junior yearlings. Purdue, Nebraska, Missouri, and Iowa also received other prizes in this class. The champion herd of the show from all breeds was, as last year, from the Minnesota Station. The grand championship of the show again went to a calf, this time a grade Shorthorn, Roan King, exhibited by James Leask of Ontario. The second choice was the Angus two-year-old Andy of the Minnesota Station, which received the same position last year.

In the slaughter tests of fat cattle the Iowa College won a first for two-year-olds and a second for yearlings. In the former class Ohio University was third and Kansas fourth, and in the latter Nebraska won a third and a fifth.

Two of the stations, Purdue and Missouri, participated in the exhibits of carload lots of cattle. Missouri sent a drove of grade Herefords typical of the stock procurable in that section, and Purdue a load of "short fed" Herefords fed by a Purdue senior, which received the first premium in its class. Complete data as to kind and cost of feeding and actual profits were available, and the demonstration was regarded as of great value.

With horses the Iowa College was particularly successful, receiving first for light draft horses in harness, third for aged stallions, first and fourth for aged mares, and fifth for two-year-olds in Clydesdales, and first and third for aged mares, second for three-year-olds, and fifth for two-year-olds in Shires. Ohio won fourth place in Clydesdale yearlings.

In the special classes for college and station stock the competition was keener than ever before. In the cattle classes Minnesota won first on two-year-olds, cattle one to two years old, and the championships for a single steer and a pen of 5. Colorado was second for two-year-olds, Kansas third, and Iowa fourth. For calves Ohio was first, followed by Missouri, Iowa, and Kansas, and for cattle one to two years old Kansas was second, Nebraska third, and Purdue fourth. Wisconsin won all the prizes for sheep except first on wether lambs and third on wethers one to two years old, which went to Iowa. Ohio won third for barrows, the remaining prizes for hogs going to Iowa. For the best general exhibit of 5 each of cattle, sheep, and hogs Iowa was first and Ohio second.

The large attendance of students elicited the remark from *Breeders' Gazette* that "the agricultural college has made the International one of its elective courses." Delegations were on hand from Illinois, Missouri, North Dakota, Cornell, Texas, Ohio, Iowa, Kansas, Wisconsin, South Dakota, Washington, and Ontario, and teams from 10 of these colleges were entered in the various judging contests. The corn-judging trophy, valued at $1,500, was permanently awarded to Iowa, it having won the trophy for 3 successive years. Iowa also secured permanent possession of the valuable horse-judging trophy, while that for work in judging cattle, sheep, and swine was awarded to Ontario. It is expected that new trophies will be offered for future competitions.

The Armour scholarships contingent upon these contests and the prize winnings of the colleges and stations have been awarded as follows: To Iowa 7, to Missouri 3, to Ohio, Minnesota, Nebraska, and Wisconsin 2 each, and to Purdue and Kansas 1 each. Of the Rosenbaum prizes for the greatest aggregate prize winnings of exhibitors from the respective States, the first prize of $500 was awarded to the Illinois University, the second of $300 to the Iowa College, and the third of $100 to Wisconsin.

Southern Commissioners of Agriculture.—The Southern States Association of Commissioners of Agriculture and Other Agricultural Workers held its annual meeting at Columbia, South Carolina, November 19–21. During the sessions Assistant Secretary of Agriculture W. M. Hays discussed agricultural education, reviewing the rise of the agricultural colleges and advocating the centralization of the rural schools, the establishment of agricultural high schools, and the closer organization of farmers for mutual benefits.

Other addresses were delivered by B. H. Rawl, of the Dairy Division of this Department, on Cooperative Demonstration Work in Dairying in the Southern States; by Dr. C. A. Cary, of the Alabama Station, on The Relation of Farmers' Institutes to Demonstration Work; by T. B. Parker, of the North Carolina State Station, on Field Demonstration Work by State Departmens of Agriculture; by W. R. Dodson, of the Louisiana Station, on the Cooperation and Coordination of the Work of State Departments of Agriculture and State Experiment Stations; by C. L. Willoughby, of the Georgia Station, on Cooperation Between the Experiment Stations in the Cotton Producing States, and by A. M. Soule, of the Georgia College, on Cooperative Demonstration and Institute Work.

Considerable discussion followed these papers as to the respective functions of the State departments of agriculture and the colleges and stations in extension work, and a standing committee was appointed to report on the subject at a subsequent meeting. Commissioner J. A. Wilkinson of Alabama discussed new work for departments of agriculture, advocating official soil surveys, work in seed selection, and forest preservation, some of these phases being presented in further detail by J. L. Bryan and C. L. Hill. The Relation of the Manufacturer to the User of Fertilizers was discussed by F. B. Dancy. New Nitrogenous Fertilizers by F. B. Carpenter, and the Phosphates of Florida by E. H. Sellards, formerly of the Florida Station.

At the election of officers, Commissioner Thomas G. Hudson, of Atlanta, Ga., was chosen president, and Director B. W. Kilgore of the North Carolina State Station, secretary. The convention of 1908 will be held at Nashville, Tenn.

National Drainage Association.—The first annual congress of this association was held in Baltimore, Md., November 25–27. The programme included an illustrated lecture on Salt Marsh Drainage in New Jersey, Direct and Indirect, by J. B. Smith, of the New Jersey Station; papers on The Status and Present Need of Agricultural Drainage, by C. G. Elliott, chief of the drainage investigations of this Office; The Control of Floods by Farm Management, by W. J. McGee, of the Bureau of Soils; and Forests in Their Relation to Drainage, by Gifford Pinchot, of the Forest Service. There were also papers and addresses on various aspects of drainage problems, especially as to the needs of a national drainage law, by Secretary of the Interior Garfield, Attorney-General Bonaparte, United States Senators Flint of California and Newlands of Nevada, Governor Broward of Florida, and others. Governor Broward was elected president of the association, and the next meeting will be held in Washington in May, at the time of the inland waterways convention.

Measures before Congress.—Among the bills recently introduced into Congress are the following: To provide from the receipts from forest reserves an annual appropriation of $2,500 to each college of agriculture and mechanic arts for instruction in forestry, and $2,500 to each experiment station for experiments in forestry; to provide an appropriation to each agricultural college for instruction in mining; to establish mining experiment stations; to establish engineering experiment stations at agricultural colleges with an annual appropriation of $30,000; providing an appropriation to the State normal schools for instruction in agriculture and manual training; to establish the University of the United States; to establish additional experiment stations in South Carolina and Mississippi; to establish an experimental wood distillation laboratory; to provide for a soil survey in Hawaii; to provide for grain inspection and standardization; directing the fixing of a standard of cotton classification; to provide for taking a census of agriculture; to grant the franking privilege to State and Territorial departments of agriculture; to amend the patent laws in the interest of originators of horticultural products; appropriaing $250,000 for the gipsy moth work,

$100,000 for the extermination of the green bug and other grain pests, and $100,000 for experiments in dry farming; and to provide for the printing of 100,000 copies of the special report on the diseases of cattle.

Miscellaneous.—An American Society of Agronomy was formed on the occasion of the meeting of the American Association for the Advancement of Science at Chicago during the holidays. The officers of the society are M. A. Carlton, president; C. P. Bull and B. M. Duggar, vice-presidents; T. L. Lyon, secretary, and E. G. Montgomery, treasurer. The object of the society is to encourage investigation in the field of agronomy, and to afford an opportunity for the discussion of methods and results.

The Association of Economic Entomologists at its meeting in Chicago decided to establish a Journal of Economic Entomology to be issued bimonthly, and to include the proceedings of its meetings, original papers, reviews, and notes. E. P. Felt, of New York, was elected editor, and E. D. Sanderson, of New Hampshire, business manager.

The Entomological Society of America has also decided to begin the issue of a series of memoirs.

A series of practical garden talks is announced by Secretary H. D. Hemenway of the Home Culture Clubs of Northampton, Mass., to be given at various times during the winter.

J. B. Farmer, professor of botany in the Royal College of Science in London, has accepted the editorship of *The Gardener's Chronicle* in succession to the late Dr. Maxwell T. Masters.

A further grant of about $1,000 a year has been made by the Drapers' Company to Cambridge University to be applied toward the salary of a professor of agricultural botany, and it is hoped to establish such a chair in the near future.

J. R. Sage has resigned the office of director of the Iowa Weather and Crop Service after nearly 18 years' service.

W. E. Collinge has resigned the professorship of economic zoology in Birmingham University to accept the directorship of the Cooper Research Laboratory at Berhamsted.

Dr. G. Delacroix, director of the station for plant pathology connected with the National Institute Agronomique, died in Paris on November 2, 1907.

O

EXPERIMENT STATION RECORD.

VOL. XIX. FEBRUARY, 1908. No. 6.

The International Institute of Agriculture, at Rome, is a unique institution. It is in a class by itself. It is not for instruction, as some inquiries would imply, but strictly for investigation, the collection of data, and the prompt dissemination of information of interest to the nations of the earth. It is to deal especially with the economics of agricultural production and distribution, and with the sociological problems of agriculture. Its novel character makes the plans for its development a matter of no small interest.

Credit for the conception of an international institute of agriculture belongs to an American, Mr. David Lubin, of California, who sought the assistance of the King of Italy in carrying the idea into effect. The plan appealed to the King, who issued a call, through the Italian ambassadors, to the different nations of the world for a conference at Rome to consider the advisability of establishing such an international institute. The conference took place in May, 1905, one hundred and fourteen delegates representing forty countries being present. After deliberating something over a week on the matter, the "acte final" was adopted and signed by the delegates present, providing for the establishment of the institute and outlining its constitution and functions. The convention was afterwards ratified by plenipotentiaries of the respective countries. Twenty-five nations, including nearly all of agricultural importance, have joined in the undertaking and pledged their support.

This country has made an appropriation of $4,800 for the payment of its quota toward the support of the institute for the fiscal year 1907, and $8,600 for the salary of a member of the permanent committee and for the expenses of delegates to the general assembly of the institute. The Italian Government is erecting a palace in the gardens of the Villa Borghese in Rome, to serve as headquarters of the institute. This is a handsome two-story building, containing an assembly hall, and executive and clerical offices. Announcement has been made that the first meeting of the permanent committee in charge of the institute will be held this spring, and the institute will be inaugurated and enter upon active work as soon thereafter as possible.

In the meantime the Italian Royal Commission has instigated an inquiry into the exact character and extent of the information which the different countries are in position to supply with regard to their agricultural production. This information will be catalogued and classified, and a report upon it will be ready for the use of the permanent committee when it meets. The systems in operation in various countries for the collection of agricultural statistics are also being studied, in order that the value of these statistics may be judged of and means of improvement suggested where desirable.

The functions of the institute are strictly economic and sociological. While its duties have not been worked out in detail, the "acte final" prescribes as among the principal duties that the institute shall collect, study, and publish as promptly as possible statistical, technical, and economic information of interest to agriculturists, excluding "all questions relating to the economic interests, the legislation, and administration of any particular nation." More specifically the data sought for publication relate to the cultivation of the soil, crop production, trade in and prices of agricultural products on the various markets, wages of rural labor, the appearance, spread and means of control of new diseases of plants. It will also give special attention to the subjects of agricultural cooperation, insurance, and credit. It is designed, therefore, to serve as a great intelligence bureau of the countries interested, for the dissemination of information relating to agricultural production throughout the world, and many economic and social phases of agriculture.

The finances of the institute are cooperatively provided. The calculated annual expense of the institute is about $175,000. Toward this sum the King of Italy has given the revenues of two domains near Pisa, which amount annually to $60,000. The balance of $115,000 is to be raised among the nations on the basis of units of subscription, which also determine the national representation and voice in the management of the institute. Five groups are recognized. Group 1 carries five votes and sixteen units of subscription, group 2 four votes and eight units, group 3 three votes and four units, group 4 two votes and two units, and group 5 one vote and one unit of subscription. For the first two years a unit of subscription is placed at $300 per annum, and the constitution provides that it can never be more than $500. The subscriptions therefore range from $300 to $4,800 per annum. Each nation elects the group it will join in the management and support of the enterprise. The United States has come in on the basis of group 1.

The control of the organization is placed in the hands of a general assembly of delegates, sent by the adhering nations and presided over by an elected president and two vice-presidents. The permanent committee, composed of members designated by the respective governments, is intrusted with the executive management of the institute, under the direction and control of the general assembly. Members of the committee may serve as the representative of one or more nations, but the actual number of members is to be not less than fifteen. The general secretary will act both for the committee and the assembly.

Thus there is brought into existence a real parliament of the nations, with a permanent cabinet and ministry devoted solely to a consideration of agricultural interests. It is a significant step in international cooperation, and the more so because it is directed toward the greatest of international industries and the one most far-reaching in its sociological influences. It signifies a uniting of forces in peaceful and productive occupations in mutual aid for mutual benefit. As such it is noteworthy as marking another step in the progress of civilization.

The question of suitable provision for publishing reports of the more scientific investigations carried on at the experiment stations, especially those under the Adams fund, is already attracting attention and will soon become an important one. It is generally recognized that these will not in their entirety or original form be suited to the regular series of bulletins. While the results of work of this character will ultimately prove of very great benefit to agriculture, its details will ordinarily have little interest for farmers or the general public. At the same time, in order to satisfy the proper demands of the scientific world and to give our agricultural investigators and students the information they should have regarding these researches, it will be highly desirable to have them published in as much detail and with as complete illustration as is usually done in the case of work of the same order in other branches of science.

Referring to this matter, the report of the Director of this Office, just issued, points out that this will mean the providing of a different class of publications from the ordinary station bulletins and reports. Either the individual stations must establish with the aid of State funds a technical series of publications, which, though limited in editions, will be relatively elaborate and expensive, or Congress must make provision for the grouping together of the scientific work of the stations in a general series of special publications to be issued under the authority of the National Government.

To the world at large the latter course would undoubtedly be the most satisfactory, since this would bring the research work of the stations together and establish a regular and permanent medium for its publication, thus making it readily accessible to scientists and students the world over. Foreign critics of our experiment station system have often expressed the view that under present conditions the national character of our system of agricultural research was obscured and the scientific value of much of the work of our stations was lost sight of because of the miscellaneous character of the station publications, and the multiplicity of the sources from which they emanated. There is little doubt that our stations would have a much better standing in the scientific world if their more scientific publications were differentiated from their popular ones and issued through a single regular channel.

The report suggests the possibility of establishing an editorial board through the Association of American Agricultural Colleges and Experiment Stations to represent the interests of the stations in this matter, and that this board might act in cooperation with this Office in the preparation for the press of reports submitted by the individual stations. There is ample time for the elaboration of this or some other satisfactory plan for securing the suitable publication of the scientific work of the stations, but it is felt that this problem should be carefully considered with a view to reaching a satisfactory solution in the near future.

The necessity for the exercise of patience in research, both by those who are prosecuting it and especially by the prospective beneficiaries, is emphasized in an address by Dr. D. P. Penhallow, published in a recent issue of *Science*. The address was delivered on the occasion of the opening of Clark Hall, the new botanical building at the Massachusetts Agricultural College.

Doctor Penhallow, for many years professor of botany in McGill University, is not actively engaged in agricultural research but he is quite familiar with the history of its development, and he makes an appeal which is especially opportune at this time. He points out that "nature's processes, although exceedingly certain of fulfillment, are nevertheless exceedingly slow. If it has taken five hundred million years to shape this earth and render it a fit habitation for man, man himself must not be impatient if he is required to spend a few years of arduous toil that he may unlock some of the doors which so carefully guard nature's secrets. Sixty-three years sped on their way from the time when Boussingault first endeavored to ascertain the source of nitrogen in plants, until a satisfactory explanation was reached through our knowledge of the action of root tubercles; and for more than sixty years Lawes and Gilbert sought the solution of plant nutrition without gaining the end in view.

"The laws of nature are not kept on draught, as it were, to be drawn in large or small quantity, according to the demand. To present a problem to an investigator and expect an immediate solution, or an immediate practical application, is to be prodigal of a costly equipment, to sacrifice unnecessarily the best and most carefully trained intellectual strength, and to bring discouragement and invite failure.

"It is no doubt true that when a commonwealth has invested a large amount of capital in specially trained men and expensive apparatus, it is reasonable to ask for results, and with this no fault can be found. The danger lies in the fact that sufficient opportunity is not allowed for the careful working out of a problem in all its scientific aspects. Under conditions of haste and undue pressure, the results, if worth anything, are very likely to be incomplete and unsatisfactory, and in too many cases they must be subject to costly revision.

"I feel disposed at this time to make an appeal to the citizens of this commonwealth to secure to the investigators who will occupy this building, as well as to all others in this college, freedom for the future from an incubus which, in the history of our experiment stations of the past, has for many years been prolific of disastrous results. I do this because this building should stand as an exponent of the best scientific work and thought, and because I know of no body of men, other than the citizens of Massachusetts, to whom such an appeal may be made with greater assurance of an intelligent hearing, and a fairer prospect that they will apply the remedy, *patience*."

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Practical agricultural chemistry, F. D. S. ROBERTSON (*London, 1907, pp. X+210; rev. in Chem. News, 95 (1907), No. 2477, p. 237; Nature [London], 76 (1907), No. 1967, p. 246*).—This book attempts to give a complete laboratory course of practical chemistry for agricultural students, including quantitative analysis of solutions containing the commoner metals and acid radicals. Gravimetric analysis and simple volumetric determinations are treated, the more technical part of the book dealing with analyses of soils and phosphatic fertilizers, feeding stuffs, dairy products, oils and fats, sugars, tea, coffee, cocoa, alcoholic beverages, and water.

Agricultural chemistry. I, Nutrition of plants, K. GRAUER (*Agrikulturchemie I. Pflanzenernahrung. Leipsic, 1907, pp. 106; rev. in Österr. Chem. Ztg., 10 (1907), No. 18, p. 258*).—This little book gives in small compass a simple but quite complete review of the present status of knowledge relating to the chemical composition of plant substances, plant nutrition, chemical and physical properties of soils, and fertilizers.

Official and provisional methods of analysis, H. W. WILEY ET AL. (*U. S. Dept. Agr., Bur. Chem. Bul. 107, pp. XXIII+230, figs. 11*).—This bulletin is a revision of Bulletins Nos. 46 and 65 of the same Bureau, and includes all authorized changes and additions made prior to its publication. General and special methods have been rearranged and consolidated, and repetitions or contradictory material have been eliminated.

Volumetric determination of nitrogen in nitrates, J. G. C. VRIENS (*Ztschr. Analyt. Chem., 46 (1907), No. 6–7, pp. 414–420; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 538, II, p. 651*).—The method described is based upon the oxidation of ferrous ammonium sulphate when boiled with sulphuric acid and nitrates. The extent of oxidation is measured by means of a 0.1 per cent solution of potassium ferricyanid, a blue coloration indicating excess of iron salt, a brown color too little. "Separate portions of the nitrate solution are treated . . . with increasing (or decreasing) quantities of the iron solution until with one test a blue coloration is obtained on adding the indicator, whilst the next successive test, containing 0.1 cc. more of the iron solution, gives a brown coloration" when observed within 30 seconds after adding the indicator.

"The presence of considerable quantities of potassium sulphate, ammonium sulphate, and sodium oxalate has no influence on the results obtained by the method."

The coloring of nitrifying organisms, W. OMELIANSKI (*Centbl. Bakt. [etc.], 2. Abt., 19 (1907), No. 7–9, pp. 263, 264*).—A modification of Thesing's method is described.

Determination of phosphoric acid as phosphomolybdic acid, G. JÖRGENSEN (*Ztschr. Analyt. Chem., 46 (1907), No. 6–7, pp. 370–392, pl. 1; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 538, II, p. 652*).—The author concludes from extended studies of this method that to obtain accurate results by its use the excess of molybdic acid solution should not be large, the precipitate should be allowed to settle for 24 hours at ordinary temperature before being collected on a filter, and the precipitate and filter should be ignited at a moderate heat over an Argand burner with constant stirring until the filter paper is completely burned. The compound thus obtained has the formula $P_2O_5.24MoO_3$.

An important question in the fertilizer industry, E. H. Schultze (*Chem. Ztg., 31 (1907), No. 65, p. 801*).—Attention is called to the importance of accurate determination of the water-soluble phosphoric acid in superphosphates, and it is asserted that no method for the determination of free phosphoric acid has yet been proposed which gives reliable results.

Determination of calcium oxid, magnesium oxid, and phosphoric acid by means of the Zeiss refractometer, B. Wagner and F. Schultze (*Ztschr. Analyt. Chem., 46 (1907), No. 8, pp. 501–508, figs. 3; abs. in Chem. Zentbl., 1907, II, No. 10, pp. 844, 845*).—The calcium is precipitated as oxalate, converted first to oxid and then to acetate, and in this form examined in the refractometer. The magnesium and phosphoric acid are precipitated as ammonium-magnesium phosphate and a sulphuric acid solution of the precipitate examined in the refractometer.

Dolomite and magnesite with reference to the separation of calcium and magnesium, N. Knight and W. H. Wheeler (*Proc. Iowa Acad. Sci., 13 (1906), pp. 167–171*).—Further experience with a method of precipitation of lime with ammonium oxalate in solutions of calcium and magnesium chlorid as described in Proceedings of the Iowa Academy of Science for 1903, p. 127, are reported, with critical comments on other proposed methods and studies of conditions affecting accuracy of the separation of calcium and magnesium.

The estimation of lime and magnesia in water by volumetric methods, W. T. Burgess (*Analyst, 32 (1907), No. 375, pp. 208–214, fig. 1; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 537, II, pp. 578, 579*).—The method for lime is based upon precipitation with ammonium oxalate and titration of the excess of oxalate with potassium permanganate. The magnesia is determined by precipitation with sodium hydroxid and determination of the alkalinity of the supernatant solution.

Chemical and bacteriological standards now in use in water analysis, J. H. Kastle (*Jour. Biol. Chem., 3 (1907), No. 3, pp. XXXV, XXXVI*).—The various chemical and bacteriological standards now in use in water analysis are reviewed and discussed.

Logarithmic factors for use in water analysis, W. S. Hendrixson (*Proc. Iowa Acad. Sci., 13 (1906), pp. 173, 174*).—A series of logarithmic factors for recalculating results of water analysis is given.

Investigations on the solubility of phosphoric acid and on the hygroscopicity of certain typical soils of Skaraborg County, G. Nannes (*Inaug. Diss., Univ. Königsberg, 1906, pp. 98*).—The investigations reported in full in this paper have already been more briefly reported in separate articles (E. S. R., 18, pp. 208, 318).

Available plant food in soil, W. A. Hargreaves (*Jour. Dept. Agr. So. Aust., 10 (1907), No. 7, pp. 420–425; Dept. Agr. and Intel. So. Aust. Bul. 20, pp. 7*).—This article reviews investigations relating to chemical methods of determining available plant food in soils and states the history of such work to be a "record of comparative failure."

Analysis of egg yolk, N. A. Barbieri (*Compt. Rend. Acad. Sci. [Paris], 145 (1907), No. 2, pp. 133–135*).—The author identified in egg yolk tristearin, triolein, cholesterin, crystallized sulphur, and a substance rich in phosphorus and similar to the body which has been called cerebrin for which the name "ovin" is proposed.

Milk coagulating agents in the juice of the Chinese mulberry, C. Gerber (*Compt. Rend. Acad. Sci.* [*Paris*], *145* (*1907*), *No. 12, pp. 530–532*).—The author found from experiments that there exists in the juice of the Chinese mulberry (*Broussonetia papyrifera*) an activating substance without which the coagulating diastase is incapable of causing curdling of milk. The action of these two substances resembles that of alexin and its sensitizing agent in hemolytic serums and bactericides, or that of trypsin and kinase in the intestinal juice.

The structure of the starch grain, II, H. Kraemer (*Amer. Jour. Pharm., 79* (*1907*), *No. 9, pp. 412–418*).—By the treatment of definite amounts of starch with definite quantities of iodin solution it may be shown that the amount of soluble starch varies in starch grains of different origin.

In summing up the observations on the behavior of iodin and starch, the author states: "That we are dealing with a chemical compound of iodin and soluble starch; but that the combination is a feeble one, being easily dissociated upon the application of heat, and the iodin being more or less volatilized. Also the facility with which soluble starch takes up the iodin in a chloroformic solution indicates that the affinity of starch for iodin is considerably greater than heretofore supposed."

A method of staining starch is described in which an aqueous solution of iodin and gentian violet is used. The method is especially adapted to wheat starch and corn starch, but in the case of potato and maranta starches weaker iodin solutions are necessary and for these two starches the method is not entirely satisfactory. Earlier work has been noted (E. S. R., 19, p. 259).

On some applications of safranin as a test for carbohydrates, H. MacLean (*Bio-Chem. Jour., 2* (*1907*), *No. 9, pp. 431–442*).—The experimental data reported are favorable to the use of safranin.

"Safranin is a general test for carbohydrate bodies of a certain type, and is one of the most suitable reagents for determining the presence of traces of carbohydrates in liquids; it is unaffected by all the ordinary 'interfering' substances of urine except those of a carbohydrate nature.

"Safranin is not decolorized by albumin after long boiling, but the presence of albumin in the liquid to be tested interferes with the delicacy of the reaction; ammonia in excess acts in a somewhat similar manner.

"In digestion experiments the amount of starch changed can be comparatively easily obtained, while the differences in the carbohydrate contents of urine or blood, after standing for some time, as the result of glycolytic action, can be easily and fairly accurately determined. . . .

"The [reported data] indicate the uses of safranin for solutions containing small amounts of carbohydrate, and while the reagent possesses certain disadvantages with regard to its use as a routine test for the examination of urine in unskilled hands, it often proves exceedingly useful for the detection of traces, especially when combined with yeast fermentation."

Colorimetric determination of the albumin contents of barley, with Millon's reagent, C. J. Lintner (*Brewers' Jour., 31* (*1907*), *No. 12, p. 553*).—A modification of Millon's reagent is described, which, according to the author, gives satisfactory results in determining the albumin content of barley.

Determination of the starch contents of barley by polarization, C. J. Lintner (*Brewers' Jour., 31* (*1907*), *No. 12, pp. 555, 556*).—The report of data show that the starch content decreases as the protein content increases and this relation, according to the author, seems to be more clearly expressed "by the figures obtained with the polarization method than by those obtained from the methods of steaming."

Saccharid and nonsaccharid constituents of sugar beets, their properties, chief compounds, and the most important products of transformation and decomposition, G. S. Likhovitzer (*Separate from Vyestnik Sakh. Promuish., 1904–5, pp. 246; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.] 8 (1907), No. 1, pp. 88, 89*).

Analyses of cane and beet sugar in sugarhouses and refineries, C. Fribourg (*L'Analyse Chimique en Sucreries et Raffineries de Cannes et Betteraves. Paris, 1907, pp. XII+390, figs. 51*).—A handbook of sugar chemistry and laboratory methods designed especially for the use of sugarhouse chemists.

Polarimetric estimation of sugars in honey, J. Fiehe (*Ztschr. Untersuch. Nahr. u Genussmtl., 14 (1907), No. 4, pp. 299–304*).—A polemical discussion of methods with special reference to pure and adulterated honey.

The detection of bleached flours, F. J. Alway and R. A. Gortner (*Jour. Amer. Chem. Soc., 29 (1907), No. 10, pp. 1503–1513*).—According to the authors' investigations, "a bleached flour may with certainty be distinguished from an unbleached flour, and the kind of bleaching agent employed may be identified as nitrogen peroxid or halogen. The amount of bleaching agent that has been applied to a flour may be estimated from the amount of certain reaction products remaining in the flour.

"With the Griess-Ilosvay reagent all flours bleached by means of nitrogen peroxid give a pink coloration, while unbleached flours give no coloration. Only when extreme precautions are observed is the test reliable.

"Bleached flours lying alongside of unbleached flours do not give off any substance which will so affect the latter that they will give the test for bleached flours. Neither nitrogen peroxid nor nitrous acid is present in bleached flours, the characteristic reaction being produced by nitrites.

"The amount of nitrites in bleached flours is very small, the average being 6.3 parts per million for all the samples examined. There is little difference in the amount of nitrites produced by the two kinds of bleachers.

"The amount of nitrite in a bleached flour is approximately proportional to the amount of nitrogen peroxid that has been used. The average amount of the bleaching agent used by 25 Nebraska mills would accordingly be approximately 5 cc. per kilogram of flour."

The analysis of ice cream, C. D. Howard (*Jour. Amer. Chem. Soc., 29 (1907), No. 11, pp. 1622–1626*).—The author gives notes regarding the methods in use in the New Hampshire laboratory of hygiene in the determination of fat, character of the fatty matter, chemical preservatives, fillers, and "mechanical preservatives" in the analysis of ice cream.

The estimation of boric acid and borates in food stuffs and commercial products, R. J. Manning and W. R. Lang (*Jour. Soc. Chem. Indus., 26 (1907), No. 14, pp. 803, 804*).—The methods described for determining boric acid in milk and borates in methyl alcohol and salt depend upon distillation and precipitation as barium borate and upon distillation and titration. An additional titration method for the detection of boric acid in milk is given which has not yet been completely worked out.

Salting out cocoa fat soaps as a means of identifying cocoa fat, R. Cohn (*Chem. Ztg., 31 (1907), No. 70, pp. 855–857*).—The author's results were favorable to the use of this method for the detection of cocoa fat. In his opinion, the salting out method gives satisfactory results for detecting the presence of capronic, caprylic, and caprinic acid in other bodies than fats.

The influence of oxygen and of nitrogen, and sunlight and darkness on olive oil as affecting the iodin and saponification numbers and the production of rancidity, L. A. Ryan and J. Marshall (*Amer. Jour. Pharm., 79 (1907),* *No. 7, pp. 308–315*).—From the experiments reported the authors conclude that the effect of oxygen on olive oil is to decrease the iodin number and increase the saponification number. It also has a marked tendency to induce rancidity and diminishes the color originally possessed by the oil. Unsterilized oil exposed to diffused sunlight showed a higher iodin number and a lower saponification number than sterilized oil similarly treated. Sterilized oil kept in the dark had a slightly higher iodin number and a slightly lower saponification number than similar oil exposed to diffused sunlight.

Nitrogen, under the experimental conditions, did not affect the iodin number of sterilized or unsterilized oil, though it increased the saponification number of sterilized oil.

The determination of arsenic and other solid constituents of smelter smoke, with a study of the effects of high stacks and large condensing flues, W. D. HARKINS and R. E. SWAIN (*Jour. Amer. Chem. Soc., 29 (1907), No. 7, pp. 970–998, figs. 7; abs. in Chem. Zentbl., 1907, II, No. 11, pp. 936, 937*).

Chemical novelties for 1907, C. POULENC (*Les Nouveautés Chimiques pour 1907. Paris, 1907, pp. XI+347, pl. 1, figs. 196*).—This publication contains condensed accounts, with illustrations, of new laboratory apparatus and new methods of research applied to science and industry, among which are some of interest in agricultural investigations. For example, on pages 279–311 is given the description of apparatus employed by Bordas and Touplan in the application of their method for a rapid and complete analysis of milk.

METEOROLOGY—WATER.

Report of the meteorological committee, Great Britain (*Rpt. Met. Com. [Gt. Brit.], 1907, pp. 150, pls. 7, fig. 1*).—This consists as usual of administrative reports regarding organization and operations (during the year ended March 31, 1907) in marine meteorology, forecasts and storm warnings, climatology, publication, and miscellaneous subjects, with appendixes relating to telegraphic reports from Iceland, supply of information to the public, lists of captains who sent in "excellent" meteorological logs during the year and of logs and documents received from ships, distribution of instruments, report on inspection of meteorological stations, list of persons and institutions from whom publications and meteorological data have been received and to whom publications are sent, and financial statement.

Among the papers on special investigations reported as completed during the year are: Temperatures as Indicated by Spirit Minimum and Mercury Minimum Thermometers, by C. Chree; The Observations of Atmospheric Electricity, by C. T. R. Wilson; Temperatures in the Screen and in the Open Air, and Aspiration Psychrometer Readings, etc., by W. H. Dines; Wind Measurements, by R. H. Curtis; An Apparent Periodicity in the Yield of Wheat in Eastern England, 1885–1905, by W. N. Shaw (E. S. R., 18, p. 713); and The Line Squall of February 8, 1906, by R. G. K. Lempfert.

An important development in forecast methods during the year was "the introduction of the consideration of frequency of occurrence into the representation of the weekly results [as] necessitated by the decision to give in the Weekly Weather Report a brief verbal representation of the character of the weather in successive weeks that might be useful for agricultural purposes."

It was found that the simple average or arithmetic mean would not serve this purpose. The weekly reports for the years 1881 to 1905 were therefore examined with reference to frequency of occurrence of accumulated temperature above and below 42°, rainfall, and sunshine, grouping the data so that "of the total number of weekly values for each element included in the period mentioned above, one-third are characterized as moderate, one-third fall on the side of excess, and one-third on the side of defect. A further subdivision is effected by prefixing the adverb 'very' to the description in the case of one-twelfth of the values reckoned from either extreme. . . .

"The first step in the process of fixing the limits consisted in the determination of the average value for each week for each element and for each district. The average values, found by taking the mean in the usual manner, were then smoothed by Bloxam's formula $\frac{A+2B+C}{4}$, and the results adopted as averages 'for the time of the year.' Subsequently the frequency distributions of the divergencies from these smoothed averages were determined for each element. From these, working diagrams were prepared for each district. . . .

"The classification has been undertaken with the object of summarizing in a convenient form the meteorological characteristics of a long period, such as a season or a year, by enumerating the number of weeks of each kind experienced within it, and tables are given in each issue of the report summarizing the weather of the current season and of the past four seasons on these lines. By this means it is hoped that the comparison of meteorological results with other statistics will be facilitated."

The afternoon harvest forecasts were continued as in previous years, 87 per cent of them being completely or partially successful. Of the regular forecasts for the whole of the British Isles 85.5 per cent were successful.

Meteorological report, F. SMITH (*Wyoming Sta. Rpt. 1907, pp. 141–143*).—Summaries are given of observations at Laramie, Wyo., on pressure, temperature, precipitation, humidity, sunshine and cloudiness, and wind movement during 1906. The mean annual temperature was 44.6° F., and the total precipitation 12.57 in., which is about 2.5 in. larger than the average for the last 16 years.

Meteorology, J. H. HART (*Trinidad Bot. Dept., Bul. Misc. Inform., 1907, No. 56, pp. 318–320; Ann. Rpt. Supt. Roy. Bot. Gardens [Trinidad], 1906–7, pp. 19–25*).—Summaries are given of observations at St. Clair, Trinidad, of pressure, temperature, and rainfall from 1888 to 1906, inclusive, with somewhat more detailed data for each month of 1906. The mean annual temperature recorded for 19 years is 78.5° F., the annual rainfall 66.4 in., and the mean annual relative humidity 79. The conditions during 1906 agreed closely with these normals.

[**Meteorological records, Fiji Islands, 1875–1906**] (*Leg. Council Fiji Paper No. 13, pp. 13–16*).—Monthly and annual means of temperature, pressure, rainfall, and humidity are given for the period 1884 to 1906 at Suva, and for the period 1875 to 1885 at Levuka; also detailed observations for the year 1906 at Suva, and mean monthly rainfall for the same year at a number of different points in the islands.

On the meteorology of the Nile Valley, H. G. LYONS (*Met. Ztschr. [Brunswick] 24 (1907), No. 5, pp. 205–212*).—This article is based on a report by the author which has already been noted (E. S. R., 18, p. 424).

The cold spring of 1907, A. J. HENRY (*Mo. Weather Rev., 35 (1907), No. 5, pp. 223–225*).—The weather map features accompanying the cold spring of 1907 are reviewed and other cold seasons of previous years are described. The conclusion is reached that "the underlying causes of the recent cold weather are probably obscure and deep seated, [but] that the chance of injury to the staple crops of this country by reason of a backward spring is rather remote, provided, of course, a sufficient amount of heat is supplied in June. . . . Drought and heat are much more likely to make serious inroads on the crops than are the chilling blasts of April and May."

Cyclonic distribution of precipitation, J. A. UDDEN (*Proc. Iowa Acad. Sci., 13 (1906), pp. 223-225, pl. 1*).—From the results obtained by a method described in an earlier report (E. S. R., 17, p. 531) the following conclusions are drawn:

"(1) That the area of greatest precipitation is not the same for different stations. They suggest that the cyclonic distribution of precipitation bears a definite relation to climate, and varies with this.

"(2) That if the area of greatest precipitation is to the southeast of the center of cyclones in the Upper Mississippi Valley (as taken for granted hitherto in general works on American meteorology) there must be a very marked diurnal shifting of this area concerning which nothing is as yet known; for to make up for the deficiency of precipitation in this part of the composite cyclone of the morning hour there would have to be a corresponding excess during some other part of the day.

"(3) That in either case the variations in the location of this area of greatest precipitation, be they local or diurnal, are quite probably of sufficient magnitude to appreciably affect the accuracy of weather forecasts."

The influence of precipitation on the yield and quality of crops, W. SCHNEIDEWIND ET AL. (*Landw. Jahrb., 36 (1907), No. 4, pp. 574-581, pl. 1*).—Observations during the period 1896 to 1906 on the influence of precipitation on (1) the yield of crops in general, (2) the yield of individual crops, and (3) the quality of the crops, are summarized and discussed.

The observations show that in dry years with lower yields the seed crops were richer in protein and the root crops richer in carbohydrates and protein than in wet years and thus that the net outcome is not so small as the gross results would indicate. High-bred resistant sugar beets showed less variation in dry and wet years than common varieties. The high-protein barley grown in dry years is less valuable for brewing than lower protein barley.

Forests and rainfall in West Prussia and Posen and the influence of wind on rain and snow measurements, J. SCHUBERT (*Ztschr. Forst u. Jagdw., 38 (1906), No. 11, pp. 728-735, figs. 4; abs. in Science, n. ser., 26 (1907), No. 668, p. 518*).—A critical study.

Man's influence on climate, T. R. SIM (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 7, pp. 717-724*).—This article discusses local influence on climate due to building of structures of various kinds, drainage, and the smoke and fumes of manufacturing establishments, but more particularly the wider influence exerted by the maintenance or destruction of vegetation on the surface of the earth.

Protection of buildings from lightning, A. R. SAWYER and L. J. SMITH (*Michigan Sta. Bul. 249, pp. 17-35, figs. 5*).—This bulletin gives rules for the erection of lightning conductors, as issued by the Lightning Rod Conference in 1882, with observations thereon by the Lightning Research Committee, 1905, and describes the system of lightning protection used on the college barns, with details of its construction.

River discharge, J. C. HOYT and N. C. GROVER (*New York and London, 1907, pp. VIII+136, pls. 7, figs. 24*).—This book attempts to bring together from all available sources information in regard to the best practice, in suitable form for the use of students and engineers. "Much new matter is also presented, especially the descriptions of the conditions necessary for good gaging stations at which measurements of discharge may be made either by weir, current meters, floats, or slope; the routine of the selection, establishment, and maintenance of gaging stations; the details of the field work of discharge measurements, and the office methods of computing the regimen of flow." The work is based mainly on the hydrologic investigations of the U. S. Geological Survey.

On the regime of the streams of the dry region of Northern Brazil, O. A. Derby (*Bol. Dir. Agr. Bahia, 9* (*1907*), *No. 4, pp. 334–345*).—Measurements of stream flow for a series of years are recorded.

The drought antidote for the northwest, or the utilization of the artesian resources of New South Wales, P. Allan ([*Sydney, 1906*], *pp. 95, pls. 8, figs. 36, dgms. 3, maps 4*).—This publication discusses in some detail the conditions necessary for the occurrence of artesian water, and the location, extent, and character of the artesian basin in Australia, and more particularly in New South Wales, and gives data regarding the wells bored under the provisions of various legislative enactments. The machinery and methods used in drilling artesian wells and the methods of utilizing the water are described.

Of the 412 artesian wells recorded the 130 bored by the government are capable of irrigating with present works over 2,000,000 acres of land. "When it is remembered that, in addition to the 2,027,534 acres referred to, there are 280 private bores watering large tracts of country, besides public watering-place bores, the immense value of the artesian supply can be readily grasped, more especially as without an efficiently distributed water supply, a great portion of this arid, or semiarid, portion of the State could not be profitably occupied."

The water of the Oder Valley, Luedecke (*Das Wasser des Odertales und die Wasserkalamität der Stadt Breslau. Leipsic, 1907, pp. 36, figs. 4*).—Chemical studies of the quality of the water of the Oder River at different periods and stages and of the ground water and springs of the valley are reported, as well as an examination of the sources of contamination and means of removal.

Clean water and how to get it, A. Hazen (*New York and London, 1907, pp. VI+178 pls. 14*).—"This little volume deals with the means now used by American cities to secure clean water, and with the application of these means to new problems. Some closely allied subjects are also touched upon, including some matters of general policy, pressure, and fire service, the sale of water, and the financial management of waterworks."

Different chapters treat of impounding reservoir supplies, water supplies from small lakes, the Great Lakes, and rivers, ground-water supplies, the action of water on iron pipes and the effect thereof on the quality of the water, development of water purification in America, and the nature of the methods of purifying water.

The disinfection of sewage effluents for the protection of public water supplies, K. F. Kellerman, R. W. Pratt, and A. E. Kimberly (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 115, pp. 47*).—This bulletin reports experiments made in cooperation with the Ohio State Board of Health with the copper sulphate treatment of sewage effluents at St. Mary's of the Springs, Westerville, the Boys' Industrial School, Lancaster, and Marion, Ohio, and with the chlorin treatment at the Boys' Industrial School, and at Marion.

The importance of the destruction of pathogenic bacteria in sewage effluents, especially when the sewage is discharged in the vicinity of shellfish beds or when town and city water supplies are menaced with contamination, is discussed.

The results reported show that—

"Both calcium hypochlorite and copper sulphate have high germicidal values when acting upon partially purified sewage. Calcium hypochlorite is much more rapid in its action, is more nearly able to bring about complete disinfection at a lower cost, and is less influenced by temperature and by the presence of carbonates. It is liable to deterioration upon standing and is more disagreeable and less convenient to handle than copper sulphate.

Studies on the soils from the northern portion of the Great Plains region. The distribution of carbonates on the second steppe, F. J. ALWAY and G. R. McDOLE (*Amer. Chem. Jour., 37 (1907), No. 3, pp. 275-283*).—Previous soil studies by the same authors have already been noted (E. S. R., 18, p. 615). The present contribution reports determinations of carbon dioxid and hygroscopic coefficients of 72 samples of soils from the region named.

The results show that all soils from the second steppe are well provided with carbonates, the subsoils containing more than the corresponding surface soils and subsoils of bowlder clay being much richer than those composed of clay of lacustral origin. The carbonates are found chiefly in the soil grains of intermediate size, namely, the silts. A high percentage of carbonates was with marked regularity associated with a low hygroscopic coefficient.

The so-called alkali spots of the younger drift sheets, O. W. WILLCOX (*Jour. Geol., 13 (1905), No. 3, pp. 259-263; abs. in Chem. Zentbl., 1907, I, No. 24, p. 1702*).—The occurrence of unproductive alkali spots in soils in various parts of Iowa, Wisconsin, Illinois, and Indiana is noted. The white efflorescence on these spots consists mainly of carbonate and sulphate of magnesium and calcium and a little sodium chlorid. The magnesium sulphate is considered to be the injurious constituent.

The salt content of polders flooded with sea water March 12, 1906, D. J. HISSINK (*Het Zoutgehalte van de op 12 Maart 1906 ondergeloopen Zeeuwsche Polders. The Hague, 1907, pp. 29*).—Studies of the amount and distribution of salts added to the soil by the sea water and their influence upon the original constituents of the soil, and the effect of drainage and application of lime, etc., in the reclamation of these salted lands, are reported.

Reference of soils to fruit requirements, C. E. BRADLEY (*Better Fruit, 2 (1907), No. 1, pp. 9, 10*).—The origin, general character, and average composition of the soils of Oregon, as shown by studies made by the experiment station, are briefly discussed, as well as the draft of different kinds of fruits on the fertilizing constituents of the soil.

It is shown that fruit trees are quite heavy feeders and that they use especially large amounts of potash. "An examination of some old orchard soils of our State, recently made by the experiment station, fails to show, however, any marked depletion of potash in the soil, a significant fact as regards its lasting qualities. It is true, however, that in general trees feed deep and consequently have a greater available supply than a shallow feeding crop."

Wire-basket method of testing soils, B. C. ASTON (*New Zeal. Dept. Agr., Chem. Div. Bul. 2, pp. 11, pls. 10*).—A description of this method reprinted from Circular 18 of the Bureau of Soils of this Department (E. S. R., 18, p. 12) is given, with an account of tests of the method on two New Zealand soils of widely differing character. Generalizations are reserved until the results have been checked by field experiments.

Pot experiments with fertilizers, B. C. ASTON (*Rpt. Bien. Conf. Agr. and Past. Assocs. New Zeal., 7 (1907), pp. 35-38*).—Field experiments with turnips are reported, the results confirming in general those obtained in experiments with the wire-basket method of the Bureau of Soils noted above.

Soil fertility (*Bol. Min. Fomento [Peru], 5 (1907), No. 8, pp. 32-79*).—A Spanish translation of Farmers' Bulletin 257 of this Department (E. S. R., 18, p. 119).

Changes in the chemical composition and productiveness of peat soils under fertilization, B. SJOLLEMA (*Chem. Weekbl., 4 (1907), pp. 365-369; abs. in Chem. Zentbl., 1907, II, No. 5, p. 424*).—Studies of moor soils near Groningen on which the oat crop sickened and in some cases died are reported.

The sick soils were found to be alkaline, while the healthy soils were decidedly acid. The sick soils absorbed more soda and contained more lime soluble in carbonated water than the healthy soils. The sick soils were made healthy by adding small amounts of manganese or ammonium sulphates. The humus of the sick soils was less soluble in ammonia than that of the healthy soils, and its autoxidation was promoted by the alkaline reaction of the soil. Autoxidation may have exerted an injurious effect by (1) causing a deficiency of oxygen in the soil atmosphere, (2) production of poisonous reduction products, or (3) formation of H_2O_2 and other peroxids. The beneficial effect of manganese sulphate is ascribed to its action in decomposing these peroxids.

The applicability to India of the Italian method of utilizing silt, E. C. Buck (*Jour. Soc. Arts, 55 (1907), No. 2845, pp. 734–743*).—The Italian methods of warping and distributing muddy irrigation water so that the silt will be deposited and enrich the soil are fully described and their applicability to conditions in India are discussed. Cases of successful reclamation of rough gullied land in India by means of dams, terraces, and drains, which check the flow of the irrigation water and allow the silt to be deposited, are cited.

The hygroscopic water of the soil and the underground dew, A. B. Speranski and T. N. Krasheninnikov (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8 (1907), No. 3, pp. 281–335*).—The authors report the results of experiments which showed that when the surfaces of soils containing 33 and 23 per cent of moisture were heated more than 30 per cent of the water lost by the upper layer of the soil passed as vapor into the lower layers and was there condensed. It was found that soils whose surfaces were periodically heated lost less water into the air than those not so heated. The greater the amplitude of the temperature variations the more favorable the conditions for the formation of underground dew.

The upper dried-out layer of soil apparently protected the lower layer from loss of moisture, and when heated a part of the water of the upper layer passed into the air and part into the lower layers of the soil. On cooling, the upper soil layer absorbed moisture both from the subsoil and from the air.

In the larger number of the experiments reported, the warming of the surface of a soil of low-water content increased the transpiration from plants but decreased evaporation from the surface of the soil. Thus, while the water was in large part driven to the subsoil by heating the surface of the soil, it was still available to plants, and the limited supply of soil moisture was better utilized than when the surface was not alternately heated and cooled.

The results of these experiments indicate an explanation of the deep rooting and the drought resistance of plants on arid soils.

Observations and calculations are given to show the amount of water which will thus pass between the different soil layers under varying temperature and moisture in order to maintain the equilibrium of vapor pressure throughout the soil.

Observations on temperature variations in soil, Grohmann (*Fühling's Landw. Ztg., 56 (1907), No. 8, pp. 273–281.*)—The heat capacity of various mineral constituents of soils is discussed and studies of the temperature conditions at different depths (0.1 to 0.5 meter) in various typical soils, as well as in air and water subjected to heat rays of 2 ton-calories for 1, 4, and 9 hours, are recorded.

It is shown that the heat relations of soils are dependent upon their properties and moisture conditions, and the conclusion is reached that the temperature variations may be calculated when the amount of sunshine is known.

A review of investigations in soil bacteriology, E. B. Voorhees and J. G. Lipman (*U. S. Dept. Agr., Office Expt. Stas. Bul. 194, pp. 108*).—This review attempts to summarize the more important results of investigations on this subject reported up to the end of 1906. The review has been prepared with the hope that it "may serve to call attention to the progress already made, to indicate the possibilities of the subject, and to stimulate further and broader inquiry in this important field in this country." The subject is discussed under the following heads: Methods, bacterial decomposition of nonnitrogenous organic substance, transformation of mineral constituents of soil, chemical phases of decay and putrefaction, ammonification, oxidation processes in the soil, nitrification, deoxidation processes in the soil, denitrification, bacterial synthesis of nitrogenous compounds, nitrogen fixation (nonsymbiotic and symbiotic fixation and soil inoculation), and unsolved problems.

Studies on the bacterial content of air and soils of the Antarctic region, E. Ekelöf (*Ztschr. Hyg. u. Infektionskrank., 56 (1907), No. 3, pp. 344–370, dgm. 1*).—Observations made during the Swedish South Polar Expedition of 1901–1904 are reported, showing a rather large and varied bacterial flora in the upper layers of the soil during the warmer months of the year but a very limited bacterial content in the air of the Antarctic regions.

Experiments on the formation of nitric acid in soils, E. Murmann (*Österr. Chem. Ztg., 10 (1907), No. 13, p. 181; abs. in Chem. Zentbl., 1907, II, No. 8, p. 624*).—Experiments on a small scale are reported in which soil from which lime had been extracted by treatment with hot hydrochloric acid was mixed with varying amounts of calcium carbonate (0.1 to 2 per cent) and the amount of nitrates formed in 15 days at 12 to 16° C. determined. The results show that the addition of 0.1 per cent of calcium carbonate very greatly increased the nitrate formation in the soil. The addition of as much as 2 per cent of calcium carbonate, however, resulted in a slight decrease in the rate of nitrate formation.

The fixation of nitrogen by the nodule former, R. Greig-Smith (*Jour. Soc. Chem. Indus., 26 (1907), No. 7, pp. 304–306; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 536, II, p. 498*).—Studies of various tubercle bacteria and nitrogen-fixing bacteria under different conditions are reported.

Nitrogen-fixing bacteria were found not only in the root tubercles but in the stems of plants. The organisms found in the tubercle produced a nitrogenous slime which was assimilated by the plant on which the tubercles occurred. Those living in the more acid stem, however, did not produce this nitrogenous slime. When transferred to artificial media the tubercle organisms exhibit differences in their slime-forming capacities. "Some do not produce it upon any kind of artificial medium, others do not do so immediately, but may be induced to form it by repeated and rapid transference upon suitable pabula. The majority form more or less slime upon all kinds of saccharin media, but a few, while producing it upon artificial media with a plant basis (e. g., saccharose bean-agar), refuse to do so upon an entirely synthetic medium." The author is of the opinion that the formation of root tubercles need not be considered a result of irritating parasitic action but rather as a consequence of the production of nutrients at that place resulting in better nourishment and growth of the cells than in other parts of the roots. It was found that dextrose, levulose, saccharose, maltose, and mannite furnished a good source of carbon for the organisms, but that lactose was a very poor nutrient. It is therefore believed that the use of whey as the basis for the preparation of a medium for cultures of such organisms would lead to disappointment, thus explaining the unsatisfactory results which have been obtained with commercial cultures prepared by the whey-gelatin method employed by European firms.

The organisms from the nodules of peas at different times were apparently identical but in case of blue lupines were very variable.

The best temperature for the production of slime appears to be 22° C., although an organism obtained from Robinia was exceptional in requiring a temperature of 26° C. for most efficient action. The organisms produce the most slime on media in which the nitrogenous and slime matter approximated that found in soil water, or that which would for example be represented by 0.06 per cent of asparagin and 0.1 to 0.2 per cent of alkaline phosphate. Mixed cultures of slime-producing organisms are suggested for general use.

On the biology of nitrogen-fixing micro-organisms, SEVERIN and HELENE KRZEMIENIEWSKI (*Anz. Akad. Wiss. Krakau, 1906, pp. 560–577; abs. in Chem. Zentbl., 1907, I, No. 24, pp. 1701, 1702*).—A study of the bacterial flora and activities in soil which has been used in fertilizer experiments for 11 years is reported.

Azotobacter was much more numerous in limed soil than in unlimed and the fixation of free nitrogen was much more active in cultures inoculated with the limed soil, regardless of whether the inoculating soil had been fertilized with nitrogen or not. The cultures inoculated with limed soil showed a nitrogen fixation in 10 days of 16.75 and 18.39 mg., and those inoculated with unlimed soil of 6.83 and 7.47 mg. The nitrogen content was in general always greater in the limed soil than in the unlimed.

In pure cultures of *Azotobacter chroococcum* the fixation of nitrogen by this organism was quite small and there was no production of hydrogen or other combustible gases. The amount of oxygen consumed in crude as well as pure cultures agreed almost exactly with the carbon dioxid produced.

The organisms which produce the root tubercles of leguminous plants, G. DE ROSSI (*Centbl. Bakt.* [*etc.*], *2. Abt., 18 (1907), Nos. 10–12, pp. 289–314; 16–18, pp. 481–489, pls. 2*).—Investigations relating to the fixation of atmospheric nitrogen by leguminous plants are reviewed and a bibliography of 165 references is given; the general nature of the micro-organisms heretofore obtained from leguminous root tubercles, more especially *Pseudomonas radicicola*, and the artificial production of root tubercles are described; the need of further investigation is explained; the author's experimental technique is described; and studies of the tubercle contents and capacity of the tubercle organisms of *Vicia faba* are reported.

The author questions whether previous investigations have isolated a specific organism producing root tubercles and shows that organisms which produce tubercles and those which do not produce tubercles may be derived from tubercles of leguminous plants. He describes and explains the method of isolation and identification of a specific organism derived from root tubercles of *V. faba* which produces root tubercles and which he claims is morphologically, biologically, and culturally widely different from *Bacillus radicicola*, Beijerinck.

The author explains how the characteristic Y-form bacteroids of *V. faba* undergo a kind of vacuolation in the process of their development, and shows that this change has an important bearing on the activities of the organism under different cultural conditions.

The root bacteria of the Leguminosæ, A. RODELLA (*Centbl. Bakt.* [*etc.*], *2. Abt., 18 (1907), No. 13–15, pp. 455–461; Jour. Inst. Brewing, 13 (1907), No. 4, pp. 320–327; abs. in Jour. Soc. Chem. Indus., 26 (1907), No. 11, p. 627*).—After discussing the various views which have been held by investigators as to the nature of the bacteroids of root tubercles of Leguminosæ, the author reports investigations from which he concludes that these ramified bodies, improperly termed bacteroids, "are exclusively due to the acid generated in the tubercles of the Leguminosæ by the fermentation of the carbohydrates, and they can be obtained in artificial cultures either by similar fermentation or by the addition of organic acids, acetic, butyric, etc."

He found that when media are inoculated with root tubercles under anaerobic conditions anaerobic bacteria closely resembling the *Clostridium pasteurianum* of Winogradski, and which certainly belong to the butyric acid group, are always produced. The anaerobes of the root tubercles live in contact with aerobic organisms by symbiosis. The best methods of cultivating the organisms are discussed.

Experiments on the accumulation of nitrogen in forest soils, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 13 (1907), No. 19, pp. 580, 581*).—This is a brief note based upon investigations by E. Henry which have already been noted (E. S. R., 18, p. 550).

Fixation of free nitrogen, nitrification, etc. (*Jahresber. Gärungs-Organismen, 15 (1904), pp. 395–447*).—Reports of investigations during the year 1904 on fixation of free nitrogen, denitrification, nitrification, preservation of manure, and related micro-biological activities are reviewed.

On the assimilation of free nitrogen, J. DUMONT (*Sci. Agron., 1 (1906), No. 4, pp. 129–147; 2 (1907), No. 1, pp. 1–13*).—This is a critical review of the history and present status of scientific investigation relating to symbiotic and nonsymbiotic fixation of nitrogen, discussing especially Jamieson's theory and raising a question as to whether symbiotic fixation and assimilation of nitrogen is the only means whereby leguminous plants acquire nitrogen from the air.

A possible mission of ferments (micro-organisms) in the soil, T. F. SEDGWICK (*Internat. Sugar Jour., 9 (1907), No. 103, pp. 343–348; Estac. Expt. Cana Azúcar [Peru], Bol. 5, pp. 11*).—The function of micro-organisms in rendering innocuous the toxic substances excreted by the roots of plants and the soil conditions suited to this action are treated briefly.

Studies of the effect of varying amounts of 1 per cent citric acid on soils well supplied with carbonate of lime are reported from which the following conclusions and deductions are drawn:

"If a soil containing carbonate of lime be treated with citric acid and is still kept alkaline, a fermentation will slowly set up in the soil and solution showing that decomposition is taking place. If the fermentation is allowed to continue long enough, a deposit will be formed which, if obtained on a filter, washed with distilled water and treated with a dilute acid, will give the reaction for carbonates. This deposit will contain calcium, iron, phosphoric acid, etc. The liquid from the filtrate will be colorless and clear as water while the original citrate liquid from the soil is strongly yellow on account of the presence of iron. The clear liquid contains acetates, showing the change by fermentation from citrates to acetates. Upon standing for a long time it will not change. It is quite possible that if changes could be made to take place they would result in the final changes to the humus compounds. If the citric acid solution is allowed to remain on the soil for a number of months the soil will turn to the black of humus soils, showing that the decomposition leads to the formation of the humus compounds.

"The deductions that may be drawn from these experiments and observations are that, for these soils, the compounds in the soil produced by the action of roots and probably other organic materials of the soil are broken up through the agency of growing ferments, so that carbonates are returned to the soil maintaining its alkalinity, and certain food elements in a very soluble form are liberated: that these ferments to develop and cause decomposition must have an alkaline environment; and that the rapidity of the decomposition is in proportion to the activity of the ferment."

Treatment of soils with carbon bisulphid, B. HEINZE (*Centbl. Bakt. [etc.], 2. Abt., 18 (1907), Nos. 1–3, pp. 56–74; 7–9, pp. 246–264; 13–15, pp. 462–470; 19–21, pp. 624–634; 24–25, pp. 790–798; abs. in Jour. Chem. Soc. [London], 92*

(1907), Nos. 534, II, p. 295; 535, II, p. 388; 536, II, p. 502; 537, II, p. 572; Chem. Zentbl., 1907, II, No. 3, p. 270; Chem. Abs., 2 (1908), No. 1, p. 160).—The literature of investigations on this subject is reviewed and experiments with treated and untreated soils extending over two years are reported.

The methods used in detecting and determining carbon bisulphid in the treated soils at different stages as well as in studying the effect of the treatment on the biological and chemical processes in the soil are described. It was found that treatment with carbon bisulphid increased the yield of rye grain 40 to 50 per cent and straw 30 to 40 per cent and that the beneficial effect of the treatment extended into the second season. The yield of oats, potatoes, sugar beets, and grapes was also increased by the treatment. This increase in productiveness occurred notwithstanding the fact that nitrification was retarded to a marked extent in the sandy soils by treatment with carbon bisulphid. However, this retarding effect prevented excessive nitrification and waste in the earlier stages and disappeared after a time, being followed by an accelerated nitrification. The increased productiveness of the treated soil is, however, ascribed mainly to the action of the carbon bisulphid in promoting the activity of Azotobacter and other nitrogen-fixing organisms through preservation of the organic matter of the soil, as well as of organisms, molds, etc., which produce carbon dioxid and other acids in the soil, and thus increase the amount of available mineral constituents of plant food. The carbon bisulphid treatment also destroys plant parasites of an animal nature as well as weeds and is an effective means of overcoming soil sickness in case of grapes and leguminous plants. It was observed that the total nitrogen was considerably larger in soils treated with carbon bisulphid than in untreated soil.

The treatment of air-dry soils with carbon bisulphid increased to a marked extent the soluble potash, magnesia, and lime, while such treatment of fresh soils resulted in a large increase of sulphuric acid.

Pot experiments in which the soil was treated with bisulphid just before planting are reported which indicate that such treatment by retarding nitrification will serve as a means of judging the extent of dependence of a given plant upon nitrogen in the form of nitrates. It was found that other sulphur compounds, as well as mustard oil, and the green substance of mustard plants, acted like carbon bisulphid in retarding nitrification. This suggests an explanation of the unusually good results which have frequently been observed to follow the use of mustard as a green manure.

Contributions to natural pure cultures, F. Stockhausen (*Wchnschr. Brau., 24 (1907), Nos. 22, pp. 285–289; 23, pp. 301–304; 24, pp. 313–316; 25, pp. 325–331*).—This is a series of short reviews of the principal recent contributions to the subject of the natural conditions of development of pure cultures of organisms decomposing cellulose, reducing nitrates, producing vinegar and enzyms of different kinds, and various other reactions with special reference to the recent contributions to this subject of Beijerinck and his pupils.

The efficiency of soil inoculation in the production of root tubercles, F. L. [illegible]ens (*Science, n. ser., 26 (1907), No. 662, p. 311*).—This is an abstract of a paper read before the North Carolina Academy of Science in which "data were given concerning the inoculation of soils with liquid cultures obtained from [this Department]. From many tests conducted in various ways there was no evidence whatever that inoculation with these cultures was efficient in the production of tubercles upon legumes. The cultures employed were issued in liquid condition in hermetically sealed test-tubes, and were obtained directly from the Bureau of Plant Industry."

Soil bacteriology and the fertilizer question with especial reference to the fertilizing of clover, F. Löhnis (*Mitt. Okonom. Gesell. Sachsen, 1906–7, pp.*

31–49).—This is a general popular discussion of the bearing of bacterial activity on soil fertility with reference to "clover sickness" and other conditions affecting the growth of this plant.

Denitrification, Behn (*Jahresber. Angew. Bot., 3* (*1904–5*), *pp. 137–165*).—This is a review of the development and present status of the denitrification question.

On the conservation of nitrogen in manure, T. Macfarlane (*Proc. and Trans. Roy. Soc. Canada, 2. ser., 12* (*1906*), *Sec. III, pp. 37–43, figs. 2*).—This is a brief account of a continuation of previous experiments (E. S. R., 17, p. 345). The experiments reported in this article were made to test the effect of treatment with nitric and sulphuric acids and artificial heat on the recovery of nitrogen. The results indicate that "a complete recovery of the nitrogen in urea is quite possible if a certain quantity of acid is used and the water is expelled gradually by artificial heat." Other experiments indicated "that in the spontaneous evaporation of urine and the decomposition of its urea all the nitrogen is not eliminated in the form of ammonia, otherwise it would have been retained by the large amount of acid used."

Chicken manure as fertilizer, A. Mankovski (*Selsk. Khoz., 22, No. 10; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8* (*1907*) *No. 2, p. 206*).—The application of chicken manure suitably pulverized and sifted gave satisfactory results with wheat and millet, and with beets, cucumbers, squashes, and potatoes.

Artificial fertilizers: Their nature and functions, A. D. Hall (*Sci. Amer. Sup., 63* (*1907*), *Nos. 1640, pp. 26273, 26274, fig. 1; 1641, pp. 26293–26295; 1642, pp. 26310, 26311; 1643, pp. 26318, 26319; 64* (*1907*), *No. 1644, pp. 13–15, fig. 1*).—A reprint. The original has been noted (E. S. R., 18, p. 921).

Experiments on the application of artificial fertilizers on the chernozem of the Voronej Government, M. S. Karpov (*Vyestnik Selsk. Khoz., 1906, No. 39; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *8* (*1907*), *No. 2, pp. 210, 211*).—The author reports the results of the application, in field experiments on chernozem, of 30 per cent potash salt, superphosphate, nitrate of soda, ashes, and manure (in different combinations) under winter rye and wheat. The experiments indicate in general the profitableness of the use of mineral fertilizers under the given conditions.

Experimental field of the Moscow Agricultural Institute, 1903–1905, A. A. Kaluzhski (*Izv. Moskov. Selsk. Khoz. Inst.* [*Ann. Inst. Agron. Moscou*], *12* (*1906*), *No. 3, pp. 308–399, pl. 1*).—This report is divided into six parts treating, respectively, of winter cereals, summer cereals, grasses, potatoes, experiments with fertilizers, and experiments with straw. Fertilizer experiments with oats are described in which the effect of wood ashes was tested. It was found that moderate quantities of ashes (267.19 lbs. per acre) considerably increased the yield, while larger quantities caused a falling off in yield. Straw (rye), dry and comminuted, plowed under oats and rye lowered the yield.

Experiments to test the applicability of certain new fertilizing materials (*Deut. Landw. Presse, 34* (*1907*), *No. 65, pp. 525, 526*).—Experiments with agricultural lime and nitrogen lime by Petersen at the experiment station of Oldenburg in 1906 are briefly reported.

The use of calcium cyanamid in sugar-beet culture, A. Aulard (*Bul. Assoc. Chim. Sucr. et Distill., 24* (*1907*), *No. 12, pp. 1653–1660; abs. in Chem. Zentbl., 1907, II, No. 19, p. 1651*).—This is a brief note referring to a compilation of results of experiments in different countries, but especially in Italy. It is stated that the results show in general that the calcium cyanamid compared favorably with sodium nitrate and ammonium sulphate as a nitrogenous fertilizer for sugar beets and indicate great future possibilities for such products when the processes and plants engaged in their manufacture are more fully developed.

Under what conditions is ammonium sulphate most effective as a fertilizer? Müller (*Deut. Landw. Presse, 34 (1907), No. 67, p. 539*).—Among the conditions named as essential to the most efficient action of the ammonium sulphate are an abundant supply of potash in the soil, incorporation of the sulphate in the soil immediately after application, or when the material is used as a top-dressing application some time before the planting of the crop.

Experiments with mineral fertilizers in the Moscow Government in 1905 (*Abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 2, p. 197*).—Experiments were made with fertilizers in 9 districts. Phosphates were applied to cereals and potatoes, and gypsum to clover. Bone meal gave excellent results on rye. Gypsum increased the yield of clover by one-third as compared with nonfertilized clover.

Artificial fertilizers in peasant farming, A. Dubenski (*Selsk. Khoz. i. Lycsov., 1906, No. 9, pp. 355–373; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 2, pp. 203, 204*).—The author sums up the results obtained on demonstration fields with phosphatic fertilizers. The experiments were carried out on plats belonging to peasants. The practical importance of these tests is indicated by the fact that while in 1899 only 5 peasants applied about 7,286 lbs., in 1903 1,204 peasants applied about 714,980 lbs. of bone meal. On an average, a nonfertilized acre gave about 347 lbs. of winter rye and a fertilized one 689 lbs. Bone meal was applied at the rate of about 267 lbs. per acre.

The fertilizing value of plaster, J. Dumont (*Sci. Agron., 2 (1907), No. 4, pp. 257–274*).—The history of investigations on this subject is briefly reviewed and the action of plaster as a stimulant, plant food, absorbent, and mobilizer of plant food in the soil is discussed in some detail.

Influence of lime in connection with different phosphatic fertilizers, A. Otryzanev (*Vyestnik Selsk. Khoz., 1906, No. 37; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 2, pp. 204–206*).—Pot experiments were made with oats, applying the phosphates with lime. The effect was satisfactory only when superphosphate was used. In the presence of lime the action of Thomas slag was reduced and the action of the still more difficultly soluble phosphates (bone meal and phosphorite) was reduced to a greater extent. Similar results were obtained with winter rye.

On the use of calcium carbonate as a stable absorbent, O. Hofman-Bang (*K. Landtbr. Akad. Handl. och Tidskr., 46 (1907), No. 1, pp. 47–49*).—The manure from 28 steers was weighed for 14 days in March, 1906, and to one-half thereof 5 per cent of $CaCO_3$ (air-slaked lime) was added. The manure was placed in two piles and left for 7 months. The original weights were 4,762 kg. for the one, and 4,996 kg. for the other pile, the weight of the bedding being included in both cases, and that of 249 kg. of lime in the latter.

At the end of the trial one pile had lost 59 per cent in weight and the other 53.5 per cent, showing that the losses in the manure during storage were increased through the addition of calcium carbonate. Analyses made May 12 and September 10 showed that the limed pile contained 0.43 and 0.39 per cent of nitrogen against 0.44 and 0.43 per cent for the other pile on the two dates given.

Use of manganese compounds as fertilizers, W. Van Dam (*Chem. Weekbl., 4 (1907), pp. 391–397; abs. in Jour. Chem. Soc. [London], 92 (1907), No. 538; II, p. 649*).—When seeds were soaked in manganese sulphate solution or the salt used as a fertilizer the yield was increased and the plants had a darker green color, due, it is thought, to intensified chlorophyll formation and hence greater elaboration of organic matter.

An investigation on intensive nitrification and the establishment of high-yielding niter beds, MÜNTZ and LAINÉ (*Ann. Inst. Nat. Agron., 2. ser., 6 (1907), No. 1, pp. 15–143, figs. 4; Ann. Chim. et Phys., 8. ser., 11 (1907), Aug., pp. 439–574, figs. 4; abs. in Chem. Zentbl., 1907, II, No. 11, p. 937*).—This is a detailed account of investigations briefly reported elsewhere (E. S. R., 18, pp, 323, 430).

New nitrogenous manures (*Agr. Students' Gaz., n. ser., 13 (1907), No. 4, pp. 125–128*).—Progress in the manufacture and agricultural use of calcium cyanamid and basic lime nitrate is briefly reviewed. It is stated that since the processes of preparing these compounds depend on the production of cheap electric power they are likely to be economically produced only in countries rich in natural water power.

The preparation of nitrogen-oxygen compounds from the air by electrical means, B. SPRINGFELDT (*Elektrochem. Ztschr., 14 (1907), No. 5, pp. 91–95, figs. 11*).—Processes and apparatus proposed for this purpose are briefly described.

Nitrate facts and figures, A. F. B. JAMES (*London, 1907; rev. in Chem. News, 95 (1907), No. 2483, p. 310*).—This is a compilation of data relating to companies now in existence and their directors, date of formation, capital, dividends, reserve funds, output, etc.

Chemical manures in Egypt (*Chem. Trade Jour., 41 (1907), No. 1075, pp. 581, 582; Dipl. and Consular Rpts. [London], Ann. Ser., 1907, No. 3869, p. 30; abs. in Jour. Soc. Chem. Indus., 26 (1907), Nos. 17, p. 979; 23, p. 1248; Holland Abroad, For. Ser., 15 (1908), Jan. pp. 15, 16*).—The import and use of chemical fertilizers in Egypt are briefly discussed. The imports in 1906 are stated to have been 12,725 tons valued at $606,550.59. There has been a rapid increase in the use of manures in this country in recent years, due mainly to the work of the Khedivial Agricultural Society. The greater part of the imports is from the United Kingdom, but a large (about two-thirds) and rapidly increasing proportion is obtained from Belgium. The principal native manures, "sabak," river and canal mud, stable refuse, etc., are entirely inadequate to meet the requirements of increased production of cotton and other crops in Egypt, and the only manures manufactured in Egypt are poudrette and other sewage products prepared by a company at Cairo. There is no monopoly for the import of artificial fertilizers, and the government is encouraging the free use of chemical manures. There was a very large increase of imports of fertilizers from the United States during the year.

The consumption of Stassfurt potash salts in France and other countries, MAIZIÈRES (*Engrais, 21 (1906), No. 40, pp. 975, 976; abs. in Chem. Abs., 1 (1907), No. 15, p. 2017*).—Statistics and a plea for greater use of potash salts in France.

Phosphates and superphosphates, T. COLLOT (*Jour. Agr. Prat., n. ser., 13 (1907), No. 23, pp. 714–717; 14 (1907), No. 30, pp. 108–111*).—This article gives statistics of the production and consumption of phosphates and superphosphates, particularly in France, and a brief history of the manufacture of superphosphates in France and of the discovery of phosphate deposits, and discusses the economic causes for the extension of the uses of phosphates and superphosphates.

Wool fertilizer (*Engrais, 22 (1907), No. 34, pp. 805, 806; Jour. Soc. Agr. Brabant et Hainaut, 52 (1907), No. 33, pp. 839, 840*).—This is a brief note explaining the general character of various kinds of wool refuse used as fertilizer and common forms of adulteration of these products, including mixture with tannery refuse and with refuse solutions obtained in the manufacture of ammonia, the latter being particularly injurious on account of their high content of sulphocyanids.

Commercial fertilizers and chemicals, T. G. Hudson, J. M. McCandless, et al. (*Bul. Ga. Dept. Agr., 1907, No. 44, pp. 196*).—This is the quarterly report on inspection of fertilizers in Georgia up to August 1, 1907, containing also information regarding the nature and use of fertilizers, fertilizer legislation, pure foods, and food standards and regulations.

Commercial fertilizers, F. D. Coburn (*Quart. Rpt. Kans. Bd. Agr., 26 (1907), No. 103, pp. 126–129*).—This is a final report under the fertilizer law of 1903, and includes a financial statement and the text of the new fertilizer law (see below), which became effective September 30, 1907, and which places the inspection in charge of the director of the agricultural experiment station, taking it out of the hands of the secretary of the State board of agriculture.

Kansas law regulating the sale of commercial fertilizers, C. W. Burkett and J. T. Willard (*Kansas Sta. Bul. 148, pp. 9*).—The text of the law which went into effect September 30, 1907, is given, with explanatory notes.

The law exempts from inspection raw materials in the hands of manufacturers, salt, lime, gypsum, or the dung of domestic animals, when sold as such, and each unmixed with anything else. It requires a guaranty of minimum percentage of the following constituents: Phosphorus in phosphates soluble in water, phosphorus in reverted phosphates, phosphorus in insoluble phosphates, total phosphorus, potassium in compounds soluble in water, nitrogen in nitrates, nitrogen in ammonium salts, and total nitrogen, together with the maximum percentage of chlorin in compounds soluble in water. It also requires that the fertilizer shall contain no horn, hoof, hair, feathers, or similarly inert nitrogenous matter. "Any manufacturer desiring to do so may waive the privilege of stating the percentage of nitrogen in nitrates and nitrogen in ammonium salts.

"The manufacturer or seller shall also state the sources of the constituents of the brand of fertilizer offered for registration, which statement and the information contained therein shall be recorded for reference, but shall not be disclosed by the said director unless the materials used are such as are liable to lower the standard of the fertilizer or give it deleterious properties."

The methods of the Association of Official Agricultural Chemists are to be used in the analysis of the fertilizers. A tax of 25 cts. per ton is charged, and tags must be attached to each 200 lbs. or fraction thereof. The enforcement of the law is placed in the hands of the director of the agricultural experiment station. Violations of the law are punishable by a fine of "not less than $50 nor more than $200 and costs for the first offense, and not less than $100 nor more than $500 and costs for each subsequent offense; provided, that any seller shall be exempt from the penalty for sale of fertilizers that are below the guaranteed standard if he has a written guaranty from the manufacturer or seller of the fertilizer that said fertilizer is registered and of the guaranteed composition, if said manufacturer or seller is a resident of the State of Kansas."

The experiment station is required to publish at least annually a bulletin giving the results of inspection.

Inspection and analyses of cotton-seed meal on sale in Mississippi, W. F. Hand et al. (*Mississippi Sta. Bul. 104, pp. 25*).—This bulletin reports analyses of 242 samples of cotton-seed meal and discusses the fertilizing value of this material and the quality of the product on the market in Mississippi. The law of that State requires that cotton-seed meal shall be guaranteed, branded, and sold as (1) high-grade cotton-seed meal containing at least 6.18 per cent of nitrogen, (2) standing grade cotton-seed meal containing at least 4.95 per cent of nitrogen, and (3) off-grade cotton-seed meal containing less than 4.95 per cent of nitrogen. The analyses reported show that only 23 samples, or 9.5 per cent of the meals examined, contained a lower percentage of nitrogen than that guaranteed by the manufacturer, the discrepancies being as a rule small. "The results show, therefore, that farmers have very generally received meal practically as good or better in quality than that indicated by the guaranteed analysis attached to each bag of meal sold in the State."

Analyses and valuations of commercial fertilizers, C. S. CATHCART, J. W. KELLOGG, and V. J. CARBERRY (*New Jersey Stas. Bul. 206, pp. 35*).—This bulletin contains analyses and valuations of 261 brands of fertilizers examined during the season 1906–7, and also of 114 samples of fertilizer supplies, 9 home mixtures, and 22 special compounds.

Commercial fertilizers and poisonous insecticides in 1906–7, G. S. FRAPS (*Texas Sta. Bul. 96, pp. 24*).—Analyses and valuations of 277 samples of fertilizers examined during the year are reported, with explanations regarding the methods of conducting the inspection and a brief discussion of the composition, valuation, mixing, changes in storage, and application of fertilizers for different crops, particularly cotton, corn, rice, and potatoes. Determinations of water-soluble phosphoric acid in samples of 12 different brands of fertilizers in 1905 and again in 1907 showed a decline in percentage of this constituent during this period in almost every case, the average for the 12 samples in 1905 being 6.73 per cent and in 1907, 6.33 per cent. The amount of fertilizer sold in Texas during the year is given as 19,200 tons, not including cotton-seed meal.

AGRICULTURAL BOTANY.

Comparative tolerance of various plants for the salts common in alkali soils, T. H. KEARNEY and L. L. HARTER (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 113, pp. 22*).—In a previous publication (E. S. R., 13, p. 918) an account was given of the results of experiments upon the toxicity of certain salts of magnesium and sodium to young seedlings of the white lupine and of alfalfa.

In the present paper the results of experiments with single (pure) solutions of sodium carbonate, chlorid, sulphate, and bicarbonate, and magnesium chlorid and sulphate are given, in which their effects upon maize, 4 varieties of sorghum, 2 varieties of oats, 2 species of cotton, and sugar beets are described. Attention is called to the fact that these experiments were carried on in water cultures and that they are not directly comparable with the results which might be obtained in soil cultures, as the physical factors of the soil would doubtless modify the effect of the solutions on the plants.

It was found in general that different varieties of the same species differ considerably in their powers of resistance to the action of magnesium and sodium salts in pure solutions. Closely related species of the same genus also showed similar differences. Great differences were found to exist between different plant species in their resistance to pure salt solutions, not only as regards the absolute toxicity of the salt, but also the relative order of the toxicity of the salts. Of the 8 species investigated, maize was found on the whole to be the most resistant to pure solutions and cotton the least. Seedlings grown from fresh seed were found to be more resistant than those developed from older seed.

In addition to experiments with the single salts, various combinations were used. It was found that the presence of calcium sulphate in excess diminishes the toxicity of magnesium and sodium salts to all the plants tested, the neutralizing effect being greatest in the case of magnesium sulphate and least in that of sodium carbonate. As a rule the more sensitive the species to the pure solution, the greater was the counteracting effect of the calcium salt.

Amounts of calcium sulphate smaller than that necessary to saturate the mixed solution showed a marked neutralizing effect upon the more toxic salt, but the minimum amount of calcium sulphate capable of producing such effect remains to be determined. For the white lupine the presence of 0.5 gm. of calcium sulphate was found as effective as seven times that amount in neutralizing sodium chlorid, while for sorghum 0.1 gm. was as effective as twenty times that amount. To secure the most effective possible neutralization of sodium chlorid five times as much calcium sulphate was required in the case of the white lupine as in that of the sorghum, although the limits for these two plants were approximately the same both in pure sodium chlorid and in sodium chlorid with an excess of calcium sulphate.

While it was found impossible to compare the resistance of the different plants to pure solutions of the single salts with that of the same species in different combinations of alkali salts occurring in western soils, their behavior in mixed solutions showed a close approximation to that observed under natural conditions.

The soil preferences of alpine and subalpine plants, M. L. Fernald (*Rhodora, 9 (1907), No. 105, pp. 149–193*).—The results are given of a prolonged study of several hundred species of alpine and subalpine plants to ascertain the factors determining their distribution. The author claims that precipitation, exposure, fineness of soil particles, and water content of soils are of secondary importance in determining the presence of certain species of plants. The controlling factor is held to be the chemical nature of the soil, and striking coincidences are noted between the soil-forming rocks of mountains and cliffs and the distribution of the plants which cover them. In the regions studied it was found that the distribution of plants is largely controlled by the preponderance in the soil of potassium, calcium, and magnesium, although it was found in certain areas that soda, iron, and other elements were of equal importance in determining the range of plants.

The production of deleterious excretions by roots, O. Schreiner and H. S. Reed (*Bul. Torrey Bot. Club, 34 (1907), No. 6, pp. 279–303, fig. 1*).—Seedlings of wheat, oats, maize, and cowpeas were grown in agar in specially constructed tubes placed in glass vials attached to a clinostat. The roots developed in the agar and gave indications of chemotropism, which was attributed to deleterious substances excreted by the roots.

The authors, summarizing the results of their investigation, state that their experiments show that healthy growing plants excrete from their roots substances which have a deleterious effect upon the growth of the root. The excreta produced by the roots are so small in amount as not to be detected by chemical analysis, but the chemotropic sensitiveness of the plant demonstrates experimentally the presence of root excreta.

It was found as a rule that the excreta produced by a given plant are more toxic to plants of that same species than to others, and, so far as studied, are more toxic to closely related species than to those more distantly related.

The production of toxic excretions by the roots of the higher plants, it is held, appears to afford an explanation of some of the important phenomena connected with association, invasion, and succession of plants.

The galvanotropism of roots, Jessie S. Bayliss (*Ann. Bot. [London], 21 (1907), No. 83, pp. 387–405, figs. 4, dgms. 2*).—This is an account of experiments with seedlings of beans, maize, peas, sunflowers, pumpkins, and castor beans, in which the effect of a galvanic current upon the roots was tested.

In discussing the results the author states that there is sufficient evidence to connect the galvanotropic curvatures with those of a chemotropic character, the chemical stimuli being the acid and alkaline ions formed during electrolysis. This is supported by the fact that acids and alkalis are formed in appreciable quantities at the places where the positive and negative electrodes touch the roots. Similar curvatures to galvanotropic ones are produced by acids and alkalis placed on the sensitive zone of the root. If a piece of root tissue under a positive or negative electrode be cut out and applied to another root, the latter curves to the acid or alkaline tissue. Acids and alkalis applied to the sensitive zone of roots produce injuries similar to those produced by an electric current.

When an electrode is placed against the apex and another some distance beyond the elongating zone of the root, there is no curvature, as the acid or alkali is produced in the root cap and by diffusion affects the sensitive zone in all directions.

When nonpolarizable electrodes are used with a strength of current sufficient to produce a curvature if applied by polarizable electrodes, no curvature takes place.

The nodule organism of the Leguminosæ, F. C. Harrison and B. Barlow (*Proc. and Trans. Roy. Soc. Canada, 2. ser., 12 (1906), pt. 1, Sec. IV, pp. 157–237, pls. 26*).—The results are given of a 2 years' study with the nodule organism of Leguminosæ, in which the authors describe their experiments in the isolation, cultivation, identification, and commercial application of the organism.

About 30 species of Leguminosæ belonging to the suborder Papilionaceæ were examined and nodules found on all, with the exception of the chick-pea and *Galega officinalis*, on which no bacteria were found. No nodules were found on the roots of Gymnocladus, Gleditschia, or *Cercis canadensis* belonging to the suborder Cæsalpineæ, but mycorrhiza were present in all cases.

In cultivating the organism the authors found that a medium composed of wood ashes, sugar, and agar-agar furnished an excellent medium for growth. The morphology of the bacteria taken directly from the nodules was found to vary with the species of plant, condition of infection and growth, age and size of the nodule, and the portion of the nodule examined. In plants belonging to the tribes Phaseoleæ, Hedysareæ, and Genisteæ, the bacteria were mostly small rods with comparatively few branching and irregular cells. In plants of the tribes Trifoliæ and Vicieæ, branching in irregular forms prevailed.

The viability of *Pseudomonas radicicola* from different plants was tested, the growth taking place on ash-maltose-agar, and while the limit of viability is not yet known, the organism will probably live more than two years on favorable agar and in favorable liquid media.

Accounts are given of the preparation of nitro-cultures together with the results of experiments in their use. It was found that the material could be prepared and distributed at a cost not exceeding 25 cts. an acre as compared with $2 or more per acre charged by some commercial firms. In tests of the material distributed, 91 out of the 134 of which reports were received, were successful and showed an increased growth of crop which is attributed to the nitrogen-assimilating organism.

The use of phytin as a source of phosphorus for some of the lower plants, A. Berthelot (*Compt. Rend. Soc. Biol.* [*Paris*], *63* (*1907*), *No. 26, pp. 192–194*).—A brief account is given of experiments with yeasts, bacteria, fungi, and algæ, in which phytin was used as a source of phosphorus in the culture media. According to the author, phytin occurs in seeds, tubers, and rhizomes in combination with calcium and magnesium, and is an important reserve material for the development of the embryo and the formation of new tissues in plants.

As a result of his experiments, the author found that for the lower plants phytin is a readily assimilable source of phosphorus, and as it appears to modify the production of diastases, toxins, pigments, etc., he thinks that it would influence the formation of chloroleucites and the progress of starch production.

Lectures on plant physiology, L. JOST, trans. by R. J. H. GIBSON (*Oxford, 1907, pp. XIV+564, figs. 172*).—This is an authorized English translation of Jost's Vorlesungen über Pflanzenphysiologie, which appeared some three years ago and which the author has brought up to the close of 1906. The original was based upon a course of lectures at the University of Strassburg, and the translator has performed his work as literally as possible, without attempting to edit the material in any way. Every chapter concludes with a bibliography of the more recent and authoritative works relating to the subject treated.

Plant physiology and ecology, F. E. CLEMENTS (*New York, 1907, pp. XV+315, figs. 125*).—The present text-book is based very largely on a previous work by the author entitled Research Methods. The material has been rewritten and rearranged into chapters, in which the plant is first considered as an individual and then as a member of a plant group or formation. The book is intended for use in classes in second-year botany in colleges and universities, and it has been given two years' trial by the author with good results.

Plant breeding, H. DE VRIES (*Chicago and London, 1907, pp. XIII+360, figs. 114*).—This is a series of essays on plant breeding, with comments on the work of the Svalöf Station in Sweden and that of Luther Burbank in California. As the work of Nilsson has only been published in Swedish and that of Burbank has not yet been described by himself, the book will give an authoritative account of the work of these two men in breeding agricultural and horticultural plants. The author regards the importance of the work of Nilsson and Burbank as inestimable. These investigators and others have shown the value of individual species which may be isolated by a single selection rather than by the more tedious and less accurate method of improvement by continuous selection.

In addition to descriptions of the methods and work of Nilsson, Hays, Burbank, and others, chapters are devoted to evolution and mutation, corn breeding, association of characters in plant breeding, and the geographical distribution of plants as affecting species.

Studies in variation, G. KLEBS (*Arch. Entwickl. Mech. Organ., 24 (1907), No. 1, pp. 29–113, figs. 15*).—An account is given of studies on *Sedum spectabile* in which the influence of various factors on the number and arrangement of leaves, number of flowers, and structure of floral organs is shown. A discussion of the relation of environment to variation and a bibliography complete the paper.

American root drugs, ALICE HENKEL (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 107, pp. 80, pls. 7, figs. 25*).—Descriptions are given of 50 drugs that are found in the United States, the list including the official root drugs as well as many nonofficial ones that are generally quoted in trade lists of the country. Under each plant is given the scientific and pharmacœpial names, common names, habitat, range, description of the plant and root, and information concerning collection, prices, and uses.

Seeds and plants imported during the period from December, 1905, to July, 1906. Inventory No. 21 (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 106, pp. 125*).—This inventory represents the accessions of the Office of Seed and Plant Introduction between December 15, 1905, and July 27, 1906. It contains 2,260 items, which were introduced for experimental purposes. Among the more important collections are those of F. N. Meyer, agricultural explorer in northern China, and a number of smaller collections are noted. In addition to the names of the plants, brief accounts are given as to their habits of growth, uses, etc.

FIELD CROPS.

The problem of the unequal efficiency of our cultivated plants, S. STRAKOSCH (*Das Problem der Ungleichen Arbeitsleistung unserer Kulturpflanzen. Berlin, 1907, pp. IX+116*).—In this book the author discusses and defines what he terms the "assimilatory effect" in plants, outlines the method of its determination, and explains its application in crop rotation and crop culture generally.

The "assimilatory effect" is the quotient derived from the value of the utilizable substance which a crop produces upon a given area and the value of the quantity of plant-food elements taken from the soil to produce this substance.

The results of the author's calculations are summarized in the following table:

Estimated relative value of different crops as based on the utilizable substance produced and the plant food consumed by an average yield per hectare.

Crop	Production of starch.	Production of digestible albuminoids.	Value of product.	Value of plant food consumed.	"Assimilatory effect."	"Assimilatory effect" (rye=100).	Difference between production and consumption
	Kg	*Kg.*	*Marks.*	*Marks*			*Marks.*
Secale cereale	2,093.0	186.8	347	94.00	3.7	100	253.00
Triticum vulgare	2,684.0	274.1	449	121.00	3.8	103	328.00
Hordeum vulgare	2,492.5	156.8	426	92.20	4.6	124	334.00
Avena sativa	2,144.9	181.3	355	103.00	3.5	95	252.00
Zea mays	5,303.5	399.5	1,240	165.00	7.4	211	1,075.00

Andropogon sorghum saccharum	3,240.0	240.0	533	447.00	1.2	33	86.00

In the above table the figures referring to *Lolium perenne*, *Phleum pratense*, *Trifolium pratense*, *Medicago sativa*, *Trifolium repens*, *Trifolium incarnatum*, *Anthyllis vulneraria*, *Hedysarum onobrychis*, *Ornithopus sativus*, *Vicia sativa*, and *Andropogon sorghum saccharum* represent the green crop. In all other cases the figures given are based on the total crop of grain and straw or roots and leaves.

The forage and fiber crops in America, T. F. HUNT (*New York and London, 1907, pp. XXI+413, pl. 1, figs. 153, dgms. 4*).—This book discusses the characteristics of the forage and fiber crops grown in the United States and the results of experiments and experience as to their climatic and soil adaptation, cultural methods, insect enemies, fungus diseases, harvesting, use, and marketing. Five chapters of the book are devoted to perennial forage grasses, 1 to annual forage plants, 8 to leguminous forage plants, 1 to root crops, and 8 to fiber crops. The machines and implements used in cultivating, harvesting, and preparing some of the crops for market are described and illustrated.

The world's commercial products, W. G. FREEMAN and S. E. CHANDLER (*London, 1907, pp. VIII+391, pls. 12, figs. 408, maps 10*).—This book discusses in a popular manner the cultivation, harvesting, preparation for the market and for consumption, and the commerce of cereal, fruit, vegetable, fiber, drug, dye, spice, and other crops as carried on in different parts of the world. The list of subjects discussed in the work includes most of the common articles of commerce.

Guide to experiments conducted at Burgoyne (University) farm, Impington, and at other centers in the eastern counties, T. H. MIDDLETON (*Cambridge Univ., Dept. Agr., Guide to Expts., 1907, pp. 162, pls. 4, dgms. 5*).—The results of the experimental work carried on by the agricultural department of Cambridge University are presented in tabular form. The figures given include the crops harvested in 1906 and the experiments made in feeding live stock in the winter of 1906–7. The purpose of this publication is to present the records of experimental work in convenient form. Discussions in greater detail of the work are given in *The Journal of Agricultural Science* and in the farmers' bulletins issued by the department. These articles have been noted from time to time from these different sources.

[Soil moisture determinations], H. T. NOWELL (*Wyoming Sta. Rpt. 1907, pp. 70–114, fig. 1, charts 10*).—This is a part of the report of the irrigation engineer.

Observations on rainfall, irrigation, and evaporation were made on a number of plats growing different crops and variously irrigated. Taking as a basis the power of the plant to live and grow while the amount of moisture in the soil is at a minimum, it was found that in general alfalfa and oats subsisted with the least amount of soil moisture of any of the crops grown at the station, and these crops were followed by fall rye, field peas, spring rye, and Defiance wheat in the order named. Potatoes planted very wide apart in the rows used the smallest amount of soil moisture during their growth and field peas used the most. Defiance wheat apparently used the least moisture after potatoes, followed by alfalfa and oats, spring rye, and fall rye.

Comparisons of soil culture in this connection showed that deep plowing was beneficial, while subsoiling had no apparent effect. Shallow cultivation produced better results in retaining soil moisture than deep cultivation. Plats of grain planted in 8 in. rows retained more moisture than those planted in 16 in. rows, possibly because of the heavier stem in the 16 in. rows, the same amount of grain being sown per acre in the two cases.

[Work with field crops], B. C. BUFFUM (*Wyoming Sta. Rpt. 1907, pp. 38–58, figs. 4*).—The work with barley, sweet clover, and flax is briefly reported, and the results secured in moisture investigations are given at some length in tables.

Sweet clover proved to be the hardiest clover ever grown at the station and was found to be adapted to all kinds of soil, even to those containing large quantities of alkali and to dry uplands without irrigation. In 1905, 2 plats produced from 2 cuttings about 4.5 tons of hay per acre, while on 2 other plats a yield of 3.75 tons per acre was secured. The first 2 plats had not been irrigated, while the last 2 were irrigated for the second crop. An analysis made by the chemist of the station showed a total of 22 per cent of protein in one sample of the hay.

The experiments with flax at the station are reviewed and it is shown that in 1905 yields of flax seed from 8 different varieties ranged from 168 to 443.2 lbs. per acre.

Report of the chemists, H. G. Knight and F. E. Hepner (*Wyoming Sta. Rpt. 1907, pp. 63–67*).—In connection with brief notes on the various lines of work conducted by this department, analyses of summer and winter samples of western wheat grass (*Agropyron occidentale*), Indian millet (*Eriocoma cuspidata*), needle grass (*Stipa comata*), and prairie June grass (*Kœleria cristata*) are reported.

Experiments with oats, millet, and various legumes, A. M. Soule and P. O. Vanatter (*Virginia Sta. Bul. 168, pp. 261–290, figs. 11*).—Among the best varieties of spring oats tested were Silvermine, Texas Rust Proof, and New White Sensation, yielding 27.18, 26.53, and 25.98 bu. per acre, respectively. The seed of Silvermine, planted in 1905, contained 8.98 per cent of protein. The crop secured from this seed contained 16.20 per cent and the crop of 1906, 16.50 per cent. The seed of Texas Rust Proof, secured in 1905, contained 13.33 per cent of protein, and the resulting crop 13.81 per cent, while the crop of 1906 contained 15.14 per cent. The percentage of hulls of the different varieties of oats varied from 28 to 43 in the seed and from 30 to 43 in the resulting crop. Vetch and oats seeded in various proportions yielded from 0.90 to 1.57 tons of hay per acre, with the proportion of vetch in the green crop never more than 12.68 per cent and in many instances less than 2 per cent.

Among the best varieties of millet were German, Japanese, and Hungarian, yielding in 1905 and 1906 on an average 3.85, 2.80, and 2.42 tons of hay per acre, respectively.

Up to the present time Whippoorwill, Iron, New Era, and Black cowpeas have given the best results at the station for hay making, the average yields for the years 1905 and 1906 being 2.50, 2.43, 2.40, and 2.23 tons per acre, respectively. The following yields of hay were secured from soy beans: Ito San Yellow 2.56 tons per acre, Early Green 1.63 tons, Japanese Pea 1.90 tons, Hollybrook 2.95 tons, Mammoth Yellow 2.85 tons, and Extra Early Yellow 2.30 tons. The best average grain yields were as follows: Ito San Yellow 18.43 bu. per acre, Early Green 16.16 bu., Japanese Pea 15.20 bu., and Medium Green 14.53 bu. Inoculation tests with soy beans and field peas were without apparent results.

The best varieties of field beans grown at the station in 1905 and 1906 were Choice Navy, which made an average yield of 22.50 bu.; Burlingame, which produced 19.78 bu.; Choice Mediterranean, which produced 18.20 bu.; and White Marrowfat, which produced 17.75 bu. per acre. Canada field peas at the station have thus far failed to give a large enough yield of grain or hay to prove remunerative.

Report of the agronomist, R. E. Hyslop (*Wyoming Sta. Rpt. 1907, pp. 126–140, figs. 2*).—The lines of work conducted in the department of agronomy are briefly noted and the results of cooperative investigations of cereals by the station and the Bureau of Plant Industry of this Department in 1906 are tabulated.

Intercultural tillage of wheat and oats on ground worn out by continuous cropping resulted in maintaining a darker color in the growing crop throughout the season than on the plat where no cultivation was given. Field peas sown at a rate to supply 193,600 plants per acre produced 5,794 lbs. of straw and 606 lbs. of seed, which was a larger yield of both straw and seed than on the plats where the stand was thinner. The use of nitrate of soda in growing a plat of hulless barley apparently gave a large increase in the yield of straw and grain.

Single or continued selection in breeding work with individuals of cereals and leguminous crops, C. Fruwirth (*Ztschr. Landw. Versuchsw. Österr., 10 (1907), No. 5, pp. 477–531, pl. 1*).—This article consists of historical notes on plant selection, describes the different methods practiced, and discusses the possibility of substituting single selection for continued selection in plant breeding work based on the selection of individuals.

The classification of brewing barley from a technical and agricultural standpoint, with special reference to its nitrogen content. M. Hubert (*Bul. Mens. Off. Renseig. Agr.* [*Paris*], *6 (1907), No. 7, pp. 839–844*).—The discussion of this subject as based on the results and observations of numerous investigators leads to the conclusion that the yield and the nitrogen content of barley, as well as of other cereals, is largely dependent upon weather conditions prevailing from the blossoming period until maturity, and that special methods of fertilizing the soil can have no effect against the unfavorable influences of the season.

It is further pointed out that the cultivated varieties of barley, even those regarded as selected strains, are frequently mixtures of different species and that a chemical analysis of such a mixture, especially the determination of nitrogen, gives only average results which may differ considerably from the composition of the different individual species. Pure botanical varieties which may be separated out by Nilsson's method show a much greater regularity in chemical as well as in physiological characters than a mixture of different species.

The introduction of botanical purity is considered of advantage in the examination and classification of brewing barley and barley to be used for seed, which should show a minimum coefficient of purity of 95 per cent.

The valuation of brewing barley. E. Prior (*Amer. Brewers' Rev., 21 (1907), Nos. 4, pp. 163, 164; 5, pp. 224–226*).—The system of determining the value of brewing barley used in Vienna is described in detail.

It is pointed out that the determination of the impurities and the chaff of the barley indicates the degree of cleaning it has received, together with the percentage of kernels worth malting it contains; that the estimation of the degree of dissolution leads to conclusions relative to the behavior of the barley in the steep and, in conjunction with the protein content, also relative to the dissolution of the barley to be expected on the floor, and of the dissolution of the malt; and that the hectoliter weight, the 1,000 kernel weight, and the quantity of husk indicate the quantity of valuable substances the barley contains. By the degree of dissolution is meant the sum of the percentage of mealy kernels in the original barley and the percentage of steely kernels which become mealy after steeping and drying.

Imported low-grade clover and alfalfa seed, E. Brown and Mamie L. Crosby (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 111, pt. 3, pp. 18 pl. 1, fig. 1*).—Analyses of 61 samples of imported low-grade red clover seed, 5 samples of high-grade red clover seed, and 16 samples of imported low-grade alfalfa seed are reported and described.

The analyses of the low-grade clover seed showed the following average results: Red clover seed 74.06 per cent, other seeds 12.17 per cent, dirt and broken seed 13.83 per cent, kinds of weed seeds 29.7, weight of 1,000 red clover seeds 1,105.5 mg., germination of red clover seed 58.03 per cent, price per 100 lbs. at which seed was imported $7.61, seed that germinated in sample 43.16 per cent, actual cost of 100 lbs. of red clover seed that germinated $20.39. The 5 samples of high-grade red clover seed gave the following average results: Red clover seed 97.73 per cent, other seeds 0.85 per cent, dirt and broken seed

1.42 per cent, kinds of weed seeds 5.2, weight of 1,000 red clover seeds 1,580 mg., germination of red clover seed 98.8 per cent, price per 100 lbs. at which seed was offered for sale $15.05, seed that germinated in sample 96.55 per cent, actual cost of 100 lbs. of red clover seed that germinated $15.58. Many of the low-grade samples contained dodder, while in the 5 high-grade samples no dodder was present.

Analysis of 16 samples of imported low-grade alfalfa seed gave the following average results: Alfalfa seed 86.44 per cent, other seeds 4.89 per cent, dirt and broken seed 8.68 per cent, kinds of weed seeds 15.75, weight of 1,000 alfalfa seeds 1,580 mg., germination of alfalfa seed 51.47 per cent, price per 100 lbs. at which seed was imported $7.63, seed that germinated in sample 44.31 per cent, actual cost of 100 lbs. of alfalfa seed that germinated $18.78.

Growing alfalfa without irrigation in Washington, E. E. ELLIOTT (*Washington Sta. Bul. 80, pp. 32*).—This bulletin presents in a popular form the results of practical experiments carried on at the station farm, together with information on the practices of progressive farmers in the State.

Ten years' work has shown that on virgin soil a fair stand of alfalfa was readily secured and that a failure to secure a perfect stand was due to insufficient seed and improper methods of seeding. The field used yielded heavier crops from year to year and any cultivation given the ground gave good returns. A profitable second crop was secured in only one instance. The average annual value of the crop is estimated at about $10 per acre, although it is stated that in 1897, 1899, and 1900 it was considerably more.

In one experiment seed secured from Colorado gave much better results than seed from an unknown source. Good results have also been secured from Turkestan alfalfa.

A brief statement of approved methods of cultivation concludes the bulletin.

Farmers' institute bulletin, 1907, W. R. PERKINS (*Mississippi Sta. Bul. 103, pp. 16, figs. 8*).—This is a popular bulletin briefly outlining the methods of corn improvement and corn judging, and discussing the subjects of seed corn growing and testing.

The fibers of long-staple upland cottons, H. A. ALLARD (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 111, pt. 2, pp. 7, pls. 2, figs. 3*).—This bulletin discusses briefly the apparent lack of uniformity of cotton fibers, and the true nature of the longer fibers.

With reference to the so-called long fibers the author states that "they are not longer fibers as they have been generally considered, but are caused by more or less curling and interweaving, which results in the pulling out of fibers from adjacent seeds."

Artificial fertilizers for cotton in the central provinces, D. CLOUSTON (*Agr. Jour. India, 2 (1907), No. 2, pp. 116–122*).—Nitrate of soda was applied at the rate of 130 lbs., sulphate of potash at the rate of 65 lbs., and superphosphate at the rate of 260 lbs. per acre, supplying 20, 35, and 50 lbs. of nitrogen, potash, and phosphoric acid, respectively. The season's results showed that nitrogen was the most important plant food on this particular black-cotton soil. When superphosphate and potash were applied with it there was a considerable gain, but the value of the increase was insufficient to cover the cost of these two substances. The plat receiving nitrogen alone produced 760 lbs. of seed cotton per acre, while the complete application produced 870 lbs., and nitrogen with either superphosphate or potash 800 lbs. per acre.

The milling properties of oats, R. B. GREIG and W. M. FINDLAY (*Jour. Bd. Agr. [London], 14 (1907), No. 5, pp. 257–268*).—Observations on the milling properties of oats showed that within the same variety clay soils produce a grain of high milling power and peaty soils one of low milling power. The difference is considered as probably due to the thinner husk and better matured kernels from clay lands. A dry season was found favorable to meal production, the grain containing less moisture and being better matured. Excessive nitrogenous manuring tended to thicken the husk, to delay ripening, and to decrease the percentage of water in the grain. Phosphates and potash appeared to increase the proportion of kernel and certainly accelerated ripening. It is stated that if oats are not carefully graded loss occurs because grains of unequal size do not dry uniformly, in shelling the larger grains are broken and the smaller escape, and very small grains are blown away with the husks.

A comparison of the milling properties of different varieties indicated that the milling value depends on the thickness of the husk and the shape of the kernel. It is pointed out that the relation of these two factors is not always apparent, and by way of illustration attention is called to the fact that the husk of Newmarket oats is actually thicker than the husk of Potato oats, although the proportion of husk in the Newmarket is less than in the Potato, so that Newmarket in spite of a thicker husk is the better milling variety. Varieties in which the kernel fills up and is closely covered by a thin husk have the highest milling value. It is stated that owing to the shape of the kernels of Newmarket, Abundance, and Thousand Dollar these varieties compete successfully as milling oats with Potato and Scotch Birlie. Storm King has a short pointed kernel and thick husk and is for this reason a poor milling variety.

Experiments on transmission in the potato, E. GRABNER (*Ztschr. Landw. Versuchsw. Österr., 10* (*1907*), *No. 7, pp. 607-647*).—The results of cooperative investigations carried on for several years showed that tubers from the best developed hills were more productive than those from smaller hills, and the conclusion is drawn that the yielding capacity may be increased by selecting tubers for seed from the heaviest hills.

Comparisons of the same quantity of seed by weight of small and large tubers resulted in the obtaining of the higher yields from the small tubers. The determination of size from the weight of the seed was not applicable in these experiments, nor was the starch content as based on the specific gravity of the seed tubers transmitted. The average results, however, indicated that starch content is a varietal character, and it is believed that its transmission, although influenced by several factors, is very probable.

Observations on the form of tuber in its relation to yield and starch content showed that within the variety globular seed tubers influenced the starch content while cylindrical tubers influenced the yield. No similar connection was observed between varieties with globular tubers and those of which cylindrical tubers are typical. It was found difficult to change the form of the tuber when this appears as a character of the variety.

Selection of potato varieties for distilleries, G. ROSSMAN (*Abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], 7 (*1906*), *No. 6, pp. 725, 726*).—Observations made at different experiment stations showed that larger yields of potatoes and a higher quality of tubers were secured on compact soils than on sandy soils, and that varieties with red tubers grew especially well on clay soils, but did not make as good a growth under these conditions as white varieties on light soils.

The violet Solanum commersoni, A. and P. ANDOUARD (*Bul. Sta. Agron. Loire-Inf., 1905-6, pp. 30-33*).—Several cultural experiments with the violet variety of *Solanum commersoni* are reported. In one instance an average of a little over 3 kg. of tubers per hill was secured from 40 hills, and in another test the yield corresponded to 29,000 kg. per hectare as compared with 10,000 kg. for the Early Rose potato grown under the same conditions.

Investigations on the morphological influence of fertilizers on the potato, P. Vageler (*Jour. Landw., 55 (1907), No. 3, pp. 193-214*).—The experiments were conducted on a newly reclaimed moor soil. Potash and phosphoric acid were applied at the rate of 300 kg. and nitrogen at the rate of 100 kg. per hectare, and these substances were given in different combinations. The potatoes were planted in rows 70 cm. apart, with 30 cm. between plants in the row. The methods of obtaining material for study and the technical processes of the investigation are described.

It was found that nitrogen on this kind of soil, with a precipitation of 1,200 mm., tends to increase the number of stems in the plant, and that the length of the stems is also favorably influenced. The effect upon the length of the stems, however, is not so marked as upon their number. This influence of nitrogen seemed to be brought about even when the other plant food elements were lacking in the soil. Potash also showed its influence on the number of stems, especially when phosphoric acid and nitrogen were lacking, but phosphoric acid under the same conditions had a greater influence on the length than upon the number of stems. It was found that when either potash or phosphoric acid was not included in the fertilizer application better results were obtained when potash was given than when phosphoric acid was applied.

With reference to the structure of the leaf, it was found that a complete application of minerals reduced the thickness of the leaf and that the thickness of the epidermis depended upon a large supply of potash and to a smaller extent upon the supply of phosphoric acid. Nitrogen remained almost neutral in this connection. The thickness of the loose parenchyma was found directly proportional to the quantity of the complete fertilizer used, while in the case of the palisade parenchyma the proportion was inverted.

Potato experiments in progress for 5 years on the experiment fields of the Podolsk agricultural society, F. Lubansky (*Abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 2, p. 231*).—The results secured are summarized in the following table:

Average results with different varieties of potatoes compared for 5 years.

Varieties.	Yield of tubers per acre.	Percentage of starch per acre.	Yield of starch per acre.
	Bu.	*Per cent.*	*Lbs.*
Kösternitz	353.07	20.6	435.99
Kaiserin Augusta	346.88	20.8	431.98
Wohltmann	341.70	21.0	485.90
Silesia	337.91	21.5	480.67
Maerker	336.80	20.6	415.93
Juwel	331.61	20.4	405.23
Imperator	300.60	19.4	438.83

The action of manganese on the potato and the sugar beet, A. Grégoire, I. Hendrick and E. Carpiaux (*Bul. Agr. [Brussels], 23 (1907), No. 6, pp. 388-394*).—The action of manganese on different crops as determined by various investigators is reviewed, and the authors' results with potatoes and sugar beets are briefly reported.
